EVALUATION OF END-RESULTS OF ACUTE ANTERIOR POLIOMYELITIS

Robert L. Bennett, M.D., Warm Springs, Ga.

• *Poliomyelitis does not actually have a chronic phase, when considered in terms of static functional capacity and reaction to stress. The end-results of this disease can be evaluated any time after the period of rapid recovery has taken place and the patient is old enough chronologically, and in duration of illness, to have had all the necessary treatment. This evaluation, which must be on an individual basis, must include not only the degree of physical independence but also the patient's mental adjustment to his residual physical handicap. Evaluation can only be carried out by the physician who, considering all the many factors determining recovery, judges without bias.*

The desired end-result in poliomyelitis is achieved when (1) the patient has obtained or regained the highest possible degree of safe physical independence within the limitations imposed by factors over which there is no human control and (2) the patient has made an intelligent adjustment to his residual handicap. The degree to which this dual goal has been reached can be evaluated only by the physician who, considering all factors that molded the end-result, judges without bias. The purpose of this paper is to discuss factors that determine the end-results, regardless of treatment, and some of the more important criteria by which the effectiveness of treatment may be determined.

We must first decide when we are justified to judge end-results. Experience has taught us that poliomyelitis actually has no chronic phase, if we speak in terms of static functional capacity and reaction to stress. Poliomyelitis is forever to those who have significant after-effects, and the deforming possibilities of age and activity are with them as long as they live. We can only state arbitrarily that an evaluation of end-results may be made at any time after the phase of rapid recovery has taken place and the patient is old enough chronologically, and in duration of illness, to have had all necessary treatment.

Factors Determining Recovery

No end-results can possibly be graded as good, bad, or indifferent, particularly when judging the effectiveness of treatment, unless factors that modify recovery, regardless of treatment, are also considered.

Site and Extent of Central Nervous System Involvement.—Each muscle has what might be called a normal complement of anterior horn cells arranged in fairly well-defined columns within the anterior horn of the spinal cord. Some muscles are innervated by short columns of cells extending over little more than one segment of the spinal cord. Other muscles may have long columns extending over five or even six segments. Therefore, a relatively mild destruction of anterior horn cells extending over one or two levels of the spinal cord might completely denervate muscles with limited normal innervation and largely spare those with multiple levels of innervation. While each muscle is important in some phase of functional activity, certainly it must be admitted that all muscles are not of the same importance. Lesions at the cervical level are more apt to cause greater loss of functional capacity than lesions of a comparable size at thoracic or lumbar levels. Therefore, the site and extent of the irreversible damage to the central nervous system must determine to a most significant degree the eventual recovery of physical activity, regardless of treatment.

Availability of Adequate Medical Care.—It must be accepted that adequate medical care will minimize the after-effects of this disease. Adequate care must be adequate total care. The finest convalescent care cannot overcome the faults of management of care in the acute stage nor wholely protect the patient from inadequate or faulty care in the chronic stage. Despite the most conscientious effort, recovery may be limited because of limited personal and community resources. Epidemics tax the resources of even the best-prepared community, and only minimal facilities are available throughout the country for those persons with severe involvement.

Medical Condition of Patient.—If the medical condition of the patient prohibits the use of care necessary to optimum recovery of his neuromuscular system, weaknesses will persist and deformities will develop that could otherwise have been prevented. A patient

confined to a respirator simply cannot have all the necessary treatment for his skeletal muscular involvement that would otherwise be possible. At any time during the patient's life medical problems entirely apart from the after-effects of poliomyelitis might seriously interfere with his continued recovery or his maintenance of muscular strength and skeletal alignment.

Age of Patient at Onset of Acute Anterior Poliomyelitis.—From a structural standpoint, the infant that develops significant muscular weakness is a far greater problem than the adult with comparable weakness. Despite the finest treatment, such an infant must develop certain changes in structural alignment as he grows taller and increases in both weight and activity. Growing bone demands balanced musculature for its alignment, and, regardless of the best supportive apparatus available, some degree of deformity must result. The infant and youngster cannot be expected to appreciate the necessity for restriction of activity and the avoidance of abnormal patterns of movement. They therefore tend to develop marked muscle imbalance, despite the most conscientious supervision. Their response to specific muscle reeducation is limited for the same reason. Psychologically, each age has its own problems. The teen-ager is particularly difficult to cope with because of his interest in his physical self at this age. His adjustment to this loss of physical capacity is extremely difficult. The infant, never knowing normal physical capacity, has a somewhat easier time accepting his limitations. The young adult, man or woman, particularly when married and just starting out on a career, finds physical handicap extremely difficult to accept and is plagued by the fear of insecurity and inadequacy. Structural growth, nancial insecurity, and the loss of sense of personal rth may be far greater problems influencing the nd-results than the actual physical handicap caused by muscle weakness alone.

Personality of Patient, His Family, and His Community.—I think it is only fair to say that, if a patient with significant and lasting muscle weakness makes a good physical and psychological adjustment to his handicap, a great share of the credit must be given to the patient, his family, and his community. This statement is not meant to detract from the credit due the physician but rather to emphasize the importance of the attitude and responsibility of the patient and all those about him who mold the end-results, from a physical standpoint as well as socially, vocationally, and economically. Without their complete cooperation, the physician alone is incapable of maximum results, regardless of his knowledge and skill. This is particularly true of the young child who must be kept under the disciplines of restricted activity and tedious home routines for long years after the period of rapid recovery has taken place. It is hard for families to understand that this monotonous program is designed simply to keep the child growing as straight as possible until structural security is assured by mature bone growth or until necessary orthopedic surgery can be carried out at the proper age. Patients cannot be hospitalized endlessly, nor can the doctor and therapist in an outpatient department be responsible for total care. The patient must be returned to his home in a reasonable period of time, and he and his family must accept most of the responsibility of continued care.

Criteria for Judging End-Results

It should be apparent to each of us that we cannot judge the effectiveness of treatments by setting forth a list of functional activities and arbitrarily deciding that a good result means the accomplishment of a high percentage of these activities and a poor result the accomplishment of but a few. A good result, or a poor result, depends entirely on what was done with what was left to work with, not in terms of the percentage of normal capacity regained but in terms of the maximum response such involvement will allow under what might be considered ideal circumstances. Many results that might be considered poor when compared to the average response might actually be excellent if we consider the tremendous odds against which these particular patients were fighting. On the other hand, results quite acceptable to average patients should be considered poor if the patients evaluated have had every advantage and have made little use of them.

The success or failure of the care of the after-effects of poliomyelitis might well be determined by the answer to one basic question: Has the patient, through treatment, obtained maximum safe and practical functional capacity possible within the limits imposed by the factors that determine end-results, regardless of treatment? This question fairly indicates the objectives of treatment and, therefore, the physician's goal in his care of his patient. The degree to which this goal has been achieved can be determined only after the consideration of the following six points by which the physician should analyze his results.

Pattern of Residual Weakness.—The after-effects of poliomyelitis show characteristic patterns of residual weakness. Good treatment can favorably modify these patterns, but only to a moderate degree. Poor treatment not only exaggerates these patterns but actually causes patterns that can be identified as due to faulty treatment. This point is not easy to discuss, because we are immediately faced with the knowledge that we are actually unable to determine the precise damage done by the virus and must accept the fact that any distribution of anterior horn cells could be involved. Few diseases permit us to excuse our mistakes so easily. However, long experience with this disease has shown us that identical combinations of specific muscular weaknesses occur so frequently as to be expected, and deviations from these combinations must be viewed with suspicion of faulty care. Clinical and pathological studies by many investigators have repeatedly shown the striking combinations of muscle weaknesses that appear to be characteristic of the after-effects of poliomyelitis. This was noted as early as 1908 by Lovett and Lucas[1] and was well discussed in a more recent paper in 1955 by Sharrard.[2] Actually, little experience is necessary to state that, if a bizarre pattern exists or if isolated severe muscle weakness is found in a bodily segment otherwise not involved, we have good reason to believe that the damage was done by extrinsic factors of overwork or disuse rather than neuron distruction due to virus invasion. Isolated weakness in the serratus and in the triceps surae and muscle imbalance in the abdominal muscles occur so frequently from these causes that they need no further discussion. Other patterns are far more difficult to detect and require a great deal of experience on the part of the evaluating physician. In many instances only repeated observation of the habit patterns of movement in individual patients will bring out the true reason for faulty recovery.

Musculoskeletal Deformities.—Except for atrophy of muscle, which must follow permanent denervation, and retardation of skeletal growth, the cause of which is not completely understood, all other deformities of the musculoskeletal system are at least theoretically preventable by proper care. However, some degree of deformity must develop in bodily segments if residual weakness exists and necessary activity brings about abnormal stress on these bodily segments. Despite adequate mobilization, muscle reeducation, graded activity, and externally applied supports, some degree of structural deformity will take place in the growing child and even in the adult if muscle weakness persists. The physician, however, must accept the responsibility of minimizing these deformities. Through accepted methods of care the physician must show proof that he has anticipated the development of significant deformities by evaluating the causes of these deformities and doing everything possible to prevent their development by properly timed conservative and surgical methods. Since the existence of deformities definitely limits the goal of maximum possible functional recovery and the patient's acceptance of his physical handicap, the evaluation must indicate the degree to which the deformities have been anticipated and corrected. Because it is impossible to prevent or correct all deformity, the evaluation must show the extent to which the physician has recognized these deformities and made an effort to overcome them. The physician who attempts to evaluate these end-results must obviously know the pathogenesis of deformity and the accepted methods for prevention or correction.

Apparatus.—The use of various types of orthotic devices has now become an accepted part of both convalescent and chronic-phase care. Certainly the effectiveness of any method of treatment must never be evaluated solely in terms of the amount of apparatus used. Great advances have been made in the design, weight, and fitting of supportive and assistive apparatus, and this apparatus may be essential to the achievement of maximum safe and practical functional capacity and the patient's intelligent acceptance of his physical handicap. It is just as great a fault not to use an apparatus that is necessary as it is to apply an apparatus that should not have been used at all.

Orthopedic Surgery.—It should be pointed out that there is no evidence to show that ideal treatment decreases the number of necessary and effective orthopedic surgical procedures. Ideal treatment, on the other hand, should have eliminated the need for unnecessary surgical procedures and, at the same time, should have assured maximum results from those procedures that were necessary. The effectiveness of any form of treatment should never be based on the number of orthopedic surgical procedures that were used. Such surgery is frequently necessary to increase functional capacity and structural security. Like the proper use of necessary apparatus, necessary orthopedic surgery should also be considered a part of good over-all care. If orthopedic surgery was done, an end-result evaluation must determine whether the surgery was really necessary and whether it actually accomplished the purpose for which it was intended. Orthopedic surgery cannot be expected to cure all the ills of muscle weakness, muscle imbalance, and structural deformity, but, on the other hand, there must be every evidence that surgery was properly timed and the procedures used were well thought out and executed. Like all other forms of treatment, surgery can cause more harm than good if improperly applied.

Evidence of Specific Functional Training.—The person with severe involvement cannot achieve effective functional capacity without skilled training. The degree to which he develops both safety and endurance for the necessary physical activities must reflect the training that he has had. The finest surgical procedures, or the finest apparatus, can be of little value unless the patient is taught how to profit from the results of such procedures or apparatus. The patterns of physical activity not only must be safe and practical but also must be acceptable to both the patient and the individuals with whom he must live. Only the physician well versed in the possibilities of developing functional capacity in the person with severe involvement can possibly evaluate this component of the end-result.

Attitude of Patient Toward His Handicap.—The last, but in many ways the most important, point to consider is the patient's personal reaction to his handicap. The medical-care program, to be considered really adequate, must accept the responsibility of assisting the patient to make an intelligent adjustment to his ultimate handicap. Even minimal physical handicap requires some degree of adjustment on the part of the patient. To adjust adequately, the patient must be sure in his own mind that he has all the treatment necessary. He must know the full extent of his limitations; he must be able to interpret his own limitations not only in terms of the normal individual but in relationship to those with more severe and less severe physical handicap. The extent to which the patient has adjusted vocationally, socially, and recreationally must be the points by which he is judged in this phase of the end-result of his disease.

Summary and Conclusions

An evaluation of the end-results of poliomyelitis must be made on the basis of individual patients. An adequate end-result may be said to have been achieved when the patient has obtained or regained the highest possible degree of safe physical independence within the limits imposed by factors over which there is no control and, in addition, when the patient has made an intelligent adjustment to his residual physical handicap.

Since we are unable to determine precisely the actual damage to the nervous system by the invasion of the virus and its uncontrollable after-effects, we find it easy to excuse our bad results on the grounds of unpreventable pathology.

The multiple variations of involvement make a listing of functional achievements a formidable, if not impossible, task. If we add to these variations of muscular involvement and their skeletal after-effects the even greater numbers of variations in patients' age, background, personality, and environment, the listing of expected achievement becomes truly impossible. The degree to which both the patient himself and his medical supervisor have taken advantage of the full possibilities of recovery can be judged only by the experienced but unbiased physician after full consideration of all factors that determine the ultimate recovery.

PREVENTION OF PSYCHIATRIC ILLNESSES

Paul V. Lemkau, M.D., New York

• *Epidemiological studies show that prevention, not primarily treatment, appears to be the logical long-term solution to the mental illnesses. Past investigations reveal this particular group of diseases may fall into three etiological classifications: organic brain damage, individual stress, and what might be called group stress resulting from cultural patterns.*

The prevention of somatic pathology is fairly well understood, especially where there is a single causative factor. The detrimental effects of individual stress might be obviated through much of our present-day knowledge of personality formation. It is in the area where social customs seem to be the dominating determinant of psychiatric illness, however, that new research is needed.

The major successes in the prevention of disease have been in dealing with that group in which there is one outstanding and overwhelming cause for the disease.[1] For the most part, these successes have been in the prevention of diseases of bacteriological or viral origin in which the essential etiological factor is an invasion of the body by an external agent. We have had much less success with illnesses that arise within the body itself, such as arthritis, cancer, diabetes, and arteriosclerosis. In these, we probably deal not with a single overwhelming cause but with a series of causes that must in some way act together to produce disease.

It is true that these two general groups of illnesses cannot be entirely separated, and that more and more we begin to recognize, under the leadership particularly of Dubose,[2] that even those diseases fundamentally related to the invasion from the outside depend upon the condition of the body invaded. Dubose, by means of ingenious experiments, is bringing back into focus the common folk ideas that drafts cause colds; that, in other words, overexposure predisposes the body to external invasion. The relationship between recent severe physical activity and the appearance of paralysis in poliomyelitis is another case in point. It is well recognized, particularly in tuberculosis, that psychological stresses in the family, at work, and elsewhere seem frequently to be related to the appearance of actual illness.[3]

In the mental illnesses, the concept of the single important cause of disease is more difficult to apply. Indeed, one psychiatrist, Dr. Robert Felix, has made the statement—not entirely seriously—that schizophrenia acts like tuberculosis in which the bacillus is absent. He is saying that it is at least possible that schizophrenia is a reaction to complicated, difficult, stressful life situations; that for this disease it is these life situations themselves that are the cause; and that no adjunctive bacterium needs to be present to give the resulting illness a particular charcter.

The issues of the prevention of psychiatric illnesses are extremely complex. One reason for this complexity is that we tend to think of psychiatric illness as a unit, instead of considering the multiple and relatively independent illnesses that are included in that unit. There are some psychiatric illnesses in which the etiology is as clear as it is in the physical diseases in which an invader of external origin is of overwhelming importance. For these psychiatric illnesses, prevention is as easy to consider as it is in connection with typhoid or pneumonia. There are other illnesses, however—and these are the ones that give the greatest difficulty—in which there is no single destructive invasive cause.

Another problem that makes it difficult to think about the prevention of psychiatric illness is the extraordinary fluidity of the field. In the last 30 years, psychiatry has seen the introduction of many new types of treatment. It appears fair to say that research and theory have not entirely been able to keep up with empirical advances in the field. We have gone through a period of innovations in shock therapy using insulin, pentylenetetrazol (Metrazol), and electricity; yet in none of these has the function of the treatment in controlling psychiatric illnesses been completely explained. We have seen the introduction of brain surgery for the relief of psychiatric syndromes, but we are still without an adequate and complete explanation of the effectiveness of these operations in some cases. More recently, there has been the introduction of drugs such as lysergic acid and its derivatives and some of the hormones and hormone-like substances, which, under certain circumstances, induce psychotic behavior in human beings. In addition, the extremely rapid introduction and widespread use of the behavior-regulating drugs, chlorpromazine and the Rauwolfia derivatives, have again produced a therapeutic agent the mechanisms of whose action are not clearly understood. Certainly the relationship of these drugs

Read before the Section on Preventive and Industrial Medicine and Public Health at the 105th Annual Meeting of the American Medical Association, Chicago, June 14, 1956.

to, for example, schizophrenia, is far different from the specific relationship of insulin to diabetes mellitus. Yet, it is likely that the length of time it has taken to understand carbohydrate metabolism and the effectiveness of insulin in its regulation resembles the length of the time it will take for psychiatric study and research to solve the problem of the effect of the behavior-regulating drugs on the function of the brain.

In this year of the 100th anniversary of Freud's birth, it is well to recognize also that it has been but 40 or 50 years since the introduction of his concepts of the psychogenesis of the mental illnesses, and that there have been, in that time, numerous corrections and reformulations of his ideas. It is safe to say at the present time that psychiatric research and theory have not, by any means, caught up with the numerous hypotheses he postulated. In other words, psychiatry remains without a completely sound theory of either the causation of the psychogenic mental illnesses or the effect of empirical treatment.

Findings of Epidemiological Research

There is another aspect of rapid change in the psychiatric field to be accounted for in any discussion of the prevention of psychiatric illnesses. This relates to the findings of epidemiological research. The problem appears in such overwhelming proportions that the need for its control has become perhaps the major issue in the public health programs of the future. Some of these findings are very trite; for example, that half of the hospital beds in our nation are occupied by patients with psychiatric illnesses, most of them chronic. In addition, there are the data concerning the prevalence of psychiatric illness not requiring hospitalization. The two best current studies of this field appear to indicate that psychiatric symptoms severe enough to require treatment may be present in as much as 30% of the population.[4] Older studies about the prevalence of psychiatric complaints in the practices of physicians are so well known that their findings need not be repeated here.[5]

Epidemiological studies have, however, gone beyond merely pointing with alarm to the large number of cases existing. There are studies that indicate that mental deficiency, epilepsy, cerebral palsy, and certain other illnesses are probably directly related to various obstetric complications, particularly hypertension of pregnancy, eclapsia, and bleeding in the third trimester.[6] It appears clear that the prevention of these more or less static conditions that are due to inadequate development, or to direct damage to central nervous system tissue, can be prevented to a considerable degree if the problems of obstetric care can be solved.

Epidemiological studies have gone further than this and have demonstrated that there are certain groups in the population that must be the subject of particular concentration if mental illnesses are to be prevented. It is quite clear that the underprivileged group in the population—underprivileged economically and educationally, probably nutritionally, and certainly in housing opportunities—produces far more of the mental illnesses of all kinds than one would expect if these illnesses were evenly distributed in the total population.[7] This leads to the consideration of cultural factors that in some way reduce the threshold for the appearance of mental illnesses in these underprivileged groups.

Thus, in any approach to the problem of the prevention of the psychiatric illnesses, it must be recognized that this group of diseases includes syndromes in which there is an overwhelming cause, for example, encephalitis or brain trauma; illnesses in which there is a nutritional or metabolic disorder, for example, macrocytic anemia and, in a sense, also arteriosclerosis; and illnesses that are exclusively due to chronic reactions to debilitating life circumstances of a personal, as well as of a broader cultural, type.

Opportunities for Prevention

With present knowledge and the rapid extension of theory and laboratory knowledge in this field, what are the present opportunities for prevention? The easiest group of illnesses to deal with is that due to a single cause arising outside the individual. There is nothing new in the concept of the prevention of paresis by the prevention or early treatment of syphilis. If the basic disease, syphilis, is controlled, paresis cannot occur. If there is no tuberculosis, there can be no tuberculoma of the brain, with a consequent behavior disorder, nor tuberculous meningitis, with residua due to destruction of the brain cortex. If there is no traumatic destruction of brain tissue, there can be no post-traumatic psychosis. For the most part, the prevention of this kind of mental illness does not lie in the hands of psychiatrists. It lies directly at the door of public health and, with a few notable exceptions, public health has handled this problem well.

Individual Stress.—The psychiatrist, however, is deeply concerned with the alleviation of the individual and cultural stresses on the person that lower the threshold for the appearance of illness. It must be admitted that in this area the case rests almost entirely at the present time on hypothesis. There is a growing literature on experiments in animals showing that long-continued severe stress upon the individual will cause overgrowth of certain hormone-producing glands. These data make more understandable the precise mechanisms by which the threshold of response, with disease or symptom-reactions, is lowered by long-continued stress. It cannot be said, however, that this mechanism is entirely understood at the present time and, as has been pointed out already, there are undoubtedly many such mechanisms that would have to be considered in order to understand all of the psychiatric illnesses that can be distinguished, even within this field of psychogenic illnesses.

The problem of prevention then becomes the avoidance of stress that is so great that it exceeds the capacity of the individual to deal with it and eventually lowers his ability to withstand the appearance of psychiatric illness.[8] At the level of individual stress, it is believed that the best work can be done during the period of rapid structuralization of the personality that takes place in childhood. The newer experiments on the effect of isolation of infants and very young children, which indicate that inadequate stimulation of innate capacities can lead to the atrophy of these capacities, tend to point to the importance of early childhood as an area for preventive work.[9] Thus, it would appear that every child, every infant, ought to have a person near to stimulate him to use all of the capacities he has available—capacities to move, capacities to learn, capacities to react emotionally, capacities to love; all these must be exercised lest they atrophy and thus become no longer available for later development. This avoidance of understimulation, both intellectually and emotionally, is not, however, confined to early infancy. It can also be shown that the elderly who are denied social intercourse and stimulation tend to lapse into psychotic disorders more often than those living in better and more stimulating social circumstances.[10] In short-term experiments, it can be shown that healthy young adults, if drastically denied any outside stimulation, will quickly react with psychiatric symptoms such as hallucinations and delusions.[11]

There appear to be many opportunities for the prevention of unnecessary stress on the individual in the parent-child relationship. The study of child development shows that certain types of behavior are normal in children but are also considered bothersome, unhealthy, and embarrassing by many in our culture. For example, many mothers are excruciatingly embarrassed when their children of 3 throw temper tantrums at a supermarket, and yet it can be safely predicted that 80% of healthy children in most United States environments will throw temper tantrums. In such a circumstance, the acute embarrassment seems rather futile and might well be replaced with an understanding that during the period of negativism children do have temper tantrums, and that this is a step in the development of mature emotional reactions. In our culture, particularly in middle-class culture, it is well known that a high percentage of children between the ages of 2 and 5 will show a great deal of food refusal. Yet there are many mothers and fathers who go through the tortures of the damned trying to get their children to eat food in the amounts they think are necessary during this period. When a reaction such as food refusal is common, it would appear useless to expend so much anxiety about it. Some knowledge on the parents' part not only of the fact that food refusal is all but universal in children during this period but also of the fact that there is probably reduced need for food during this period of slow growth would certainly prevent a great deal of unnecessary anxiety, irritation, and anger.

In adolescence, there is the accelerated maturation of the female as compared to the male, so that the 13-year-old or 14-year-old female seeks her companionship from 16-year-old or 17-year-old males. Many parents worry because they fear their daughters are going to be exploited sexually by these "older men," whereas the girl is actually seeking companionship with people of her own developmental rather than her chronological age. Many junior high schools and high schools are deeply concerned by this problem, which includes such questions as, for example, who shall be invited to school dances, since the taller girls will not dance with the shorter boys of their own age. Such problems interfere with a mutually appreciative relationship between parent and child and generally represent useless anxiety based on ignorance of child development, anxiety that knowledge can relieve. To be sure, knowledge itself is frequently ineffective; it must be transmitted in a setting that allows attitudes to mature and change at the same time that the knowledge is being given.

Cultural Stress.—In our culture many adults face common problems that are also more than necessarily stressful in the absence of knowledge. For example, most women face childbirth with great stress. Yet it is well recognized that the stress of childbirth is much less if the process is understood and prepared for than if the experience comes with no understanding. Although it cannot thus far be statistically demonstrated, it is believed that proper preparation for marriage tends to reduce postmarital adjustment problems. It has been shown that relatively brief and unsophisticated discussion of such problems as fear, reaction to authority, and homesickness can reduce the incidence of psychiatric illnesses and behavior disorders in inductees entering military service. It has not yet been demonstrated but it is widely believed that preparation for retirement, and anticipation and preparation for the use of leisure time coming after retirement, might well prevent the excessive rates of suicides in older men and, perhaps, also the appearance of senile psychosis in people whose retirement has left them with a vacuum in their lives.[8]

The psychiatrist is in a difficult position when he addresses himself to the findings of epidemiology that indicate the high concentration of illnesses in the underprivileged social classes. Here one rapidly approaches the problems of welfare, housing, and public recreation, which are so heavily loaded politically that the physician hesitates to take a stand. The full implications of the World Health Organization definition of health have not yet been worked out. This statement defines health not only as the absence of disease but as physical, mental, and social well-being. In general, medicine is not yet prepared, theoretically or empirically, to deal with these broad, economically tinged problems of social health, nor can one foresee what developments will come as this far-seeing definition begins to affect medical practices more and more. There are certainly germs of ideas for the prevention of psychiatric illnesses coming from these studies. It remains extremely difficult as we presently see "through a glass, darkly" the means of bringing these germs into flowering programs for the prevention of illness.

There is, however, one cultural fact that must indeed give pause. This is the recurring finding that half of the medical and welfare services available to all the community are expended upon a relatively small segment of the population, the now famous "6%."[12] The whole concept of the clustering of diseases of all kinds—psychiatric, physical, and social—in a relatively small group of the population must be considered, for, if some rehabilitation program could be made to succeed for this 6% of the population, we could, in all likelihood, prevent 50% of our social, psychiatric, and physical illnesses. The methods of doing this have not yet been formulated, but they represent one of the most inviting areas for research.

Summary

In considering the prevention of psychiatric illnesses, it must constantly be kept in mind that we are not dealing with a single scheme of prevention but rather with a multitude of illnesses, many of which have specific preventions applicable to them alone. I refer primarily to the mental illnesses secondary to the destruction of central nervous system tissue. On the other hand, there is a large group of psychiatric illnesses that appear to be related to chronic, severe stresses—individual stresses or cultural stresses. It may be possible to reduce individual stresses through education and changing attitudes, particularly in the area of child-parent relationships. There is an approach, not yet fully understood, for the prevention of psychiatric illnesses through the relief of broad cultural stresses playing upon large groups of individuals.

Presently, we are able to work quite exactly in the prevention of brain damage. The relationship between cause and effect is clear and predictable. In the area of the prevention of excessive stress upon the individual, the data are much less exact and the multiple factors have as yet defied final and clear-cut predictability from hypothesized cause to realized illness. It is these two areas, however, where most effective work with present knowledge can be done. We must address ourselves to the future for methods that can be effective in dealing with the third area, the relief of stress playing upon particular groups within the culture—the stresses themselves having their origin, to some extent at least, within the practices of the culture.

EMOTIONAL FACTORS IN GASTROINTESTINAL DISORDERS

Lowell D. Snorf, M.D., Evanston, Ill.

• *Not only functional disorders but also gross organic lesions in the gastrointestinal tract can be caused by emotional stimuli The functional disorders include nervous vomiting, anorexia nervosa, nervous diarrhea, constipation, and irritable colon The disturbances of function may lead to the organic lesions, of which good examples are peptic ulcer and chronic ulcerative colitis A case of the latter is described to exemplify the striking improvement that sometimes follows removal of the patient from a difficult environment. Such problem cases require study and treatment of the total organism and may necessitate consultation between social service department, psychiatrist, and internist.*

I have chosen this opportunity to reemphasize the emotional factors in gastrointestinal disorders This is not a new subject, nor is it a recent concept. Although little evidence can be found in communications prior to this century, it has been well presented in many writings, usually by psychiatrists or strongly oriented psychosomatic internists We who are interested in internal medicine, and especially those of us whose interests lean toward the field of gastrointestinal disease, are grateful to the psychiatrists for their continuous emphasis on the great role that the psyche plays in gastrointestinal disorders. We are often confused by the arguments among the psychiatrists as to the modus operandi of the psychogenesis of these many disorders and disturbed by the dogmatism with which their pronouncements are made.

Such criticisms as inadequate research documentation, or improper controls, leveled at the psychiatrist or the psychosomatist are also applicable to the internist. Indeed, the gastroenterologist has been much too slow to appreciate the common association and interrelation of the personality and these disorders. Physiological research has been dominated by the morbid anatomy concept and not sufficiently integrated with personality and social studies. The most fruitful investigations have been carried out within the last 25 years by students in the fields of physiology, internal medicine, and psychiatry.

These specialists have pooled their studies and theoretical concepts to clarify the relationships of emotional influences to visceral activities Therefore, it would be presumptuous and beyond the scope of this paper to attempt an explanation of various clinical manifestations in which the clinician observes the relationship and strong influence of the psyche on physiological function. All illness must be considered a problem of disturbance of the psyche and soma, the relative influence depending on the dominance of one over the other.

Chairman's address, read before the Section on Gastroenterology and Proctology at the 105th Annual Meeting of the American Medical Association, Chicago, June 13, 1956

The purpose of this discussion is to reemphasize, by way of experience and example, the influence of emotion on the physiological functions of the patient in both health and illness. A trite statement—the abdomen is the sounding board of the emotions—is indeed apropos to our interest. In spite of our general knowledge of this relationship, and its common acceptance, it is surprising how little serious attention is given to this concept in the management of gastrointestinal disorders. No day passes in the activities of an office or hospital practice where problems of a physical nature can be adequately solved without proper evaluation of the psychic impact.

Emotion is commonly referred to in designating ways of feeling and patterns of action. As stated by others, it is a descriptive word representing three aspects: a subjective experience, a type of neurophysiological reaction, and a mode of behavior. The influence of the psyche on physiological behavior has long been recognized but poorly understood. Indeed, most of our concepts today are so closely related to pure speculation that it seems quite improper to take issue with any of them at this level of discussion. We need not argue the presence of psychic factors in illness. Experience and thoughtful observation prove this relationship beyond a doubt. For purposes of discussion, and as a general thesis of an internist, as expressed by Kubie, "psychological forces and somatic manifestations may have their roots in the same unconscious processes which discharge on the level of the psychic representation through thoughts and feeling, and partly on the physiological level through the autonomic nervous system."

Diagnosis and treatment depend much more on history than on other procedures. Careful laboratory studies should be made, to include x-rays, blood studies, stool research, and various metabolic evaluations, so that whatever of organic nature is wrong may be rectified. However, even in the hands of those skilled in these disorders, a personality study may reveal frank irregularities, yet not prove or substantiate them to be primary causes of gastrointestinal trouble.

It is quite impossible to explain adequately the causes of the various disorders of the gastrointestinal tract, in spite of our strong conviction that certain emotional instabilities are frequently present. At present, there are inadequate controls to justify the firm conclusions pronounced by the psychoanalysts; however, until such time as controlled research gives acceptable explanations, we, as internists, must go along, conscious of the emotional impact on the total organism. We must investigate hereditary predisposition, emotional immaturity, repeated psychic trauma, fatigue, frustrations, and fears. It behooves us to record a psychiatric evaluation, even if superficial, in all gastrointestinal disorders. I find it difficult to identify peptic ulcer or chronic ulcerative colitis personalities, yet I would not belittle an attempt to group certain characteristics that, in general, would be suggestive of them. What seems of particular importance is the recognition of certain methodology in dealing with the specific lesions and recognizing the influence of these characteristics on their causes and treatment.

I recall that I first found more adequate explanations for these previously inexplicable manifestations, explanations that emphasized the need for relating organic and functional disorders, in the works of Déjerine and Gauckler, who represented the thinking of the French school of early 1900 and, although lacking the present-day dynamic approach, provided much food for thought. I refer to their interesting presentation on the subject of emotion in gastrointestinal disturbances, because it is one of the early attempts to integrate functional disturbances with a primary organic disease or somatic dysfunction. Slowly this general understanding has become acceptable and is finding its way in the practice of psychosomatic medicine. The revived interest in psychological factors in medical disease is wholesome progress. That a functional disturbance of the stomach or intestine may in time lead to organic disease is a concept that is generally supported in observation and theory. Alexander says, "Anxiety sets in motion different psychological chains, the nature of which is one of the factors determining the type of physiological response that will ensue. Anxiety is not a specific factor in man, but he handles it in a manner characteristic of him."

Peptic Ulcer

Peptic ulcer is an organic disorder exhibiting a close relationship to the emotions. It is a lesion that may occur at almost any age in life. It is commonly found in persons between 15 and 30 years of age, coincident with a time of great instability, a need for understanding and adjustment, when the individual is especially responsive to the undercurrents of stress situations. The importance of psychogenic factors in the etiology of ulcer must be commonly emphasized. Prolonged frustrations, which cannot be adequately resolved, are present frequently in patients with recurrent peptic ulcer.

Physicians are well aware of the inception and exacerbation of ulcer symptoms under stress and fatigue. Increased incidence of acute perforation of peptic ulcer and massive gastric hemorrhage, as recorded by the British during the blitz of World War II, is a well-documented observation. Patients become increasingly conscious, after repeated experiences, that trouble with ulcers begins after bouts of worry or tension rather than after intemperate food indulgence. This would seem to justify the adage that it is not what you eat that causes the ulcer but what is eating you.

Cannon, Pavlov, Carlson, and others were among the first to demonstrate the production of gastric juice of high acid and peptic values through nervous-system stimulation. Minsky, and later Gray, have demonstrated the relationship between varying stresses and uropepsin formation and gastric secretion. The measure of gastric activity in this fashion gives more credence to a theory of relating stress and strain and psychic tensions to physiological manifestations. Wolff and Wolf, with their well-documented evidence, have proved a close relationship between functional disturbances and organic disease and between intense emotional stress and disturbed physiological function. Thus we may accept the proposition that stress from anxiety plays a causal role in the etiology of peptic ulcer. Whether we agree with Draper that "persistent fear and anxiety reaction is the primary emotional reaction" or that the subconscious neurotic conflicts are primary is not pertinent to this discussion. Somehow, an emotional conflict can almost invariably be found as a common denominator.

Individual information must be sought for the overall management of peptic ulcer. This need not be done by a psychiatrist, but by the internist who is willing to give adequate time. The psychosomatist can be more effective in a certain restricted group of patients, but, in the large percentage, the physician who has the patient's confidence and the interest to inquire will most likely succeed in securing information that adequately influences the therapy. Confidence, established at this level and area of management, is an invaluable asset.

Hematemesis and Intractable Ulcers

In other papers I have emphasized the influence of disturbed emotions on acute or recurrent hematemesis and intractable ulcers. When orthodox management incorporates an evaluation of the personality and stress situations of the patient with an ulcer, hemorrhages will be less, the intractable ulcer will occur less often, and surgical indications will cease to be dogmatically stated as "over a certain age, and having had so many hemorrhages." Chronic anxiety may precipitate sudden hemorrhage, and panic and fear have killed many a patient while under observation and treatment for massive hemorrhage. Why harass an exhausted patient in shock by having an inexperienced nurse take a blood pressure every hour? Has anyone instructed the nurse in taking and interpreting a pulse and in offering sound and positive reassurance to the patient? It is understandable that all customary procedures have their place, but to overlook one of the most important techniques—the proper psychological approach—is inexcusable.

Ulcer management includes proper diet, supplemental vitamins, neutralizing medication, and psychological evaluation. To my mind, it would be quite as improper to consider only the stress situations in the patient with ulcers as it would be to confine treatment to diet and antacids. The uncomplicated, relatively acute ulcer may well respond to a fishing trip, but the one complicated with recurrent hemorrhage or moderate obstruction with associated night secretion requires the full therapeutic management. A patient must not only learn to live with the ulcer but, of equal importance, how to live with it. To live with the ulcer implies an understanding of the psychic impact, and failure to anticipate a recurrence necessitates a formula of diet and medicine. Phenobarbital, sodium bromide, and the newer tranquilizing drugs help to control the states of tension that the physician has difficulty in combating. These may be the only means of controlling excessive secretion when the patient is in a highly emotional state.

Chronic Ulcerative Colitis

Chronic ulcerative colitis is another serious disorder in which the psychiatric component in the etiology is preponderant. Some years ago I was asked to see a 16-year-old boy with bloody diarrhea. Proctosigmoidoscopy revealed the characteristic friability of the rectal mucosa, with the minute multiple hemorrhages of chronic ulcerative colitis. The usual supportive measures had been instituted, including numerous transfusions. For the next six weeks there was gradual deterioration, associated anorexia, weight loss, anemia, and pyoderma. Innumerable bloody, watery stools were passed daily. The temperature ranged between 101 and 104 F (33.9 and 40 C), and dehydration became marked. Surgical and psychiatric consultation indicated divergent views. The family would not accept surgery but was willing to try psychotherapy. Fourteen days of local sanatorium supervision resulted in dramatic improvement. The temperature dropped to normal, the stools were reduced from 20 to 2 a day, and the patient began calling for food. His convalescence ran a remarkably smooth course. Hostility and a mother complex were finally clarified. This patient is now 34 years old, a father of two children, a graduate in dentistry, and a teacher in his specialty. He has occasional exacerbations, at which times the intestine is excessively active and the rectal mucosa is friable, returning to a fairly normal state after consultation but without specific medication. It has been my experience that therapy directed toward understanding the personal problems, rather than symptoms of the colon, will return the greatest success.

The patient I have referred to was managed prior to antibiotics and at a time when there were few sulfonamides. Today these drugs are effective in controlling complications. Cortisone and other steroids are used to advantage, particularly in the acute states. These supportive measures are important, but for management and guidance, in the long run, a familiarity with the patient's situational reactions is essential.

Functional Disorders

There are a number of disorders, classed as functional, that alarm the patient, confuse the physician, and, when not correctly managed, result in serious gastrointestinal invalidism. Among the more common may be mentioned nervous vomiting, anorexia nervosa, nervous diarrhea, constipation, and irritable colon. Difficulty in swallowing and unwillingness to eat in young and old patients are frequently observed. Nervous diarrhea, mucous colitis, spastic colitis, and irritable colon are different manifestations of the same basic condition. Family jealousy, parental domination, marital conflicts, family insecurity, fears, and frustrations are commonly associated with these abnormal disturbances.

If organic changes are absent, then the emotional component is the chief etiological factor. Almy has correlated constipation with defensiveness, hostility, courage, and adequacy and diarrhea with dependency, self-reproach, and fear. The stress of having desires frustrated acts on autonomic centers, resulting in disturbances in motility and secretions.

Comment

From the above discussions, might we not assume that consultation between social service department, psychiatrist, and internist should be practiced whenever these difficult problem cases appear? With that attitude in mind, the same philosophy may be expected to dominate the understanding and care of all patients. Briefly then, the examples and references noted above merely serve to emphasize the psychogenesis of gastrointestinal disease. The many classifications of disorders in this system will become unnecessary when there is a fuller appreciation of the constant interrelationship between psychological stress and physical manifestation. Intelligent management considers the human organism as an integrated unit where psychological stress and social maladjustments are given as much consideration as specific therapy to the end-organs.

Conclusions

Emotional stimuli may ultimately lead to a visualized organic lesion such as peptic ulcer or to dysfunction resulting in spasm or uncoordinated peristalsis in the intestine. The facets of psychological origin must be sought for and properly evaluated in treatment. In the field of gastroenterology the greatest success is obtained by study and treatment of the total organism.

636 Church St.

TO SOCIALIZED MEDICINE AND SOCIALISM BY WAY OF THE VETERANS ADMINISTRATION

Louis M. Orr, M.D., Orlando, Fla.

• *The medical program of the Veterans Adminstration shows a steady development from 1917, when the first purely medical benefits for veterans were authorized and limited to veterans with service-connected disabilities, to 1956, when the 170 VA hospitals have more than 123,000 constructed beds and more than 114,000 operating beds as compared with 37,570 patients with service-connected conditions and almost 66,000 with non-service-connected conditions. The course of this wasteful development must lead either to an inequitable situation in which one-third of the adult citizens are, while two-thirds are not, entitled to free hospitalization, or else to government hospital and medical care for the entire population. The unfair discrimination that now operates could be obviated by developing the present plan consistenly to its abhorrent conclusion, namely, complete government control over all personnel and services, with tax-paid, politically controlled medicine for everybody. The reasonable alternative is to reverse this trend as regards the VA program and to protect and improve our private system of health care for all people.*

Those of us concerned over the trend toward socialism in this country, and actively interested in stopping the spread of government control over the nation's medical services, have learned in recent years that we must be on guard against a wide variety of dangers. Some of them are obvious, outright threats, bearing all the earmarks of socialistic thinking. Others, which are more subtle and insidious, require careful study of their future effects and implications. To put it in military terms, we have learned that we must be vigilant not only against frontal assaults but also against flank attacks and infiltration tactics.

An outstanding example of the frontal assault was the attempt in 1949 to push through the Truman-Ewing plan for a system of national compulsory health insurance. The medical profession launched a vigorous campaign against that proposal, took the facts to the people, and mobilized effective, articulate support from an overwhelming majority of the American citizens. Since the failure of the big frontal assault, there have been many examples of the flank attack. These are found in the countless so-called fringe measures that, in effect, would intrude the federal government into medical education, voluntary health insurance, medical care for the dependents of military personnel, construction of private medical facilities, and a wide range of other medical activities, all of which should be left with the states, local communities, and private groups of individuals. These "fringe" proposals, by extending federal control a bit here and a bit there, add up to a tremendous step toward socialization.

It is not enough to be on guard only against new proposals, whether they be obvious or subtle, which would move us in the direction of socialized medicine. There is still another kind of danger that we might call a sort of mental or philosophical subversion of good intentions. This danger arises when a familiar homegrown American program suddenly takes on a new meaning, a new and dangerous significance. We look about us and realize that right here in our own back yard, without any prodding from planners and socializers, we have allowed politicians to create a Trojan horse of ominous dimensions. The best example of this type of danger is the hospital and medical care program of the Veterans Administration. This program, with the passage of time and changing conditions in America, has been allowed to drift far from its original humanitarian purpose. Today, because we as a nation have failed to keep a tight rein on the legislative philosophy behind that program, it now constitutes the biggest single mechanism that could nudge us toward government-controlled, tax-paid medical care for the entire population. To illustrate my point, I should like to quote two brief paragraphs from the 1955 report of the Hoover commission's task force on federal medical services. The task force said in its preface:

> If only because of their increasing number, variety and magnitude, the medical services maintained by the Federal Government call for appraisal of their organization. But the case for critical review is cogent for another reason. Whatever inclines any one Federal medical service to diverge from all others provides thereby a reason for review lest it become first a law unto itself and later beyond any control. The circumstances that favor differences and divergences are many.

Read before the annual meeting of the Louisiana State Medical Association, April, 1956.

> These Federal medical services have come into being at different times during the past 150 years: Thus each has its own history and tradition. They have had different rates of expansion. They have all changed and are still changing, in both reputed and real significance. They have different motives and serve different main purposes.

More than any other federal medical agency, the VA hospital and medical program has become "a law unto itself," a sort of sacred preserve that some people seem to feel should not even be examined or questioned by the American taxpayers who pay the bill. More than any other similar program, it already has gone beyond reasonable control. More than any other, it has changed radically "in both reputed and real significance." Therefore, let us look at the history and growth of the VA program, to see how all this has come about, to appraise the present, and to predict the future. The situation has reached the point where the American people must make a national policy decision affecting not only veterans but the entire population, present and future.

Expansion of Original Program

To begin with, it should be emphasized that the original motive of the veterans' medical care program was the desire to provide care for any veteran who had become disabled in the course of service to his country. That was, and still is, a sound, humanitarian purpose and a legitimate obligation of the federal government. Over the past 33 years, however, as a result of politically motivated acts of Congress, the program has been expanding primarily to provide care for a veteran with a disability that occurred after his discharge from military service and that has no relation to military duty. Emphasis has shifted from the care of service-connected conditions to the care of disabilities that do not originate in military service.

Contrary to some statements and claims, there is no historical precedent or American tradition justifying such a governmental program. The first purely medical benefits for veterans were authorized by the Congress in 1917 in an amendment to the War Risk Insurance Act. The medical services and supplies provided by that legislation were limited to veterans with service-connected disabilities. The Veterans Bureau, superseded by the Veterans Administration in 1930, was created by an act of Congress in 1921, and the following year the new agency took over a number of U. S. Public Health Service hospitals that had been caring for veteran patients.

The first authorization for the care of any kind of non-service-connected cases came in 1923. It occurred then because a reduction in the load of patients with service-connected conditions had made some beds available. As a result, the Congress authorized hospital care for certain veterans of the Spanish-American War, the Philippine Insurrection, and the Boxer Rebellion. The veterans involved were those with neuropsychiatric or tubercular diseases, whether service-connected or not. Although this legislation affected a comparatively small number of veterans, it nevertheless soon required the construction of additional hospital facilities. Since then the ball has been rolling steadily, nudged along by vote-conscious politicians. The door's were opened much wider with the passage of the World War Veterans Act in 1924. This legislation restated the hospitalization provisions of the amended War Risk Insurance Act of 1917. It also provided liberalized hospital privileges, whenever existing government facilities were available, to a veteran of any war, military occupation, or expedition since 1897, regardless of the nature or origin of his disability. By 1926, 17% of all patients in veterans' hospitals were receiving treatment for diseases or injuries not related to military service.

The doors of the veterans' hospitals were swung completely open by the act of July 2, 1926, which eliminated the 1897 date and extended the benefits of the World War Veterans Act to the veterans of any war, military occupation, or expedition. This amendment qualified approximately 5 million veterans for lifetime medical care at public expense. The result was a huge influx of veterans into government institutions and a further acceleration in the construction of hospital facilities not needed for persons with service-connected cases. By 1928, non-service-connected cases were accounting for 49% of the admissions to veterans hospitals, and by 1931, that figure was up to 71%. In 1933 Congress passed a law known as the Economy Act of 1933 that repealed all previous public laws granting hospital or medical treatment or domiciliary care to veterans who served in or after the Spanish-American War. This law and its subsequent amendments provide the basic legislative authority for the current medical program of the Veterans Administration. The most important amendment, relative to non-service-connected disabilities, came in Public Law 141 of 1934, which provided:

> Any veteran of any war who was not dishonorably discharged, suffering from disability, disease or defect, who is in need of hospitalization or domiciliary care, and is unable to defray the necessary expenses therefor (including transportation to and from the Veterans Administration facility) shall be furnished necessary hospitalization or domiciliary care (including transportation) in any Veterans Administration facility, within the limitations existing in such facilities, irrespective of whether the disability, disease or defect was due to service. The statement under oath of the applicant on such form as may be prescribed by the Administrator of Veterans' Affairs shall be accepted as sufficient evidence of inability to defray necessary expenses.

By 1944, veterans' hospital construction had cost 218 million dollars since World War I, and 80% of all admissions during that time had been for treatment of non-service-connected disabilities. In that same year, Gen. Frank T. Hines, then administrator of veterans' affairs, pointed out: "The right of war veterans to hospital treatment for non-service-connected disabilities was initially founded upon the theory that there would be a certain number of vacancies in hospitals acquired and maintained for care and treatment of those having a service-connected injury or disease, and such right has always been conditioned upon available facilities."

For more than 30 years, even in the period immediately after World War II, the VA hospitals have had more than enough beds to care for all persons with service-connected conditions. Nevertheless—and despite the legislative limitation concerning available facilities—the VA hospital system has been continually expanded. What has happened, of course, is simply a constant increase in the number of extra facilities available for non-service-connected cases. This, in effect, distorts the real intent of the basic legislation, not to mention the original purpose of the whole program.

At this point I should like to emphasize four salient facts to help bring this whole problem into better perspective and sharper focus: first, the legislation governing the present VA hospital and medical care program was enacted 22 years ago, when we had less than one-fourth as many veterans as we have today. Second, we now have more than 22 million veterans, living and aging at a time when the nation has been seriously infiltrated by the ideas of the welfare state, and by the philosophy of "let Uncle Sam do it." Third, no legal, binding, ironclad limit has ever been placed on the extent of existing VA facilities, or on the amount of money that Congress can appropriate to build new facilities. And fourth, the facts and philosophy behind the VA program have never been brought clearly to the attention of the American people, who have never given a mandate for the type of operation that has developed.

Cost and Size of VA Program

What has developed? What is the present size and cost of the VA program? This is a problem in which the truth is found in the black and white figures of reports and surveys, so let us look at some of the major facts that emerge from the mass of statistics. In 1936 the VA hospitals had just under 45,000 operating beds. That was already 2,400 more beds than were needed for all persons with service-connected cases in these hospitals on Nov. 30, 1954, 18 years later. At the end of the 1940 fiscal year—and that, mind you, was almost a year and a half before Pearl Harbor—the VA was up to almost 59,000 operating beds, an increase of 14,000 over 1936. The increase alone was greater than the number of patients with non-service-connected conditions in the hospitals at that time. By the end of the 1950 fiscal year, there were more than 106,000 operating beds, but less than 35,000 patients with service-connected conditions. By the end of the 1954 fiscal year, according to the recent Hoover commission report, the VA had 170 hospitals, not including contract hospitals, with more than 123,000 constructed beds and more than 114,000 operating beds. They had at the same time only 37,570 patients with service-connected conditions and almost 66,000 with non-service-connected conditions.

You will note that in less than 20 years there has been an increase of almost 70,000 operating beds that are not needed for patients with service-connected conditions and are used only for those with non-service-connected conditions. The VA program, as presently authorized, is scheduled to reach 174 hospitals with about 126,800 beds, at which point it is supposed to "stabilize." This myth of "stabilization," of course, is the same old story that has been handed out for the past 20 or 30 years by politicians who, in practically the next breath, start asking for more VA hospitals, more beds, and bigger appropriations.

The number of VA hospitals, beds, and patients in those beds on a given day tells only part of the story. The one-day-census method, which the VA prefers and which puts the VA program in the best possible light, proves in itself that the care of persons with non-service-connected disabilities has become the predominant part of the program. However, when we look at the admissions and discharges in VA hospitals in a whole year's time, we get an even clearer picture of what has happened. For example, during the 1934 fiscal year fewer than 64,000 veterans were admitted to VA hospitals and homes. In the 1951 fiscal year the VA treated and discharged over half a million veterans, 512,000 to be exact, and almost 85% of them had non-service-connected disabilities. Seventy-six per cent of those half-million veterans had non-service-connected general medical and surgical disabilities, as distinguished from tuberculosis and neuropsychiatric conditions.

The figures supplied by the VA in June, 1955, and confirmed by VA Administrator Harvey V. Higley, show that persons with non-service-connected cases accounted for over 62% of the patient load on Nov. 30, 1953, and over 61% on Nov. 30, 1954. VA figures also show that in the 1953 calendar year the VA hospitals discharged over 460,000 patients, more than 83% of whom had disabilities not connected with military service. Over 70% of them had been treated for general medical and surgical conditions that had no relation to the time spent in military service. And what about the increase in the cost of the VA hospital and medical program? In 1934 it cost just over 37 million dollars, while in the 1955 fiscal year it cost over 750 million dollars. The VA budget for the 1956 fiscal year is 790 million dollars, not including hospital construction.

I want to underline three basic facts brought out by these statistics. During the past 20 years, the number of VA hospital beds almost tripled; the number of patients treated each year has increased from seven to eight times; and the annual cost of the program has increased more than 20 times over and is fast approaching the 1 billion dollar mark. I ask you, how big must a federal medical program get before it is considered "beyond control" and of "changing significance" and before the American people put a bridle on its size, cost, and philosophy of operation?

Many people in this country, both veterans and nonveterans, believe that the VA program already is too big, and that the time for action is now. Two groups in particular—the American Medical Association and the Hoover commission's task force on federal medical services—have made careful studies of the problem and have developed specific recommendations. Before I discuss the current trends and probable future growth of the VA program, let me outline the findings of those two groups.

A. M. A. Policy

The policy of the American Medical Association is expressed in the committee report adopted by the A. M. A. House of Delegates in June, 1953.

> Your Committee recommends with respect to the provision of medical care and hospitalization benefits for veterans in Veterans Administration and other federal hospitals that new legislation be enacted limiting such care to the following two categories: (a) Veterans with peacetime or wartime service whose disabilities or diseases are service-incurred or aggravated; and (b) Within the limits of existing facilities to veterans with wartime service suffering from tuberculosis or psychiatric or neurological disorders of non-service-connected origin, who are unable to defray the expenses of necessary hospitalization.

> Your Committee recommends that the provision of medical care and hospitalization in Veterans Administration hospitals for the remaining groups of veterans with non-service-connected disabilities be discontinued and that the responsibility for the care of such veterans revert to the individual and the community, where it rightfully belongs

I cannot emphasize too strongly that there has been no change in A. M. A. policy regarding patients with service-connected disabilities. The best possible care for these veterans is clearly a national responsibility. The A. M. A. policy statement said on that point, "Your Committee would like to stress the fact that these recommendations do not suggest any limitation or impairment of the hospitalization or medical care now available to veterans who have become physically handicapped as a result of military service. We are in complete accord with that program."

On the second point, the care of war veterans unable to pay for the treatment of non-service-connected tuberculosis or neuropsychiatric disorders, the A. M. A. policy statement said:

> The recommendation of the Committee with respect to the treatment of veterans with tuberculosis and neuropsychiatric disorders of non-service origin in federal hospitals is believed necessary at this time because of the inadequacy of local facilities designed to provide treatment for all such cases It is the feeling of the Committee, however, that the entire question of whether the care of these patients is a local or a federal responsibility must be reanalyzed by the Congress. The rapidly expanding veteran population and the need for facilities for the remainder of our citizens afflicted with these diseases suggests that community facilities must be developed under state or local administration for the benefit of all. Preferential treatment for veterans with these non-service-connected disabilities cannot be continued indefinitely, in view of its detrimental effect on the health and the economy of the entire nation

The remaining groups of non-service-connected cases, which the A. M. A. believes should now become the responsibility of the veteran himself or his community, are the general medical and surgical conditions, whether they be chronic or nonchronic. These, if you remember, accounted for 76% of all the VA hospital discharges in the 1951 fiscal year, and over 70% of all the discharges in the 1953 calendar year. I can best sum up the A. M. A. position with one more excerpt from the official policy statement:

> The medical profession must concern itself, not with the number of chiselers in Veterans Administration hospitals nor with the efficacy of the Veterans Administration in the administration of enabling legislation, but rather with the broad question of whether such legislation is sound, whether the federal government should continue to engage in a gigantic medical care program in competition with private medical institutions, and whether the ever increasing cost of such a program is a proper burden to impose on the taxpayers of the country. A consideration of this problem must of course be predicated upon a concern for the health of the entire population and not just a particular segment

Hoover Commission Recommendations

The soundness of the A M. A. position was borne out by the 1955 report of the Hoover commission's task force on federal medical services. That report pointed out that of the 21 million veterans in the United States, only 3,500,000 had some service-connected disability; the remaining 17,500,000 had no such disabilities. The task force also estimated that the total number of veterans eligible for war-service benefits would reach a peak of about 24 million in the next three years. In a report containing many facts and figures that demonstrated the uncontrolled expansion of the VA program, the task force had this to say:

> The Veterans' Administration needs a firm legal basis for determining the eligibility of veterans for medical care. The Federal Government has an obligation to care for veterans who have incurred disabilities in service For such veterans, this obligation is of a continuing nature and requires the highest obtainable quality of medical services. But responsibility for the care of veterans with non-service-connected disabilities is not of the same order. Lifelong care should not evolve alone from the very normal incident of fulfilling the duties required of every citizen

The task force recommended that "all existing rules, regulations, executive orders, and laws relating to veterans or veterans' benefits, and in particular to medical treatment and domiciliary care benefits, be consolidated and enacted into a single, all inclusive, comprehensive code." It also recommended that Congress enact legislation to provide that veterans may receive "(a) hospital care for non-service-connected disabilities if medical need for such disabilities was established within three years after separation from service, and (b) outpatient care following hospitalization for those non-service-connected disabilities for which medical need was established at the time the veteran was hospitalized."

The task force estimated that the three-year time limit on establishing eligibility for the care of non-service-connected conditions would immediately reduce the federal government's responsibility from a potential of 21 million veterans to about 7 million, including 3,500,000 with service-connected disabilities The suggestion for outpatient care, if applied within the framework of the three-year time limit, would help to reduce the length of hospital stay, decrease the cost of care, and permit more efficient use of existing facilities Strangely enough, the Hoover commission accepted the task force recommendation on outpatient care, but it did not adopt the proposal for a three-year time limit on establishing eligibility. This, in effect, would open the doors for lifelong outpatient care of non-service-connected disabilities, and would skyrocket the costs of the VA program. It is still a mystery of logic how the parent commission, whose purpose is to save money for the taxpayers, ever arrived at such a paradoxical conclusion

The medical task force also recommended "that Congress authorize no further construction of Veterans' Administration hospitals, and that the Veterans' Administration close and dispose by sale or otherwise any hospital which, in its judgment, can no longer be operated effectively or economically." The Hoover commission accepted those recommendations, and it also recommended that the veteran's statement of his inability to pay for hospitalization should be subject to verification This, of course, is only a halfway measure that does not come to grips with the basic philosophy of the current legislation. Both the task force and the parent commission made additional technical recommendations designed to tighten the administration of the VA program, improve its efficiency, and reduce its cost.

Inefficiency in VA System

There are countless examples of inefficiency, waste, and duplication in the VA hospital construction program and in the over-all operation of the VA system. As just two examples, I want to cite briefly the main facts emerging from two recent surveys in different parts of the country. One concerns the "Home Town" care program that is in operation in some states. Under this type of plan, veterans with service-connected disabilities can obtain outpatient care from private physicians at federal expense. In California, according to a study by the California Physicians Service, a monthly average of 12,000 such veterans get outpatient care from California Physicians Service physicians, and 7,400 get it in VA clinics. Using the San Francisco-Oakland Regional Office VA clinic as a basis, the figures for the 1954 fiscal year show that the average monthly cost was $23.15 for the veterans treated in the VA clinic, as against only $15.40 for the veterans receiving care from California Physicians Service physicians. The cost for each visit was $11.38 at the VA clinic, as against only $5.90 in the physicians' offices. The survey indicated that "Home Town" care for all California veterans with service-connected conditions could save the VA at least $688,000 every year, not to mention the saving of time and money for the patients themselves.

The second survey, by the Cincinnati branch of the National Medical Veterans Society, concerns VA hospital construction policy in that Ohio city. According o this survey, two VA hospitals already serving the incinnati area have 632 beds authorized for general medical and surgical cases but not in use. Even excluding these, there is no shortage of general beds in he area. However, the VA does have an acute need or more neuropsychiatric beds in that area, and Cincinnati could staff such a hospital. Yet the VA is determined to open the Cincinnati VA hospital as a general medical and surgical facility, which will not meet the actual needs of the veterans and will aggravate health personnel shortages already existing in the area.

Regardless of all the statistics indicating waste and extravagance, these are only symptoms of the underlying trouble. The real question involves the basic egislative philosophy behind the program. The VA has to administer its hospital and medical program in accordance with existing laws and the financial directives of Congress. And regardless of whether one agrees specifically with the policy of the American edical Association, or the recommendations of the oover commission or its medical task force, the fact remains that there is mounting concern in this country over the implications of the VA program. That concern is predicated not only upon the gigantic size of the present program but also upon current trends pointing to even greater future growth.

More Expansion Possible

One of the most important single factors is the aging of our veteran population. By 1970—only 14 years from now—the VA estimates more than 86% of the living veterans discharged before June, 1950, will be 45 years of age or older, as compared with a fraction under 23% in 1952. In actual numbers there will be almost 14 million at or beyond age 45, more than three times as many as there were in 1952. At the same time, almost 13% of these pre-Korean-war veterans will be age 65 or over, as compared with only 3% of all veterans in fiscal year 1955. That is, there will be over 2 million veterans at or beyond age 65, more than 10 times the number in 1952 and 3 times the number of all over-65 veterans in June, 1955. Past experience of the federal government shows that as veterans grow older, and more vulnerable to chronic ailments, there is a constant increase in the total patient load of VA hospitals, in the proportion of non-service-connected cases, and in the average length of hospital stay. Unless we change our national policy, these factors will produce a tremendous future rise in the size and cost of the VA program.

Such an expansion was predicted in 1945, five years before the Korean conflict, by Gen. Frank T. Hines, then administrator of veterans affairs: "With the numbers involved in this war and with the needs clause retained in the legislation, a peak load requirement of some 400,000 beds by 1975 would seem a fair estimate. With the needs clause removed the number would be measurably increased to the extent that free hospitalization would be afforded by the government for approximately one-third of the adult citizens of the country, which in turn might involve a recurring annual expenditure for such an item alone of approximately $1 billion."

More recently, in 1952, the VA department of medicine and surgery prepared a report for the Booz, Allen & Hamilton Company, which was making a management survey of the agency. In that report the VA itself estimated that, if present trends and admission policies continue, the VA by 1975 will need 265,960 hospital beds and 78,500 domiciliary beds to support the anticipated patient load. That is a total of almost 350,000 beds.

In addition to the size and aging of our veteran population, other trends and influences are affecting, or can affect, the future expansion of the VA program. One of these, which was officially condemned by the A. M. A. House of Delegates in June, 1954, is the practice of establishing a "presumption" of service connection for veterans' disabilities by means of legislative action rather than by scientific medical examination. Under this practice, a condition is presumed to be service-connected if it occurs within a certain length of time after discharge from service; about 30 specific disabilities have already been included. At every recent session of Congress, many such bills have been introduced, and more and more of them became law. This, in effect, is simply an indirect method of increasing the VA load of non-service-connected cases. The end-result of this dangerous trend could well be for Congress to declare all veterans' ailments service-connected and therefore eligible for complete care with no questions asked.

We can reasonably expect in view of past experience that there will be continuing political efforts to broaden the benefits and loosen the eligibility requirements for veterans themselves. We also can expect politically motivated attempts to extend the VA hospital and medical care program to persons other than veterans. In fact, bills already have been introduced in Congress to provide such care for the dependents of veterans, and that would mean additional millions of government beneficiaries. We can expect, if the nation adopts a program of universal military training, that there will be inevitable political pressures to extend VA benefits to those who have completed such training. And, of course, if we have any more "small" wars like Korea or if we should be so unfortunate as to have another global conflict, then our veteran population will again increase rapidly, and the entire problem will be compounded many times over.

Future Course

When and where does the growth stop? When and where are the various trends checked? In my opinion, the time is now, and the job must be done in the halls of Congress, under the impetus of American public opinion.

The Hoover commission pointed out that the federal government already has undertaken responsibility for all or part of the medical care of about 30 million people. From the standpoint of potential beneficiaries, the VA medical program is by far the largest in the federal government, with 21 million beneficiaries now and an estimated 24 million within the next three years. From the standpoint of cost, the VA medical program is second only to that of the Defense Department, and its budget is approaching a figure of 1 billion dollars a year.

Through the VA program, we already have socialized, tax-paid, government-controlled medicine for one-eighth of our population. All they have to do is apply for it and claim that they are unable to pay for their own care. But what one section of the population gets from the federal government, the rest are likely to want in the near future, and there always will be plenty of vote-conscious politicians around to demand it for them. So what is the next step? Government hospital and medical care for the dependents of veterans?—for industrial workers?—for white-collar workers?—for farmers?—for old people?—for everyone with an income under $5,000 a year?—for the entire population? Where does it stop? Remember that in several countries, Germany and Great Britain for example, government medicine started out covering limited segments of the population, and ended up as full-fledged socialized medicine for all.

Through the VA program we are rapidly creating two classes of citizens with respect to hospital and medical care, those who once wore a uniform and those who did not. If we wait too long, and if we choose the wrong way to correct that unfair discrimination, we will be led down all kinds of socialistic byways. Through the VA program and its ever-mounting costs, we are constantly increasing the tax burden on all citizens, including veterans themselves. We can be taxed into socialism as well as legislated into it. Through the VA program we are siphoning off personnel and facilities needed to develop adequate health facilities for all the American people, including the veterans and their families in their home communities. If this trend is allowed to continue, our private system of medicine will suffer increasingly severe shortages, and the pressures will mount for complete government control over all personnel and services, to solve all problems and to simplify the entire system.

We, and I mean all of the American people, must decide soon, before it is too late, what is to be the future course of the VA hospital and medical care program. That decision will determine whether we protect and improve our private system of health care for all people or whether we eventually reach socialized medicine by default.

SURVEY OF ONE HUNDRED CASES OF WHIPLASH INJURY AFTER SETTLEMENT OF LITIGATION

Nicholas Gotten, M.D., Memphis, Tenn.

• *One hundred patients with previously diagnosed cervical neck strain following auto accidents whose litigation on compensation claims had been settled were queried as to their present clinical status. After legal claims for damage were completed, 88% showed recovery, and over half of these had no residual complaints. Many emotional factors, but especially those concerning monetary compensation, greatly confuse proper medical evaluation and appear to be the cause of the wide divergence of professional prognostic opinions relative to this particular injury.*

Some months ago we neurosurgeons practicing in Memphis, Tenn., became increasingly concerned about the poor results in the treatment of the so-called whiplash type of injuries of the neck; we also became more concerned about the medicolegal implications that followed these types of injuries. The methods of treatment seemed relatively ineffective in many instances and were often complicated by a long period of chronic symptoms. In addition, we found that, when a neurological surgeon was called to give a medical opinion incidental to legal settlement of the accident, there was a wide divergence among the surgeons as to the severity of the injury and as to the future prospect of health. The neurosurgeon was often called to give a deposition or go to court for a defendant individual or insurance company and was expected to render an opinion as to the severity of the symptoms, the length of time that symptoms might persist, and further treatment that might be necessary and to give the degree of partial or total disability.

From the Department of Neurology, University of Tennessee.

Read before the Section on Nervous and Mental Diseases at the 105th Annual Meeting of the American Medical Association, Chicago, June 14, 1956.

In almost every instance another neurosurgeon, one of our colleagues, had also been called to testify for the plaintiff and to render opinions about the same condition, but to his consternation there seemed to be a wide divergence of opinion as to the important factors—again, namely, the type of treatment necessary, the length of time treatment was needed, the various appliances such as traction or neck braces that were indicated, and the possibility of surgery in the future if symptoms persisted. Psychoneurotic symptoms were so prevalent and seemed to be such a dominant factor in these cases that proper evaluation seemed even impossible and tended to underscore, so to speak, the physicians' difficulty in reaching a degree of unanimity of opinion.

In attempting to evaluate and render an opinion that had some validity, we found no adequate follow-up study in the medical literature that was of help. We decided, therefore, that there was a need for a study of cervical neck strains, or so-called whiplash injuries, but that this should be limited to those cases in which the problem of compensation and litigation had been concluded. In this manner, the psychosomatic symptoms could be more ably evaluated and the true degree of the chronic permanent symptoms and final disability more adequately determined.

Analysis of Symptoms

Most neurosurgeons are aware that cervical neck strains are usually caused by automobile accidents in which an occupant of a car, waiting at a traffic light, has his car struck forcefully from behind or from the side. His body is suddenly thrust in a position of acute flexion, followed by extension of head and with more than one oscillation of the head on the neck. To be exact, a matter of quick deceleration occurs, without time for reflex protective fixation of the cervical muscles. The effect of this rapid deceleration is to cause a stretching of the muscles and ligaments of the neck and possibly some edema, hemorrhage, and even direct rauma to the nerve roots. Indeed, we have one patient in whom x-rays revealed evidence of hemorrhage, as noted by a pharyngeal bulge. In addition, there may occasionally be injury to the intervertebral disk, with narrowing of the foramen, and subsequently it is possible that fibrosis and abnormal motility of the vertebral oints may occur. Granting the severe traumatic possibilities, we observed that in most instances the initial evidence of injury seemed trivial or minor, and, indeed, many times the patient, himself, belittled the njury, saying, "I did not think I was hurt" or "I hought nothing of it." He continued on his way, only to have symptoms develop several hours or even days later. In such instances, where there was little or minor vidence of trauma upon physical examination, chronic, persistent symptoms unresponsive to treatment frequently occurred.

Briefly, the symptoms were usually of a pattern. In the acute stage—at the time of the accident—the sensation of being dazed or bewildered was followed in a few minutes to several hours later by headache and nervousness, with neck soreness and tenderness. With these symptoms there were rather rapidly associated profound emotional reactions such as nervousness, instability, insomnia, and sweating of the hands. Many times the symptoms grew progressively worse over a period of weeks, although this was inconsistent with pathological possibilities. The findings by examination were variable in the acute stage. Often there were no objective disabilities, or there might be muscle spasm, fixation of the head and neck, and straightening of the cervical curve as evidenced by or confirmed by x-ray. However, the fact that the symptoms did not adjust to treatment or that they at times would even get worse, but improved after settlement of claims, cast doubt in our minds on the validity of the symptoms and rendered proper opinion by the physicians next to impossible.

Study and Findings

As a result of these problems in the evaluation of this type of injury, we felt that a thorough study of these cases, subsequent to the settlement of compensation or litigation claims, was indicated. Accordingly, funds were obtained to study this problem, with particular reference to symptomatology of whiplash injuries subsequent to the settlement of legal claims. All nine neurological surgeons doing private practice in Memphis cooperated and submitted cases of patients that were suitable for the study with whiplash types of injuries who had been treated or examined by them. A comprehensive questionnaire regarding symptoms, physical disability, attitude toward settlement of litigation, and symptoms subsequent to settlement of litigation was prepared. A fourth-year medical student was obtained to interview the patients and was given their names without other knowledge of the cases. Two hundred nineteen cases were submitted by the neurological surgeons; the student interrogator was able to have personal interviews with and to complete the questionnaire on 100 patients. The purpose of this paper, therefore, is to summarize, review, and record the results of these findings.

The analysis indicates that, out of 100 patients interviewed after settlement, 54 admitted that they were having no appreciable trouble at the time of the interview. None of these 54 patients had considered any of the symptoms serious enough to warrant a visit to a physician within the previous year, which was from 1 to 26 months after settlement of claims for injury. Thirty-four patients reported some minor discomfort on damp, cloudy days; this was manifested by such minor symptoms as pain on doing unusual exercises or unusual lifting, which might or might not be related to the previous injury. Some patients thought that they might have slightly more frequent headaches than prior to the accident. Patients 60 years of age or more showed a much slower recovery than those in the younger age group, and they felt that they had some mild arthritic symptoms possibly related to the injury; these patients are included in this group of 34 with mild residual symptoms.

In the 88 patients mentioned above, the greatest percentage of recovery was during the first year. Thirty-seven per cent of these patients required or were hospitalized for treatment. Many who had some minor complaints of pain admitted upon questioning that they had not followed medical advice as to medication, exercises, limitation of work, or returning for evaluation. A total of 12 patients, in spite of settlement of claims or litigation, appeared to continue to have enough trouble to be wearing Thomas collars, sleeping in traction, taking physical therapy or heat treatments, and periodically visiting a physician for help. Of these 12 patients, 5 had admitted that they refused to carry out the doctor's instructions as advised, in that they refused to modify their activities, rest or sleep in traction, or take physical therapy. Surgery was performed on only 2 patients out of the 100 interviewed, and they were asymptomatic except for slight limitation of motion of the neck.

Of the above group of 88 patients, 85 had liability claims ranging from simple settlements by insurance companies to law suits filed and appealed to state and supreme courts. Of these 85 patients, 49 were satisfied with the settlement and 36 were not. Of the 49 patients who were satisfied with the settlement of their claim, 29 had no significant symptoms at the time of the interview, 11 had only occasional discomfort, and only 4 were still having trouble enough to sleep in traction or occasionally wear a Thomas collar. Of the 36 patients who were not satisfied with their settlements, 9 were cured or had no subsequent symptoms, 20 complained of minor symptoms, and only 7 were having enough trouble to occasionally sleep in traction or to wear a collar. Of the nine patients who had no recourse to claim, that is, their case was not considered one in which they were entitled to compensation or settlement of a liability claim, six were having no trouble whatsoever, two were having minor complaints, and one had moderately severe symptoms.

Subsequent to settlement of legal claims, only three patients lost as much as six months from work or their usual occupation. This includes one patient who has been disabled three years. Only four other patients lost as much as three months' time; all others either lost no time or only a few days from their usual occupation. This compares to 26% who lost six months' time or more prior to settlement and 15% who lost as much as three months from work prior to settlement, making a comparison of 7% losing as much as three months from work after settlement against 41% prior to settlement of claims. While we recognize the comparison is open to some criticism, one cannot help but deduce that settlement of claim definitely influenced the symptomatology advantageously.

Comment

We were forced by the survey to draw certain definite conclusions in regard to psychosomatic symptoms that had developed in a considerable number of these patients. The interrogator, in his interviews with the patients, came to the conclusion that in some instances there were indications that the injury was being used by the patient as a convenient lever for personal gain, so to speak, though not necessarily on a conscious level. These instances were the forcing of a reluctant spouse to pay for household help or insistence on an air conditioner, a new car, a new house, or a vacation in Florida. After the litigation, some patients divorced and remarried; others bought new homes, redecorated the home, and bought new cars. Such changes indicate the possibility that the illness had been used as a means of implementing psychological or other adjustments that had previously been postponed or that, because of financial difficulties, the patient had not been able to fulfill. Our survey indicated that some patients who complained seemed to have developed through the injury an outlet or excuse for avoiding unpleasant tasks and a means of securing recognition from other members of the family and attention from neighbors, friends, and children. This was not thought by the examiner to be entirely on a conscious level, though it may have been conscious in the early stages. On the other hand, it must be noted that some patients financially were actually worse off, having lost their jobs due to being away from work too long in trying to complete law suits or actually feeling that they could no longer do the same type of work.

The conclusion that we draw from this study of 100 patients whose cases have been to a great extent freed of litigation or compensation claims is that the emotional factor plays an important part in the ability of the physician to obtain a satisfactory result from treatment. There seemed every reason to believe that the personal reaction of the patient to his injury complicated the evaluation of his symptoms, treatment, and recovery. The apprehension, nervous tension, and anxiety that these patients developed subsequent to the injury, as a result of fear for future health and as a result of the litigation, tended to accentuate the formation of a profound post-traumatic neurosis. This profound emotional reaction depended to a great extent upon the personality pattern of the patient, as well as the degree of his physical injury. Once the psychoneurotic symptoms had developed, they persisted for many months and were refractory to treatment, being finally resolved to a great extent by settlement of the litigation. It was for this reason that the evaluation of the history, examination, and permanent disability was at all times confusing and could only be made by such a study as we have concluded.

Summary

Of 100 patients with whiplash type of injuries who were interviewed subsequent to settlement of legal claims for damage, 88% have recovered, 54 with no residual and 34 with minor symptoms not requiring therapy. Twelve per cent continue to have severe symptoms, but only 6% of these are under medical treatment. Surgery was necessary in only two cases and was beneficial in both. Many psychsomatic symptoms developed and were manifested in some way in 85% of the cases. Loss of time for as long as three months occurred in 41% of the cases before settlement of claims but in only 7% subsequent to settlement of claims. The evidence indicates the great difficulty in evaluating whiplash type of injuries due to the complicating factor of monetary compensation.

The following neurosurgeons cooperated in this study: Drs. R. E. Semmes Jr., Francis Murphey, C. D. Hawkes, E. C. Schultz, A. R. Tyrer Jr., R. L. DeSaussure Jr., B. W. Cannon, Robert Raskind, and William Ogle.

This study was supported by a grant to the Department of Neurology from the University of Tennessee School of Medicine.

The survey was performed by John R. McInnis, senior student, University of Tennessee School of Medicine.

MECAMYLAMINE IN TREATMENT OF HYPERTENSIVE DISEASE

OBSERVATIONS ON AN UNUSUAL NEUROMUSCULAR COMPLICATION

Roland E. Schneckloth, M.D., Arthur C. Corcoran, M.D., Harriet P. Dustan, M.D.
and
Irvine H. Page, M.D., Cleveland

• *Mecamylamine hydrochloride blocks conduction through autonomic ganglions and is presumed to be completely absorbed when given by mouth. It was evaluated in the treatment of 35 patients with severe hypertensive disease. The initial dose was 2.5 mg. given once or twice daily by mouth; subsequent doses were increased by 2.5 mg. every two days up to the individual patient's requirement for maintenance as determined by the standing systolic blood pressure and therapeutic response. The average daily maintenance dose for the 18 patients who responded with a significant reduction of the blood pressure was found to be 24 mg. (range 5 to 45 mg.). There were, however, 17 nonresponders. Of the 35, only one tolerated therapeutic doses without side-effects and 6 had to stop taking the drug. The others, though uncomfortable, were able to continue medication, in some instances, up to 12 months. The most frequent complaints were constipation, blurring of vision, xerostomia, and various symptoms of postural hypotension. Seven patients, including 5 from this group of 35, showed signs of an unusual neuromuscular disorder, with anxiety, tremor, and even convulsions, while taking the drug. Mecamylamine is considered to be a useful agent in the treatment of hypertensive disease. Its therapeutic advantage over drugs with similar ganglionic effects is small.*

The usefulness of the hypotensive properties of ganglionic blocking agents in the treatment of severe hypertensive cardiovascular disease has been widely established.[1] The therapeutic success or failure of autonomic ganglionic blocking drugs is dependent not only on the sensitivity of the individual patient to their hypotensive effect but also on the ease of administration and avoidance of untoward side-reactions. Erratic blood pressure responses, irregular absorption, and development of tolerance to readily available ganglionic blocking drugs have stimulated a continuing search for more effective antipressor agents of this sort.

Mecamylamine hydrochloride (3-methylamino-isocamphane hydrochloride) is unusual among ganglionic blocking agents in that it is a secondary amine rather than a quaternary ammonium compound. Further, it is believed to be completely, rather than fractionally, absorbed from the gastrointestinal tract[2]; in contrast to hexamethonium,[3] it appears to distribute in a volume of body fluid substantially larger than the extracellular fluid[4] and to be comparatively slowly and only partially excreted as such. Such a combination of properties should yield an agent that would elicit predictable, prolonged responses to oral doses. This would be advantageous, since erratic depressor responses to orally administered hexamethonium or pentolinium have been ascribed, in part, to variations in the fraction of the drug absorbed from the intestinal tract. These presumptions have been supported by previous clinical studies.[5]

We have observed the effects of mecamylamine in a group of patients with severe hypertensive disease, of whom some had had no prior antihypertensive therapy and others had been treated with potent antipressor drugs. The purpose of this report is to present the results of experience with mecamylamine in terms of the control of the hypertensive process, to offer comparisons with other antihypertensive regimens, and to describe what may be an unusual complication of the use of this drug in patients with advanced hypertensive vascular disease.

Method of Study

The group was composed of 12 women and 23 men, ranging in age from 28 to 62 years; the average age was 49 years. All 35 patients were given mecamylamine for at least one month, 13 received it for an additional 2 to 3 months, 7 for 4 to 8 months, and 3 for 9 to 12 months. Of these, 32 were hospitalized during the initial treatment period of one month or more. All who continued to take the drug for longer periods were seen at frequent intervals as outpatients. Blood pressures were measured four times daily with patients in the supine and standing positions by nurses in the hospital or by the patient or a relative at home.

Thirteen hospitalized patients had received no prior antihypertensive treatment; mecamylamine was not administered to these until weekly averages of blood pressures had been constant for two or more weeks, during which time the status of the patient was evaluated.[6] The majority (21) of the patients were restricting sodium intake to less than 2 gm. daily because of evidence of hypertensive heart disease. The diets were not changed during the study period. Twenty-two patients had received prior antipressor medication; of these one patient had been receiving thiocyanate, 6 reserpine, 5 hydralazine alone or in combination with reserpine, and 10 patients a ganglionic blocking agent (hexamethonium, pentolinium tartrate, or chlorisondamine chloride) alone or in combination with reserpine. Reserpine therapy was usually not discontinued in patients who were receiving it; however, mecamylamine was substituted for either hydralazine or the ganglionic blocking agent being used.

Of the 35 patients, 10 had severe essential hypertension and 10 presented the syndrome of malignant hypertension; 11 had residual essential hypertension with varying degrees of vascular damage, remission of a preexisting malignant phase having been accom-

---

From the Division of Research, the Cleveland Clinic Foundation, and the Frank E. Bunts Educational Institute.

plished by previous treatment; and, in 4 patients with severe hypertensive disease (in 3 of whom the disease was in the malignant phase), the process was secondary to primary renal disease. The severity of the hypertensive disease was scored in terms of a composite severity index that rates from 0 to 4 points the extent of vascular disease in (1) heart, (2) kidney, and (3) brain, on the basis of clinical and laboratory study, as well as (4) the level of diastolic arterial pressure, to a maximum score of 16.[1b] The range of the severity index in the group of patients prior to administration of mecamylamine was 3.0 to 14.0 and the mean 8.4.

Response to treatment was classified according to average supine diastolic blood pressure. If this was maintained at less than 110 mm. Hg the patient was considered a responder and, if not, as a nonresponder. The data will show that 20 (57%) of the patients were considered as responders after one month of therapy and 15 (43%) were nonresponders.. The drug therapy was continued 2 to 12 months in 23 of the initial group of 35 patients; 14 (61%) of these 23 patients were then considered as responders and 9 (39%) were classed as nonresponders. Five patients (cases 36 through 40) not included in the group of 35 were observed during an initial period on mecamylamine therapy alone, after which it was given in combination with hydralazine. An additional two patients (cases 41 and 42) are reported on in detail because they exhibited an unusual complication during treatment with mecamylamine.

Dosage and Administration

The initial dose of mecamylamine was 2.5 mg. given in the morning only, or twice daily in the morning and early evening. A few patients whose tolerance to the drug was very small were able to secure uniform control of their blood pressure by taking one or two daily doses, but in most this was secured only by giving additional doses at noon and/or bedtime. The individual doses were increased by increments of 2.5 mg. each, every two days, according to the standing systolic pressure at the time of scheduled medication. The usual prescription was for the individual's maximum dose to be taken when the standing systolic pressure was more than 140 mm. Hg. A smaller (roughly two-thirds) dose was taken when this pressure was between 140 and 120 mm. Hg, and use of the drug was omitted when it was below 120 mm. Hg. Most of the patients attained a fairly stable level of maintenance dosage in the course of less than two weeks. The average maintenance dose in the whole group (at the end of the study period) was 39 mg. daily and ranged widely from 5 to 180 mg.; among the 18 responders at this time (1 to 12 months), this average was 24 mg. (range 5 to 45 mg.); and, among the 17 nonresponders, the average was 55 mg. (range 5 to 180 mg.).

The greatest fall in blood pressure occurred usually one-half to two hours after oral administration but, at times, was delayed for three or four hours. A significant hypotensive effect often persisted for about 12 hours; in some this interval was only 4 to 6 hours, and, in others, notably those in renal failure, it persisted for 24 hours or more. In general, responses to equal oral and intramuscular doses were approximately the same, allowing for the fluctuations in responsiveness and requirement shown by most patients. The day to day dosage requirement of mecamylamine was often quite variable for the same patient. Some individuals were able to take a fairly constant daily dose, but more showed considerable fluctuation in the amount of drug necessary to maintain a reasonably constant blood pressure level. In general, this range of variation in daily dosage requirement of mecamylamine was comparable to that for other ganglionic blocking drugs for the same patient (table 1).

Results

Administration of Mecamylamine to Previously Untreated Patients.—All of the 13 patients who had not previously been given antihypertensive drugs showed at first a significant fall in supine diastolic blood pressure when given mecamylamine (table 2). One patient (case 11) could not tolerate even minimum supine hypotensive doses of the drug because of fainting and totally disabling postural hypotension. Another patient (case 9), with advanced renal disease, developed bouts of severe diastolic hypertension after six weeks of an inadequate response; her blood pressure levels could not be controlled with daily doses of as much as 180 mg.

*P=pentolinium tartrate; Ch=chlorisondamine chloride; R=reserpine; C_6=hexamethonium. Unless indicated, drugs were given by mouth.

Eight of the 13 patients have maintained an average supine diastolic blood pressure of 110 mm. Hg or less during therapy for one to six months (average 3.8) and could be classed as satisfactory therapeutic responders. The pretreatment mean severity index of these responders was 9.3. The mean index fell to 5.6 during treatment; the supine diastolic pressure was reduced on the average by 21 mm. Hg (15%) and the standing diastolic on the average by 35 mm. Hg (28%). The average daily dose of the drug was 26 mg. The mean severity index was somewhat higher (10.9) before treatment among nonresponders than responders and was still quite elevated (8.7) when administration of the drug was discontinued. The average fall in supine diastolic pressure in this group was only 13 mm. Hg (9%). The average daily dose of the drug was 65 mg.

Administration of Mecamylamine to Previously Treated Patients.—In terms of its relative effect on supine diastolic pressure, mecamylamine was more effective than the previous antipressor treatments in 13 of 22 patients; it was no more effective in 2 patients and somewhat less effective in 7 (table 3).

Administration of mecamylamine was discontinued after one to two months of trial in five of these patients. In two of these it was ineffective. One (case 32) was a man with advanced cardiovascular and renal damage whose malignant hypertension had been brought under precarious and partial control during a year of treatment with pentolinium; while taking mecamylamine in doses up to 70 mg. daily, he developed bouts of hypertension (with supine diastolic pressures greater than 140 mm. Hg) and, on two occasions, pulmonary edema. The other patient (case 28) showed a significant rise (15 mm. Hg) in average supine diastolic pressure while taking mecamylamine and subsequently responded satisfactorily to a combination of hydralazine and reserpine. Mecamylamine therapy was discontinued in one patient (case 18) who had shown a good therapeutic response, because of intolerable dryness of the mouth, glossitis, and exacerbation of psoriasis. (Another patient, not in this study group, has also shown exacerbation of psoriasis while taking the drug.) One patient (case 29) stopped taking the drug because of a sensation of nervousness and anxiety and another (case 31) because of disabling postural hypotension.

Ten of the 22 patients have maintained an average supine diastolic blood pressure of less than 110 mm. Hg after continued therapy for 1 to 12 months (average 3.9) and are considered satisfactory responders to mecamylamine from the standpoint of the depressor effect of the drug. The pretreatment mean severity index of these responders was 7.1. The mean fell to 5.8 during treatment; the supine diastolic blood pressure was reduced on the average by 15 mm. Hg (13%). The average daily dose of the drug was 22 mg.

Mecamylamine therapy was continued in 12 patients whose average diastolic pressure was 110 mm. Hg or more during 1 to 12 months (average 2.7) of treatment. Only two of these nonresponders developed pressure averages significantly lower (12 and 24 mm. Hg) than they had shown during prior antihypertensive treatment with other ganglionic blocking agents or with

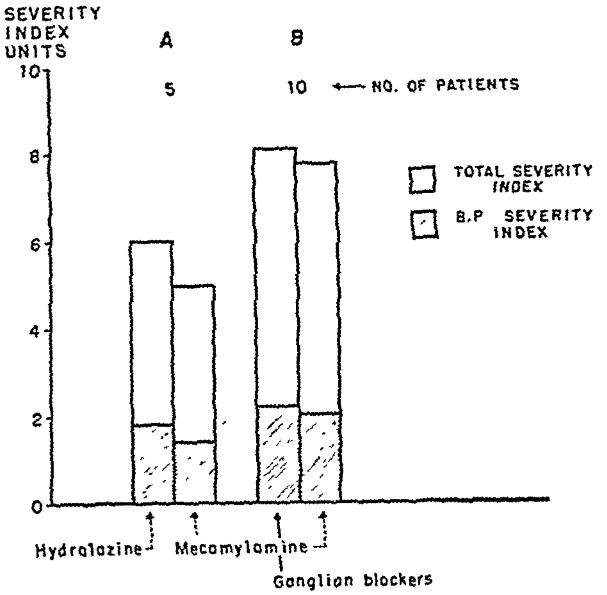
hydralazine. The mean severity index was 7.7 before the substitution of mecamylamine and was nearly the same (7.3) at the end of the study period. The average supine diastolic pressure in this group actually increased 1 mm. Hg (2%). The mean daily dose of the drug was 51 mg.



Changes in total severity index and blood pressure severity units observed in 15 patients with severe hypertension prior to and during one month of treatment with mecamylamine. Group A: prior treatment with hydralazine; group B: prior treatment with ganglionic blocking drugs. Single cross hatching indicates average supine diastolic pressure severity units.

Administration of Mecamylamine with Hydralazine.—Hydralazine (200 to 600 mg. daily) was added to the regimen of five patients (cases 36 through 40) who had been receiving mecamylamine alone for periods of one to two months. Only one patient had shown a good hypotensive response to the drug. The combination was used because the response to mecamylamine was inadequate and/or in the hope of diminishing side-effects by decreasing mecamylamine dosage. Improvement in control was obtained in three patients, in whom supine diastolic pressure was reduced by a mean of 18 mm. Hg, but a large reduction of mecamylamine dosage was possible in only one patient. One patient, who had shown a moderate response to mecamylamine alone, had no further effect from the addition of hydralazine, and the condition of one patient was resistant to both drugs, alone or in combination. The one patient whose mecamylamine dosage was substantially decreased experienced corresponding relief from its side-effects, but in the others the side-effects of hydralazine were merely added to those of mecamylamine.

Comparison of Mecamylamine Therapy with Previous Treatment.—Substitution of mecamylamine for hydralazine in five patients reduced the average supine diastolic pressures significantly in three, caused no appreciable change in one, and increased the average pressure in another (see figure). The over-all severity index in this small group was reduced from 6.0 to 4.9 after treatment for one month. Mecamylamine was substituted for another ganglionic blocking agent (hexamethonium, pentolinium tartrate, or chlorisondamine chloride) in 10 patients. After a month of therapy with mecamylamine, the average supine diastolic pressure in three had been reduced 15 mm. Hg or more (average 17 mm. Hg) below previous levels. The pressure averages remained approximately the same in five and were actually higher in two patients, so that there was no significant change in the average for the group. The total severity index averaged 8.1 before mecamylamine was given and was insignificantly changed (average 7.8) by its use for one month.

The observations do not show that mecamylamine is commonly much more effective in reducing diastolic hypertension than other ganglionic blocking agents. The observed improvement in depressor responses to mecamylamine was attributable more to the vigorous and meticulous control attainable by admitting the patient to the hospital than to the drug as such. All of the 10 patients had taken other ganglionic blocking drugs for a year or more, were skilled and confident in problems of self-medication, and had adjusted to their uncomfortable side-reactions. Five of them noticed little or no appreciable benefits of mecamylamine over the ganglionic blocking agent previously taken. Three patients definitely felt that blood pressure control was smoother and more predictable with mecamylamine and that side-effects, particularly constipation, were somewhat less severe. One patient (case 31) preferred pentolinium, stating that bouts of disabling orthostatic hypotension were less frequent; another patient (case 29) noted apprehension while taking mecamylamine and rejected it in favor of chlorisondamine, which had previously controlled her blood pressure.

Side-Effects

Of 35 patients, only one took mecamylamine in therapeutic doses without significant symptoms due to ganglion blockade. Of the 34 patients who had symptoms, 28 (80%) were uncomfortable but were able to continue the medication, while 6 (17%) were so disabled by side-effects that administration of the drug was discontinued. Symptoms usually persisted throughout the treatment period but were ordinarily either adequately controlled by other measures (bethanechol [Urecholine] chloride, laxatives, leg bandaging) or were finally tolerated without undue complaint. The character and incidence of these symptoms are given in detail in table 4. The severity of the side-effects was

Table 4.—*Severity and Nature of Side-Effects in Thirty-Five Hypertensive Patients Treated with Mecamylamine*

usually directly related to the amount of drug administered; tolerance to the hypotensive effect of mecamylamine with an increase in therapeutically effective dosage was almost invariably followed by an increase in symptoms. The side-effects in general resembled those observed during the use of other ganglionic blocking agents (hexamethonium, pentolinium, and chlorisondamine).

Gastrointestinal symptoms were most common and troublesome. Eighty-six per cent of the patients treated complained of constipation, but these patients responded to regular use of magnesium and/or emodin cathartics. Recurrent nausea and vomiting due to gastric atony occurred in three patients and was a factor in the discontinuance of medication in two of them. Patients were warned of the hazard of paralytic ileus, and this complication has been avoided in all patients by the early recognition and control of incipient intestinal paresis. Dryness of the mouth was commonly observed, occurring in 63% of patients, and was relieved, in part, by orally or sublingually administered bethanechol; dysphagia was a minor complaint of one patient and glossitis a disturbing problem in two.

Uncomfortable pupillary dilatation was noted to some degree by 66% of patients but was of major concern in only one; pilocarpine eye drops often gave some relief. Bladder atony with urinary retention was noted by half the male patients and could be controlled with administration of bethanechol in most, although one patient required transurethral prostatic resection. Impotence was not a frequent complaint in this group of patients, perhaps because sexual patterns had changed during previous therapy with other ganglionic blocking drugs; when directly questioned, all the males acknowledged its presence in some degree.

Disabling postural hypotension was a major factor in the discontinuance of therapy in four patients. Dizziness and faintness on standing was a common complaint in two-thirds of the group but became gradually less troublesome in most patients during the treatment period, responding to elastic bandaging of the legs, to adjustments in amount of drug given and changes in time of administration, and to the patient's learning to adapt to it.

Untoward Neuromuscular Complications

Five of the 35 patients in this study group and 2 others have shown signs of an unusual neuromuscular disorder during treatment with mecamylamine, although the manifestations in one (case 29) were subjective and the association with the drug uncertain. This complication has been manifested by mental symptoms, tremor, and convulsive seizures. These were observed in patients who presented evidences of diffuse, severe vascular disease, so that the abnormalities were at first attributed to cerebrovascular damage. In one patient, the symptoms were suppressed by anticonvulsant drugs, while mecamylamine therapy was continued; in four patients remission of symptoms tended to occur when mecamylamine therapy was discontinued. Similar manifestations had not been observed in patients of comparable physical status under treatment with other drugs, which suggested that this condition was an unusual complication of the use of mecamylamine in patients with severe hypertensive disease. (This conclusion gained support when we were informed by Dr. John R. Beem that like observations had been made by Drs. H. Mitchell Perry and Henry Schroeder at Barnes Hospital, St. Louis, in seven patients with malignant hypertension and uremia.) Relevant observations in our seven patients are tabulated (table 5) and are abstracted below.

Report of Cases

Case 32.—This 53-year-old man was noted above as exhibiting bouts of diastolic hypertension during mecamylamine treatment. These episodes were associated with a persistent state of intense anxiety and restlessness and with the development of a coarse jerking tremor increased by voluntary effort. Slight remission of symptoms occurred when intramuscularly given reserpine was substituted for mecamylamine; however, the patient died from cerebral hemorrhage one week later.

Case 20.—This 40-year-old engineer was given pentolinium and reserpine because of malignant hypertension with renal failure. Substitution of mecamylamine for pentolinium yielded an improved response in blood pressure, but, at the end of a month, he developed a "trembling feeling," for which he was given phenobarbital. Two months later the tremor had increased to the point where the patient was unable to write, and it was noted to be aggravated by emotion. The tremor involved all muscle groups and suggested to the neurological consultant a similarity to chronic (Huntington's) chorea. Symptoms did not subside by discontinuing reserpine therapy. The patient died at home of uremia some months later.

Table 5.—*Neuromuscular Complications Observed During Mecamylamine Therapy*

Case No	Duration Treatment, Mo	Dosage, Av Mg/Day	Blood Urea, Mg/100 Ml	Cerebrovascular Disease, Severity Index*	Presenting Symptoms

29	1.0	44	27	3.0(E)(S)	Anxiety; mild tremor

* S = cerebrovascular accident; E = previous episodes of hypertensive encephalopathy.

Case 4.—This 43-year-old woman had malignant hypertension and was admitted with hypertensive encephalopathy and electrolyte imbalance, controlled by intravenously given sodium nitroprusside[7] and intramuscularly given hexamethonium. Mecamylamine was given for five months, with a favorable hypotensive response. At this time she developed increasing nervousness and depression and, by the sixth month of therapy, rapid, purposeless, irregular movements of the limbs, face, and body, increased by emotion and resembling ordinary (Sydenham's) chorea. Reserpine therapy had no apparent beneficial effect, and, shortly after admission to the hospital, she had two generalized convulsions. She was given diphenylhydantoin and phenobarbital in addition to reserpine and mecamylamine. She promptly improved and, at the end of one month, complained only of occasional jerky movements of the hands and some difficulty in writing.

Case 41.—This 39-year-old woman was admitted with malignant hypertension, mild ecephalopathy, and congestive heart failure, and, as emergency management, was placed on therapy with parenterally given reserpine and pentolinium. The glomerular filtration rate was 22 ml. per minute. A week later, she was given mecamylamine orally; hydralazine was added to the regimen two weeks later. On the fourth week of mecamylamine therapy she complained of "jitters," with involuntary jerking of the hands and arms, four days later, during which time nervousness increased, she had a grand mal seizure, for which she was given sodium phenobarbital intravenously. Subsequent neurological examination showed only a coarse tremor of the hands and tongue, which the neurological consultant could not associate with any known syndrome. Diphenylhydantoin was given, but the tremor increased and was not altered by discontinuing administration of reserpine or hydralazine. Two days after the convulsion, an electroencephalogram showed frequent paroxysms of slow waves and random spikes that were bilateral but not always synchronous on the two sides, the pattern was consistent with a convulsive disorder. An electromyographic record during the fourth week of the disorder indicated electrical silence of the muscle groups studied at rest, but, with voluntary effort, potentials appeared in an increasingly jerky, spasmodic fashion. This pattern was different from the normal sustained rise and also from the rhythmicity of most tremors, the record was suggestive of chorea or other extrapyramidal disease. Therapy with parenterally given pentolinium was substituted for mecamylamine therapy and was continued for three weeks, then discontinued, and small doses of mecamylamine (10 mg daily) were once again given. During the period of pentolinium therapy, the tremor and nervousness gradually diminished, but did not disappear, and increased slightly during two subsequent weeks on mecamylamine therapy.

Case 42.—This 54-year-old man has severe essential hypertension (remission of a former malignant phase having occurred during treatment), hypertensive heart disease, small residues of a recent stroke, and moderate renal failure. Control of the blood pressure with pentolinium and reserpine was only partial, so that administration of these was discontinued. Mecamylamine therapy slightly improved the blood pressure responses. However, three months later the patient complained of anxiety and depression, of insomnia, and of inappropriate and distasteful thoughts and dreams about his family and friends. He was increasingly aware of spontaneous jerking movements of the hands. On his admission to the hospital, an electroencephalogram showed regular, apparently normal rhythms. An electromyogram at rest showed spasmodic bursts of normal motor unit potentials, with long periods of electrical silence between them. With strong voluntary effort, potentials from the motor unit tested occurred as a sustained volley, but background disturbance appeared spasmodically, with intervening periods of electrical silence, the abnormal bursts occurred in no definable rhythm; the pattern was considered suggestive of chorea. One week after mecamylamine therapy was discontinued, the mental changes had all but disappeared and the tremor was greatly relieved. An electromyogram at this time showed sporadic involuntary bursts of potential that were less numerous than before.

Case 23.—This 63-year-old man had had remission of the malignant phase of hypertension, after treatment with hydralazine five years ago, and a state of severe essential hypertension has persisted since that time, with hypertensive renal (azotemia), cardiac and, presumably, cerebrovascular disease. During the past year his blood pressure has been satisfactorily controlled with small doses (10 mg daily average) of mecamylamine. However, at the end of one month of treatment he complained of intermittent dysphagia, which was most severe at the peak of the drug action. This was associated with slurring of speech. In the ninth month, the patient had a grand mal seizure, from which he promptly recovered and which has not recurred. The dysphagia, dysarthria, and the convulsion have been attributed to slowly progressive cerebrovascular damage. However, in the 12th month of treatment with mecamylamine he developed jerking, purposeless movements of the limbs and face, which increased over three weeks to the point where he found it difficult to write or eat. The effects on this of discontinuing mecamylamine therapy are under study.

Case 29.—This woman, aged 52, had severe essential hypertension accompanied by repeated attacks of convulsive hypertensive encephalopathy and, two years previously, by an apparent cerebral thrombosis. Her response to diphenylhydantoin and phenobarbital therapy and to ganglionic blocking agents was unsatisfactory. Urea clearance was about 40% of normal. Nine days after beginning treatment with mecamylamine she had another convulsion. This seizure was indistinguishable from her former convulsive attacks, the last of which had occurred three weeks before. Mecamylamine therapy was continued for another 40 days, during which time she complained of an intolerable feeling of fulness in the head, an indescribable apprehension and anxiety, and a mild tremor of the hands, all of which she associated with the drug. These complaints subsided promptly when chlorisondamine was substituted for mecamylamine, although convulsive attacks have recurred.

Comment

Effectiveness.—The primary aim of ganglion blockade in treatment of hypertensive disease is to effect decrease in arterial pressure, particularly the diastolic, which should be persistent throughout the 24 hours and present in the supine as well as the standing position. The average level of supine diastolic blood pressure is therefore used as the primary criterion of the effectiveness of mecamylamine and other antihypertensive drugs. By the criterion of supine diastolic pressure, accepting a level of less than 110 mm Hg as a satisfactory therapeutic response, mecamylamine orally is effective in about one-half of patients with severe hypertensive disease. All patients who were not receiving other ganglionic blocking drugs responded initially, those taking such drugs showed varying degrees of cross tolerance. Only about one patient in five was found to be, or became, so resistant to the action of mecamylamine as to show no decrease in average diastolic pressure. About one patient in three showed some depressor effect and, usually, temporary remission of signs of rapidly advancing vascular disease, but the level of control was, in general, inadequate. Our experience in this regard corresponds fairly well with that of previous observers, except that our percentages of favorable responses are less, presumably because our criteria of an adequate response are different.

Of greater interest than the absolute effectiveness of mecamylamine is the question of its effectiveness in comparison with similar agents. Mecamylamine had been adequately characterized pharmacologically as a potentially valuable ganglionic blocking agent before it was clinically evaluated. The most obvious distinction of the drug is that effective oral and parenteral doses are nearly the same, whereas those of other ganglionic blocking agents are widely different, the oral-parenteral effective dose ratio often being 10.1. As a result, especially in patients who can be classed as responders to mecamylamine, the average oral daily dose is small. Within limits, it is hardly significant whether a given dose is one of milligrams or grams. If it could be shown that the balance between absorption, excretion, and metabolism of mecamylamine were such that day to day variation in dosage was materially less than for other ganglionic blocking agents, then mecamylamine would have a distinct advantage. This, however, is not our experience. Irregularities in intestinal absorption are not, therefore, major factors in determining the variability of a patient's dosage requirement for a ganglionic blocking agent, since it is assumed that mecamylamine is completely absorbed, and the main determinant is seen to be variations in vascular responsiveness to the drug. Thus, what had been assumed to be a major advantage of mecamylamine is not fulfilled in practice. Nevertheless, some therapeutic advantage of mecamylamine remains, since effective oral and parenteral dosages are approximately equal.

Side-Effects.—The use of mecamylamine would also be clearly advantageous if it could be shown to elicit less of the extravascular effects of ganglion blockade than other agents of this sort. Unfortunately, this is not true. The side-effects correspond in all respects to those of other agents, except that possibly the large volume of distribution and relatively long duration of action of mecamylamine may tend to render some of them less intense during the first hours after taking the prescribed dose.

Neuromuscular Disorder.—The syndrome of jerky involuntary movements of muscle groups, particularly of the hands and arms, which suggested chorea to some observers and which was commonly accompanied by anxiety and also by bizarre mental aberrations in one or possibly two patients, and by convulsive seizures in two others, is described above. All these patients but one (case 29) were, or had been, in the malignant phase of hypertension; two had had strokes before, and one died from cerebral hemorrhage shortly after the syndrome became evident; three patients had experienced hypertensive encephalopathy. Thus, five of the seven patients had sustained hypertensive cerebrovascular damage that may have contributed to their susceptibility to this disorder. The association with renal failure is not as constant; only four of our seven patients showed noteworthy increases in blood urea concentrations, although all showed some evidences of renal damage, with rates of renal blood flow and glomerular filtration rate substantially less than normal. The one patient with a normal blood urea level is also the one (case 29) in whom the relation of the complaints to the drug is least convincing.

The degree of concern that may be attached to this complication is not entirely clear. The usual presenting symptoms of anxiety and tremor should not, at least in their initial phases, be particularly disturbing. However, the advance of these phenomena imposes a real disability, particularly when there are associated major convulsive seizures and disturbing mental changes. Consequently, it would seem advisable that patients taking mecamylamine be observed for involuntary choreiform movements and be questioned as to their psychic state, so that some other agent can be substituted for mecamylamine should such symptoms appear.

No explanation can yet be offered for this complication. The fact that mecamylamine is distributed in more than extracellular fluid volume suggests that it not only may act on the surfaces of the synapses, as do other ganglionic blocking drugs, but may diffuse into nerve cells as well. Indeed, the greater activity of mecamylamine than of other ganglionic blocking agents in inhibiting nicotine-induced convulsions is interpreted as evidence of a direct central nervous system action.[8] Such a localization of the drug might give rise to untoward phenomena, especially in the presence of focal cerebral ischemia and damage. Retrospectively, the syndrome recalled that of lithium intoxication in patients on low-sodium diets,[9] which was also associated with diffuse involuntary movements of skeletal muscle and, in some patients, with mental changes. The lithium syndrome differed, in that there was hyperreflexia and a tendency for fibrillary movements of skeletal muscles, both explained on the direct action of lithium on cell membranes of muscle and nerve. The mecamylamine syndrome is more suggestive of subcortical excitation. In principle, it would seem unlikely that such would be a direct action of the drug itself. Thus, the tremor described in toxicity tests of the drug is more probably attributable to neuromuscular block than to excitation. However, it is recalled that the drug is apparently metabolized in part and that its camphane nucleus may relate some of its possible metabolites to known excitatory agents. The accumulation of such products may be enhanced by renal damage and, in patients sensitized by cerebral vascular damage, might be a basic mechanism in this unusual complication.

Summary

Mecamylamine is a ganglionic blocking drug that has long duration of action and is apparently completely absorbed from the intestinal tract. It was effective in treatment in about one-half of a group of 35 patients with severe hypertensive disease, given average doses of about 25 mg. over periods of 1 to 12 months. In comparison with other ganglionic blocking agents, it is effective in smaller doses, is no more effective in reducing average blood pressure levels, and shows about the same variability of dosage from day to day. Side-effects are also similar, although possibly less intense during the first hours after a single oral dose. The therapeutic advantage is therefore small and lies mainly in the predictability of intestinal absorption.

Neuromuscular disorders were observed in seven patients taking this drug and took the form of anxiety associated with jerky, choreiform movements. Such symptoms may constitute a delayed, unusual toxic effect. Remission occurred in four patients, including one with definite mental aberrations and one who had convulsive seizures, when mecamylamine therapy was discontinued, and one patient responded to the use of anticonvulsive drugs. The symptoms in one patient were primarily subjective, and the association with use of the drug was less definite than in the other six. All these patients had sustained diffuse hypertensive cerebral and/or renal vascular damage, with azotemia present in four and strokes or encephalopathy as evidence of cerebral disease.

The possibility is suggested that some degradation product of mecamylamine may cause central nervous system excitation in such patients. It therefore seems desirable not to prolong the use of large doses of this drug in patients of this type and to observe them carefully for symptoms of this disorder, substituting another ganglionic blocking drug for mecamylamine as occasion arises.

2020 E. 93rd St. (6) (Dr. Schneckloth).

The mecamylamine and bethanechol chloride used in this study were supplied by Merck Sharp & Dohme Research Laboratories, Division of Merck & Co., Inc., West Point, Pa.

EFFECT OF CORTISONE IN ORCHITIS OF EPIDEMIC PAROTITIS (MUMPS)

Capt. George C. Risman (MC), U. S. Army

- *Epididymo-orchitis occurs in about 18 to 35% of cases of mumps. Orally given cortisone was used to treat five patients with this orchitis; 300 mg was administered for the first day, then at least 100 mg. a day for three days or more was used for maintenance, followed by the usual gradual withdrawal period. Significant symptomatic relief, evidenced by less pain and tenderness, occurred within 24 hours, but the duration of the infection and febrile response was apparently not shortened on the initially affected side. The subsequent contralateral orchitis, which occurred in three of the five cases, did appear milder and of shorter duration.*

Epidemic parotitis is a benign self-limited disease that attains clinical significance because of its high incidence and morbidity and the complications that frequently result, such as meningoencephalitis, pancreatitis, orchitis, and mastitis [1] The prophylactic and therapeutic treatment of orchitis and epididymo-orchitis has been the subject of many reports. Among the agents used have been chlortetracycline,[2] chloramphenicol,[3] oxytetracycline,[3a] diethylstilbestrol,[4] streptokinase,[5] convalescence serum,[6] and gamma globulin from pooled mumps convalescence serums.[6b] Except for gamma globulin from pooled mumps convalescence serums, none of these regimens have been generally accepted, nor have they been proved to be efficacious in either the prophylaxis or the treatment of orchitis. Recent reviews have adequately discussed the incidence and pathogenesis of orchitis and summarized the conflicting data of treatment.[7] Recent reports have suggested the efficacy of the steroid hormones in the treatment of orchitis.[8] In five of six cases observed by Solem,[9] the administration of 100 I. U. of corticotropin (ACTH) was thought to have resulted in dramatic relief of symptoms and signs.

This report presents five cases of orchitis secondary to mumps that were treated with cortisone. All five patients were soldiers and were treated in the hospital. Routine laboratory studies, consisting of a complete blood cell count, urinalysis, cardiolipin microflocculation test for syphilis, and roentgenogram of the chest, were within normal limits in all cases All patients were treated with complete bed rest except for bathroom privileges, a diet of choice, scrotal suspensory, and aspirin and barbiturate sedation as needed.

Report of Cases

CASE 1 —A male aged 42 years, was admitted to the hospital with bilateral parotitis of one day's duration Physical examination revealed bilateral parotitis of moderate degree and a temperature of 99 4 F (37.4 C) The serum amylase value was 63 5 mg per 100 cc (Somogyi). On the third hospital day, the patient's temperature rose to 100 F (37.7 C) and he complained of pain in the left testis The testis was swollen to about twice normal size and was dusky red in color and acutely tender. Cortisone was administered orally, 75 mg every six hours for four doses, and then dosage was maintained at 50 mg. every six hours for three additional days, after which the drug was gradually withdrawn (fig. 1). Within 24 hours the pain and swelling were both markedly reduced. On the fifth hospital day the right testis became swollen and patient complained of pain However, these symptoms were much less marked than those noted earlier. Despite marked symptomatic well-being, the patient's temperature spiked daily to 103 F (39 4 C) for four days, and profuse diaphoresis was noted On the ninth hospital day (the seventh day of orchitic symptoms), the temperature fell by crisis and remained normal Testicular swelling gradually subsided after administration of cortisone, but the testes did not return to normal size until the 10th hospital day (8th day after onset of symptoms).

In this case marked improvement in symptoms was noted after the administration of cortisone. An orchitis on the opposite side, however, developed 48 hours after treatment was started. There was no apparent effect on the duration nor on the degree of febrile response, and the resolution of orchitis was not significantly accelerated by cortisone.

CASE 2 —An 18-year-old male was admitted to the hospital with bilateral parotitis of one day's duration. Physical findings were normal except for enlarged parotid glands bilaterally. His temperature was 99 F (37 2 C). The patient's temperature was normal until the fifth hospital day, when it rose to 104 4 F (40 2 C), coincidental with mild swelling and severe pain in the left testis (fig 2). Cortisone was administered orally as follows 75 mg. every six hours for 4 doses, 50 mg. every six hours for 12 doses, and gradual withdrawal in the ensuing three days Within 24 hours there was significant diminution of pain, but little effect was shown on the fluctuating fever (fig 2) No significant effect on the testicular swelling was observed On the eighth hos-

---

From the Medical Service, U S Army Hospital, Fort Jackson, S C

pital day, the right testis became slightly swollen and mildly painful. The signs and symptoms were less marked than those on the opposite side. Complete subsidence of swelling and pain bilaterally was noted on the 11th hospital day.

Considerable improvement of the local signs and symptoms was observed in this case after treatment was started, but complete resolution required six days.

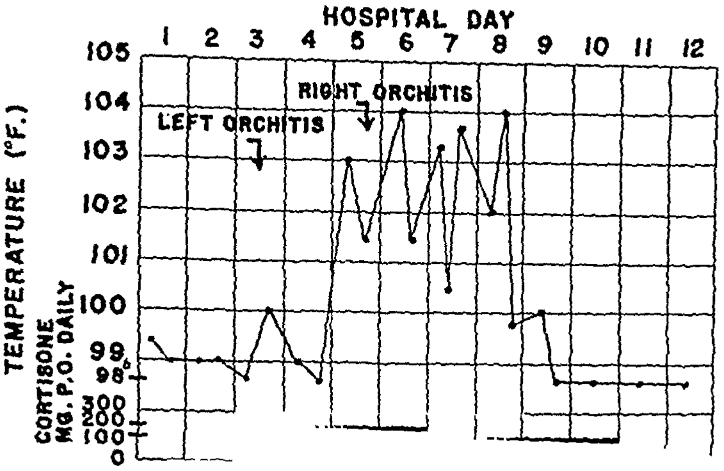

Fig. 1.—Chart of patient in case 1. Note the development of contralateral orchitis during cortisone therapy and the persistence of fever.

The fever was unaffected and persisted for four days. Three days after the onset of therapy, orchitis that was of mild degree developed in the opposite testis and lasted four days.

CASE 3.—A male, aged 20, was admitted to the hospital with parotitis on the right of one day's duration. Physical examination was normal except for finding of enlargement of the right parotid gland to about twice normal size. On the sixth hospital night the patient's temperature rose to 100 F and he complained of pain in the left testis. On the following day the patient's temperature was 102 F (38.8 C) and the testis was enlarged, red, hot, and acutely tender. Cortisone was administered orally as follows: 75 mg. every six hours for four doses, 50 mg. every eight hours for three doses, 75 mg. every eight hours for four days, and gradual withdrawal in the ensuing three days. A mild reduction in swelling and marked decrease in pain were noted in 24 hours. His temperature continued to spike to 102 F daily (fig. 3). On the 10th hospital day the right testis became swollen and painful. At this time the patient was receiving 225 mg. of cortisone daily. The left testis returned to normal size after seven days, while the right testis became free of swelling five days after onset of symptoms.

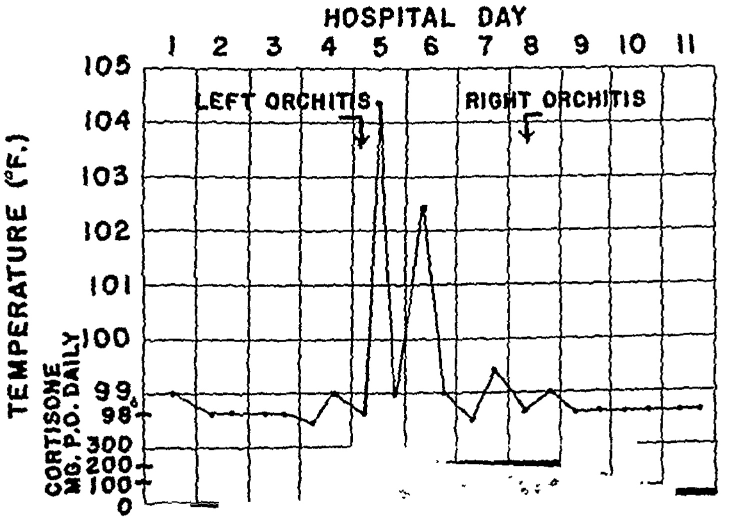

Fig. 2.—Chart of patient in case 2, showing fluctuating course of fever during administration of cortisone.

A significant symptomatic response to cortisone occurred in this case. However, neither the fever nor the testicular swelling was significantly affected. Cortisone did not prevent the appearance of contralateral orchitis but appeared to ameliorate the severity of its symptoms.

CASE 4.—A 21-year-old male was admitted to the hospital with bilateral parotitis of one day's duration. Physical examination was otherwise normal. The patient's temperature was 99.5 F (37.5 C). The serum amylase level was 112 mg. per 100 cc. (Somogyi). A single temperature elevation to 104 F occurred on the second hospital day, but no abnormal findings were noted. On the fifth hospital day his temperature rose to 103.5 F (39.7 C) and bilateral orchitis was noted. Cortisone was administered as follows: 75 mg. every six hours for four doses, 50 mg. every six hours for four doses, and 25 mg. every six hours for the following two days. Symptomatic response was excellent, but persistence of slight testicular swelling was noted bilaterally. On the 10th hospital day, while cortisone was still being administered, the right testis increased in size and became more painful, coincidental with a rise in temperature. Dosage was increased to 75 mg. every six hours. A remission of signs and symptoms was noted on the next day, after which cortisone was gradually withdrawn. Both testes became normal in size on the 12th hospital day, and fever fell by lysis on the 13th day.

The symptomatic response to cortisone in this case was comparable to that in preceding cases. However, a relapse of fever and an increase in testicular swelling and pain occurred while the patient was receiving 100 mg. of cortisone daily. A remission of symptoms appeared to be related to an increase in dosage.

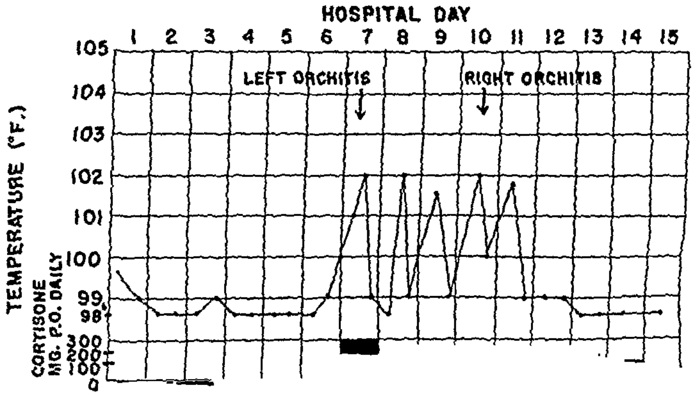

Fig. 3.—Chart of patient in case 3, showing occurrence of contralateral orchitis four days after cortisone therapy was begun.

CASE 5.—A 28-year-old male was admitted to the hospital with known exposure to mumps and parotitis on the left of one day's duration. On physical examination, findings were normal, except for the enlargement of the left parotid gland and a temperature of 99.5 F. On the third hospital day the right parotid gland became enlarged and the patient's temperature rose to 101 F (38.3 C). On the fifth hospital day orchitis developed on the right. Every six hours, 75 mg. of cortisone was given, and this dosage was continued for the next three days (fig. 4). Symptomatic improvement resulted, although no significant resolution of testicular swelling was noted. On the sixth hospital day the testis was more swollen, tense, and turgid but less painful. Fever continued, with daily elevations of the temperature to 103 F, but fell by crisis on the eighth hospital day. The testicular swelling gradually subsided during the ensuing four days. Withdrawal of cortisone was begun on the 8th hospital day and completed on the 12th hospital day. Loss of normal turgor and some softening were noted on the 11th hospital day.

Within 24 hours after cortisone was given, significant, but incomplete, relief of pain was observed in this case. Fever persisted for four days and testicular swelling persisted for six days, despite large doses of the steroid.

Comment

The incidence of epididymo-orchitis as a complication of epidemic parotitis has ranged from 18 to 35% in different series.[10] While testicular atrophy occurs in 35 to 50% of the patients, the occurrence of sterility is thought to be low.[1d] The multiple therapeutic agents used in the treatment of orchitis attest to the failure of any one to be significantly effective. No prophylactic therapy except gamma globulin from mumps convalescence serums has been found effective in reducing the incidence of orchitis.[6b] The administration of estrogenic substances in various doses has not reduced the incidence of orchitis, although Hoyne and co-workers [4a] reported its efficacy. In their report, seven patients given 2 mg. of diethylstilbestrol three times a day did not develop orchitis. However, the small size of the series and the inherent variability of the disease vitiate any conclusions. Other reports[11] including larger number of patients have not confirmed these observations. Therapeutically, however, estrogenic substances have been found to ameliorate the severity of symptoms in many cases.[4] Various antibiotics, such as chlortetracycline and chloramphenicol, have also been used, with dubious and inconsistent results.[12]

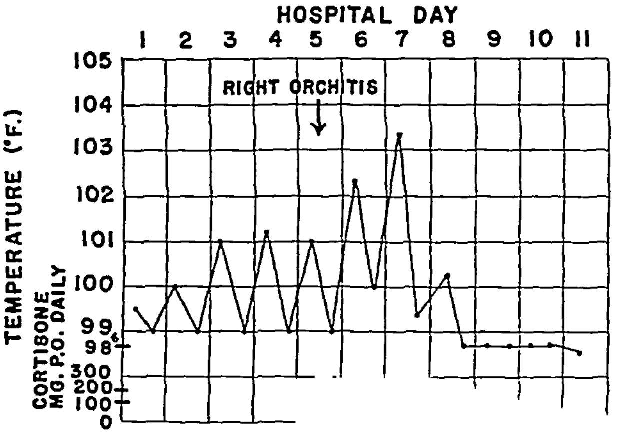

Fig. 4.—Chart of patient in case 5, showing febrile course while on cortisone therapy.

No reports on the prophylactic use of the steroid hormones or the adrenocorticotropic hormone are known to me. However, several statements of their therapeutic effectiveness in symptomatic treatment are available.[8] Solem [9] noted the dramatic subsidence of acute inflammation and swelling within 24 hours after administration of 100 I. U. of adrenocorticotropic hormone in five of six cases. In these instances, however, corticotropin was not administered until the third or fourth day after the onset of orchitis. The possibility of a normal resolution unaffected by therapy occurring four days after onset of symptoms must be considered. In one case a relapse occurred that responded to a second dose of corticotropin on the sixth day.

The use of cortisone in my experience did not afford as salutary or dramatic relief as the previous use of corticotropin had indicated. In the five cases presented, significant, but incomplete, relief was obtained within 24 hours. While the severity of symptoms was markedly reduced, no effect on the duration or degree of fever was noted. The pathogenesis of the infection also was not affected, varying from five to eight days. Three patients developed contralateral orchitis while receiving 100 mg. or more of cortisone daily. In these cases the duration and severity of the contralateral orchitis appeared to be ameliorated. It is apparent that the use of cortisone is indicated only for subjective relief and that it does not affect the course of the disease.

Summary and Conclusions

Five patients with orchitis secondary to epidemic parotitis (mumps) were treated with cortisone. Treatment varied but in all cases was commenced with 300 mg. given orally on the first day symptoms were observed and was maintained with 100 mg. or more daily. Significant amelioration of pain and tenderness occurred within 24 hours, but the duration of swelling was unaffected. Cortisone neither shortened the course of ipsilateral orchitis nor affected the degree of febrile response. Cortisone did not prevent the occurrence of an orchitis on the opposite side, which developed in three patients while they were taking large doses. Symptoms in the contralateral testis were milder, and the duration of inflammation was shorter. No adverse sequelae attributable to cortisone were noted during or following this short-term period of therapy. The course of parotitis did not appear affected by the administration of the hormone. Cortisone can be added to the therapeutic armamentarium for orchitis of epidemic parotitis. Its usage, however, provides only symptomatic relief. All the attendant risks of steroid therapy must be borne in mind during its administration.

INFLUENCE OF HEART DISEASE ON SURGICAL RISK

Jacob B. Dana, M.D.
and
Robert L. Ohler, M.D., Togus, Maine

• *The risk involved in surgical operations on patients with heart disease was studied in 101 patients undergoing 134 operations, and the results were compared with those from a series of 69 surgical patients free from heart disease. The mean ages of the two groups were 61 and 49 years respectively. The gross mortality rates in the two groups were 7.4% and 1.4%, and the rates of incidence of cardiovascular and respiratory complications were 21.6% and 5.6% respectively. The risk for the cardiac patient was therefore greater, but it was not excessive. Patients having an abnormal electrocardiogram as the only cardiac finding and those having hypertensive heart disease or a combination of hypertensive and arteriosclerotic heart disease had no cardiac deaths and suffered no cardiorespiratory complications, but patients with anginal syndrome had a 7% cardiac death rate and a 35% incidence of cardiorespiratory complications. The history is of prime importance in determining the magnitude of the risk, and careful attention to preoperative care, surgical and anesthetic technique, and postoperative care is needed.*

For many years, the impression prevailed among physicians that the presence of organic heart disease increased to a considerable degree the risk in patients undergoing surgery. Within the recent past, several contributions to the medical literature have served to dispel this impression. Proger[1] in 1955 reported on the results in some 500 patients with arteriosclerotic heart disease undergoing major surgery and found a mortality rate of approximately 1%. This compared favorably with the mortality rate in patients without heart disease undergoing comparable surgical procedures. In a more recent review of the problem of surgical risk, Moyer and Key[2] stated that, as more surgical experience is gained with patients having pulmonary or cardiac diseases, these diseases have become less important as determinants of operative risk. Several years ago we undertook this clinical study to help us judge the accuracy of the decisions of the internists in our own hospital regarding operative risk in patients with heart disease. In an aging population such as one finds in a veterans hospital, this is a problem of great magnitude.

Material and Methods

The patients studied were those in our hospital (all male veterans) known to have had heart disease who were subjected to major surgery from January, 1950, through February, 1955. The patients ranged in age from 23 to 85 years, with an average age of 60.9 years. There were 101 patients who underwent a total of 134 operative procedures. In the first 30 days, there were 10 deaths, 3 of them cardiac, and 29 cardiorespiratory complications. The most common surgical procedure in this series was repair of inguinal hernia, carried out 22 times. There were, in addition, 15 transurethral prostatic resections, 14 lumbar sympathectomies, 12 leg amputations, and 8 each of cholecystectomies, suprapubic prostatectomies, and subtotal gastrectomies. The remainder constituted a variety of surgical procedures. Table 1 shows the etiological types of heart disease encountered and the groups in which postoperative deaths occurred. There were 72 patients who had arteriosclerotic heart disease alone or in combination with other etiological types. The majority of the remaining patients had either hypertensive or rheumatic heart disease.

Anesthesia.—The relation of anesthesia to the postoperative mortality and postoperative course is of interest. In this series, spinal anesthetics were used in 68% of the operations. It is considered that the use of spinal anesthesia may have contributed to the death of two patients in this series. A third death was due to laryngospasm occurring during spinal anesthesia. The use of spinal anesthetics in patients with coronary disease has been the subject of a separate study, to be reported elsewhere.[3]

Mortality and Complications

In 134 operative procedures, there were 10 deaths within the first 30 postoperative days, an over-all mortality rate of 7.4%. Three of these deaths were considered to be cardiac, a cardiac death rate of 2.2%. Cardiac deaths followed a cervical sympathectomy, a leg amputation, and exploratory laparotomy. Table 1 shows the types of heart disease from which the patients who died suffered. Brief reports on the patients considered to have suffered cardiac deaths follow:

Case 1.—A 53-year-old male with rheumatic and arteriosclerotic heart disease with aortic stenosis and insufficiency, atrial fibrillation, and a history of congestive heart failure was admitted because of cardiac decompensation. Emergency popliteal embolectomy was followed by gangrene of the involved extremity, requiring a midthigh amputation. Four days after amputation the patient died suddenly and was found to have a posterior myocardial infarction about four days old.

Case 2.—A 71-year-old male who suffered a myocardial infarction six hours preoperatively underwent an exploratory laparotomy for fresh mesenteric artery occlusion. Shortly after induction of spinal anesthesia there was a sudden and precipitous fall in blood pressure, and the patient died within 12 hours. At autopsy there was evidence of recent myocardial infarction.

Case 3.—A 61-year-old male died suddenly three days after cervical sympathectomy carried out for intractable anginal syndrome. An electrocardiogram provided evidence of postoperative posterior myocardial infarction.

From the Veterans Administration Center.

Read before the Ninth Clinical Meeting of the American Medical Association, Boston, Nov. 30, 1955.

Deaths considered noncardiac in this series were due to carcinomatosis, overwhelming infection, bronchogenic carcinoma, electrolyte imbalance, laryngospasm, cerebral vascular accident, and generalized peritonitis.

With all complications occurring during the first 30 postoperative days considered, 84 (63%) of the operations were not followed by complications. Twenty-nine (21.6%) were followed by cardiovascular or respiratory complications and 20 (15%) by surgical complications only. Table 2 lists the cardiovascular and respiratory complications and the complications that were considered to be of surgical origin and unrelated to heart disease. Certain of the patients suffered more than one complication.

"Risk Rate"

As there were in our series only 13 instances of rheumatic heart disease uncomplicated by coronary disease, we have used the figures of Morrison[4] along with our own figures for the two major types of heart disease encountered in this series (table 3). We had 72 patients with arteriosclerotic heart disease alone or in combination with other types undergoing 96 operative procedures, with 10 deaths from all causes, a death rate of 10.4% and a complication rate of 24%. We have used the term "risk rate," coined by Morrison, which is the sum of the death rate and the complication rate. The risk rate in our patients with arteriosclerotic heart disease, including those with conditions having combined etiologies, was 34%. The figures of the hypertensive group are of interest, in that there were 13 patients undergoing 21 operations, with no deaths and no complications.

TABLE 1.—*Etiological Types of Heart Disease*

Rheumatic	4	
Rheumatic and arteriosclerotic	3	
Atrial fibrillation	2	
Pericarditis, constrictive	1	

* Both due to heart disease.
† Due to heart disease.

Controls.—For comparison, a series of 69 consecutive patients without heart disease undergoing similar operations was studied from the point of view of mortality and cardiovascular or respiratory complications. Ages ranged from 29 to 82, averaging 49 years. In this group, there were no cardiac deaths and there was a single noncardiac death (1.4%). There were four cardiovascular or respiratory complications (5.6%): one case each of atelectasis and thrombophlebitis occurring in patients undergoing repair of inguinal hernia, one case of thrombophlebitis in a patient who had undergone a suprapubic prostatectomy, and one pulmonary infarction in a patient who had had a subtotal gastrectomy.

Risk Rate According to Type of Heart Disease.—In an attempt to evaluate the prognostic significance of several of the more common manifestations and etiological types of heart disease, the mortality and complication rates in these groups were studied. It is to be noted that several patients have been included in more than one of the following categories. There were 19 patients with a history of congestive heart failure, all compensated at time of operation, and they underwent 26 operative procedures. The majority of these patients had arteriosclerotic heart disease. No complications followed 18 of the procedures. There was one cardiac death, and there were seven cardiovascular or respiratory complications, which included one case each of coronary insufficiency, myocardial infarction, pulmonary edema, atelectasis, and pneumonia. There were two cases of pulmonary infarction.

TABLE 2.—*Complications Occurring in the First 30 Days After 134 Operations*

operative procedures, and in this group two deaths resulted, both of which were considered to be cardiac deaths. The course of two of the three surviving patients was complicated by coronary insufficiency.

There were 28 patients with a history of anginal syndrome or coronary insufficiency who underwent a total of 37 operative procedures, which resulted in six postoperative deaths, two of which were cardiac. Twenty-three of the operations were not followed by cardiovascular or respiratory complications. There were 13 of these complications in the remaining patients, including one each of pulmonary edema, atrial fibrillation, atelectasis, and postoperative dyspnea of unknown cause. There were, in addition, four myocardial infarctions, two cases of coronary insufficiency, and three cases of pulmonary infarction. There were 10 patients with asymptomatic arteriosclerotic heart disease diagnosed by electrocardiogram only who were subjected to a total of 10 operative procedures. The only death was noncardiac, and there were no cardiovascular or respiratory complications.

Eight patients with arterial hypertension and arteriosclerotic heart disease withstood 11 operative procedures with no mortality and no cardiovascular or respiratory complications. Although this group is too small for these findings to be of statistical significance, it is of interest that Morrison, in a larger group, also found that patients with arteriosclerotic heart disease in combination with hypertension did considerably better than patients with arteriosclerotic heart disease and a normal blood pressure. The significance of these findings is not apparent to us at this time. Six patients with rheumatic and arteriosclerotic heart disease underwent a total of seven operations. There was one cardiac death, and there were three cardiovascular or respiratory complications, which included one case each of myocardial infarction, pulmonary edema, and atelectasis.

Comment

On the basis of this study it is concluded that operative risk in patients with heart disease is not excessive. However, the cardiovascular and respiratory complication rate is considerably higher than in noncardiac patients undergoing comparable surgical procedures. In evaluating cardiac patients for surgery, history is of prime importance in helping to determine whether or not a patient is a good operative risk. The presence of dyspnea or anginal syndrome on exertion and the degree of exertion necessary to produce these symptoms are probably of greater importance than information provided by physical examination or the electrocardiogram. Preoperative preparation of these patients warrants most careful attention. Of particular importance is the correction of anemia and the institution of measures aimed at restoring the status of cardiac compensation. If atrial fibrillation exists, preoperative digitalization aimed at controlling the ventricular rate is certainly indicated.

The best available surgical and anesthetic techniques are required in order that anoxia, shock, and wide fluctuations in blood pressure may be avoided. Fluid requirements should be carefully determined both during and after surgery so that overloading of the circulation, particularly with sodium-containing fluids, is avoided. Results in this study indicate that these patients are especially susceptible to cardiovascular and respiratory complications, the commonest of which are atelectasis, thromboembolic disease, and postoperative coronary insufficiency. Superior nursing care aimed particularly at eliminating the retention of tracheobronchial secretions and the development of venous thrombosis, as well as frequent careful observation by the physician to insure early detection and treatment of this complication, is mandatory. The liberal use of oxygen therapy and bronchodilators may be of great benefit.

Summary

One hundred one cardiac patients underwent 134 major surgical procedures. The gross mortality rate from all causes was 7.4%, and the mortality rate directly attributable to heart disease was 2.2%. The incidence of cardiovascular and respiratory complications was 21.6%. In a control series of noncardiac patients the mortality rate was 1.4% and the cardiorespiratory complication rate 5.6%. The largest group of patients, those with arteriosclerotic heart disease, had a 3% incidence of cardiac deaths and a surprisingly high rate of nonfatal cardiorespiratory complications (24%). Two out of five patients with fresh myocardial infarctions at the time of operation died, and there were two cardiorespiratory complications in the three survivors. Patients with anginal syndrome had a 7% cardiac death rate and a 35% incidence of cardiorespiratory complications. Patients with old myocardial infarctions had no cardiac mortality but a 31% incidence of cardiorespiratory complications. Patients with a history of congestive heart failure had a 3% cardiac death rate and a 27% cardiorespiratory complication rate. Patients having an abnormal electrocardiogram as the only cardiac finding and those having hypertensive heart disease or a combination of hypertensive and arteriosclerotic heart disease had no cardiac deaths and suffered no cardiorespiratory complications. In view of the increased susceptibility of these patients to cardiovascular and respiratory complications, there is a need for the best of preoperative and postoperative care and careful attention to the details of surgical and anesthetic techniques.

Urinary Calculi.—The diagnosis of urinary lithiasis does not end the physician's diagnostic responsibility. It is incumbent upon him to determine if a metabolic disease has contributed to the formation of the stone. . . . A high index of suspicion, plus a systematic investigation by means of a specific history, urine straining, examination of the calculus, roentgenogram of the abdomen, and appropriate blood studies, may be rewarded by the uncovering of a metabolic defect.— R. P. Spencer, Metabolic Diseases and Urinary Calculi, *United States Armed Forces Medical Journal*, August, 1956.

TYPHOID-PARATYPHOID VACCINE WITH CHLORAMPHENICOL IN RECURRENCES OF SALMONELLOSIS

Sister Agnus Therese Simpler, M.D., Sister Maria Corazon Jaramillo, M.D.
and
Sister Gilmary Simmons, M.D., Pusan, Korea

• *Salmonellosis in 86 patients was treated with chloramphenicol and typhoid-paratyphoid vaccine. The chloramphenicol caused the temperature to return to normal generally within four days. The frequency of recurrences depended on the amount of vaccine given. The ratios for recurrence were 1:4 (i. e., 4 out of 16) for patients treated without vaccine, 1:7 in 29 patients treated with less than 1.5 cc. of vaccine, and 1:20 in 41 patients treated with more than 1.5 cc. of vaccine. The combined therapy appeared to be a promising means of reducing the danger of recurrence.*

This is a preliminary report of studies still in progress on the use of typhoid-paratyphoid vaccine administered with chloramphenicol in an attempt to prevent recurrences of Salmonella infections. Due to limited facilities and an overwhelming number of patients, the studies on these cases are not extensive. Furthermore, we have no inpatient service and the home visiting program cannot follow up patients as closely as desired. However, we hope this report may stimulate further studies in centers better equipped to evaluate such work.

Methods and Material

During the three months of October, November, and December, 1955, in our clinic, 74 blood cultures and 377 stool cultures were found to be positive for Salmonella organisms. In addition, there were many reports of Aerobacter that may have been from stools containing Salmonella. In our small laboratory, it is impossible to isolate every colony on a stool culture, and a colony of Aerobacter may be chosen and one of Salmonella organisms left, since they are grossly indistinguishable. Clinically active infection occurred in, and sufficient data are available on, 48 patients with positive blood cultures and 36 with positive stool cultures. We have included also two patients whose culture reports were of Aerobacter but whose clinical indications of infection and Widal agglutination tests gave us no reason to doubt the origin of the infection. This gives a total of 86 patients.

During the early part of the study, blood cultures were made only on those patients whose urine showed a positive Ehrlich diazo reaction. Otherwise a stool culture alone was done. This method has proved unsatisfactory for screening, as some with negative Ehrlich diazo reactions have positive blood cultures and vice versa. At present, we have blood culture, stool culture, and Widal agglutination tests made when the clinical diagnosis is positive.

The mode of administration of chloramphenicol was oral except for an initial parenteral dose in several of the most seriously ill patients. Dosage was 500 mg. every six hours (2 gm. daily), except in a very few patients who received 500 mg. every four hours for the first day or two. The dosage for the children ranged from 30 to 50 mg. per kilogram of body weight for 24 hours. At the same time we gave typhoid-paratyphoid vaccine, 0.1 or 0.2 cc. daily. (Each cubic centimeter of vaccine contained 1 billion Salmonella typhosa organisms, 250 million S. paratyphi A, and 250 million S. paratyphi B.) The chloramphenicol dosage we found satisfactory, as fever had decreased, if it was not absent, by the end of four days, and it seemed to continue to decrease even if the drug was withdrawn. In only one case was it found necessary to give a second course of chloramphenicol because the fever failed to decrease several days after the cessation of therapy. The dosage of typhoid-paratyphoid vaccine, on the other hand, proved to be inadequate. It was therefore increased to 0.3 cc., 0.4 cc., and 0.5 cc. on successive days, and then 0.5 cc. was given three times weekly for at least a month in adults. The patients may have a soreness at the site of injection and a mild rise in fever a few hours after the injection, which may be controlled with the administration of acetylsalicylic acid. In no case was it necessary to stop therapy. The intravenous route was not employed.

Of the 86 patients included in this study, 45 were males and 41 females. The ages ranged from 8 months to 46 years. One patient was under one year of age, 21 were in the first decade, 34 were in the second decade, 9 were in the third decade, and 8 were in the fourth decade. In 23 patients blood cultures were positive for Salmonella typhosa, in 23 for S. choleraesuis, in one for both these organisms, and in one for an as yet unidentified organism of the S. paratyphi C group. Stool cultures on admission showed S. typhosa in 7, S. choleraesuis in 24, S. paratyphi A in 3, and S. typhimurium in 2. As mentioned above, two patients had clinically typical Salmonella infections, with high-titer Widal agglutinations for typhoid in one and for S. choleraesuis in the other, despite a report of only Aerobacter organisms in the stool culture.

Length of time since onset of symptoms varied in the patients with positive stool cultures. Twenty-two were tested in the first week, 11 in the second week, 7 in the third week, 8 in the fourth week, and 2 in the fifth week. No time was recorded for one. There were two patients in whom only the Widal reaction was used for confirmation. The length of time since the onset was two weeks in the patient with a culture showing S. choleraesuis, and in a patient with a culture showing S. typhosa there had been a recurrence.

From the Maryknoll Sisters Clinic.

Results

There were recurrences in 17 patients, of whom 7 gave a history on admission of previous illness, a latent period, and recurrence; while 10 had had recurrences after receiving treatment at our clinic. The length of time from initial onset to recurrence varied from 2 to 11 weeks, while that from the end of treatment with antibiotics to reappearance of symptoms was six days to 6 weeks. However, all recurrences occurred within three weeks, except in one case, in which the recurrence occurred at six weeks. It is possible that this was a new infection with another member of the Salmonella family rather than a real recurrence. Six of the patients who were admitted with recurrences had received no previous antibiotic therapy and had had latent periods of 2 to 10 days, having been back at work or school after long illness when the symptoms reappeared. The other patient with a recurrence had taken chlortetracycline, had been well for a week, and then had relapsed. Of those relapsing after treatment at our clinic, nine were treated with chloramphenicol, one with tetracycline, and one with a combination of these drugs.

As we felt that the therapy with vaccine and antibiotics was of definite value, and since there are many reports on the recurrence rate of Salmonella infections, we soon abandoned the plan of giving vaccine to only alternate patients. Furthermore, with the high incidence of salmonellosis, we did not think it necessary to use only antibiotic therapy when a recurrence might be prevented. In this way we have been able to treat a larger number of patients successfully. We thus decided to continue the study only to ascertain the degree of effectiveness of vaccine, the ideal dosage, and a desirable period of administration.

On these cases, however, we do have a few statistics that seem divergent enough to be of value. In 86 patients treated with antibiotics, we had 10 patients with recurrences while under observation. The recurrences were apparently unrelated to the type of Salmonella infecting, as the types of Salmonella were fairly evenly represented. However, there was an interesting correlation with the vaccine therapy. In 16 cases treated without vaccine, there were four recurrences; in 29 cases treated with less than 1.5 cc. of vaccine, there were four recurrences; and in 41 cases treated with over 1.5 cc. of vaccine, there were two recurrences. One of the two patients in the last group received 1.7 cc. and the other 2.1 cc. of the vaccine. The latter was a 3-year-old child in whom the recurrence was diagnosed clinically only. It may have been another concurrent infection, but the case was included here as possibly one of recurrence despite vaccine therapy. This gives ratios for recurrence of 1:4 in patients treated without vaccine, 1:7 in those given less than 1.5 cc. of vaccine, and 1:20 in those receiving over 1.5 cc. This would seem to prove at least that this work is worthy of further investigation.

The chloramphenicol used in this study was supplied as Chloromycetin by Parke, Davis & Company, Detroit.

CLINICAL NOTES

FATAL URETHAN POISONING AFTER TOPICAL THERAPY WITH URETHAN

Lewis L. Levy, M.D.
and
Tom W. Duke, M.D., West Haven, Conn.

Urethan (ethyl carbamate) has been used as an anesthetic agent in experimental animals for many years. It has the advantage of producing satisfactory anesthesia without respiratory depression. This property has been put to use in obstetrics.[1] Observations of its effect on the hemopoietic system and mitotic cells has led to its use in the treatment of leukemia[2] and other malignant diseases.[3] The cytotoxic action of urethan can be responsible for renal and hepatic damage in addition to bone-marrow depression and sedation. Nausea, vomiting, and anorexia are undesirable side-effects. Reports by Weinstein[4] and Howe.[5] on bacteriostatic action indicate its value in the treatment of wounds and burns. Howe,[6] reporting on the toxic effects of topically applied urethan in 67 patients, found no hematological changes or evidence of liver damage. The amounts used ranged from 30 to 600 cc. of 10% solution daily for 2 to 19 days. One patient received 755 cc. of 10% solution daily for 10 days. In a group of histories added to the original report, he cited a case of a 66-year-old woman who became drowsy, disoriented, and nauseated and who vomited after 200 cc. of 5% solution had been used hourly for 24 hours in bladder irrigations. The symptoms cleared within 24 hours after the drug was withdrawn. Two other instances of anemia and leukopenia, one fatal, the other temporary, were also added to the original report. This case report illustrates the possibility of absorption of fatal amounts of the drug when it is used topically. The initial symptoms were profound general anesthesia and vomiting. Within a few days, bone-marrow depression became evident, and the patient succumbed to massive hemorrhage.

Report of a Case

A 21-year-old male was admitted to the West Haven Veterans Administration hospital on Jan. 11, 1955, for the treatment of burns. Two days prior to his admission he sustained first and second degree burns of the upper extremities, anterior thorax, upper back, neck, and lower face—approximately 30% of the total body surface. Initial treatment at another hospital consisted of intravenous infusion of plasma, whole blood, and fluids. Petrolatum (Vaseline) gauze dressings were applied to the burned areas. Initial laboratory studies showed a peripheral white blood cell count of 12,300 per cubic millimeter, with a normal differential count. His urine contained a trace of albumin, with a few casts and rare white blood cells. During the first 24 hours, his urinary output was 60 to 90 cc. per hour, and his temperature rose to 101.6 F (38.7 C). He received 600,000 units of penicillin twice daily in addition to tetanus toxoid, morphine sulfate, and orally given fluids. On Jan. 10, the day after he re-

ceived the burn, a débridement was done and petrolatum gauze dressings reapplied. The patient was transferred to the West Haven Veterans Administration hospital the next day for more prolonged care.

His medical history and a systemic review were not significant. Examination on Jan. 11, 1955, revealed that dressings covered the described burned parts of a well-developed, well-nourished alert young adult male. His temperature was 101.6 F, his pulse rate was 104 per minute, and his blood pressure was 124/78 mm. Hg. There were 20 respirations per minute. His hair was singed. First and second degree burns were noted on the neck, lips, and alae nasi. The throat was slightly edematous. No other abnormal physical findings were present. Laboratory data on admission were as follows: The white blood cell count was 8,800 per cubic millimeter, with 66% neutrophils, 30% lymphocytes, 3% monocytes, and 1% eosinophils. The specific gravity of the urine was 1.013, and there was 2+ albumin. Microscopic examination of the urine showed 10 to 15 white blood cells per high-power field. Treatment consisted of administration of 300,000 units of aqueous procaine penicillin G twice daily and 0.5 gm. of streptomycin once daily. The patient received a regular diet.

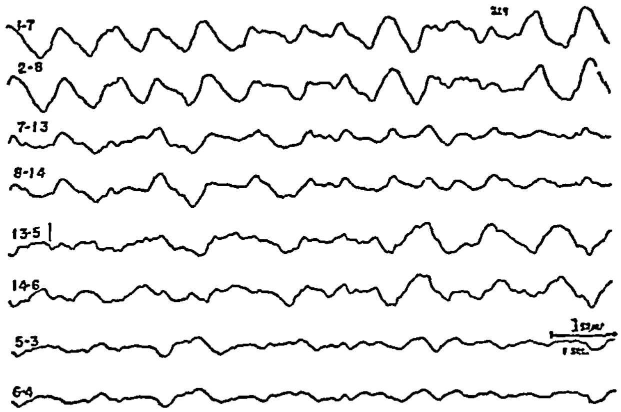

Fig. 1.—Electroencephalogram taken on Jan. 23, one hour after removal of urethan-soaked dressing. Patient was unresponsive. Continuous high-voltage 1 to 2 per second waves seen in all leads. This is consistent with coma. 1-7, left frontal-left anterior temporal; 2-8, right frontal-right anterior temporal; 7-13, left anterior temporal-left posterior temporal; 8-14, right anterior temporal-right posterior temporal; 13-5, left posterior temporal-left occipital; 14-6, right posterior temporal-right occipital; 5-3, left occipital-left parietal; 6-4, right occipital-right parietal.

Hospital Course.—On Jan. 12, 1955, the dressings were changed in the operating room, with the patient under general anesthesia; second degree burns were found on the right upper extremity, with marked edema from the finger tips to the axilla. Second and first degree burns were present on the left forearm and the upper third of the back. There was no edema on the left side. Burned areas were washed with hexachlorophene (pHisoHex) and sterile saline solution, and dry dressings were applied. Although a low-grade fever persisted from the time of admission until Jan. 21, the urine became clear of albumin and white blood cells. The patient was ambulatory on Jan. 13, and he showed no signs of complicating illness. There were no changes in his status until Jan. 18, when dressings were again changed, with the patient under general anesthesia. The dressings were soaked twice daily with a 0.5% solution of acetic acid alternated with 2,000 cc. of a 10% urethan solution with penicillin added. The patient continued his satisfactory course until Jan. 21. He was ambulatory, with good appetite and adequate urine output.

Jan. 21 was the first day of toxic manifestations. Dressings were again changed, with the patient under general anesthesia. During the procedure, the pulse rate increased from 80 to 120 per minute. He remained drowsy for the next 24 hours. The pulse rate varied between 120 and 160 per minute. There was some nausea and vomiting. The administration of antibiotics was continued. Soaking of the dressings with the acetic acid solution was stopped, and the dressings were soaked with the urethan-penicillin solution every three hours. On Jan. 22, lethargy, nausea, and vomiting persisted. The heart rate remained at 160 per minute and the blood pressure was 120/70 mm. Hg. The patient became increasingly sleepy, and his pupils were widely dilated and reacted sluggishly to light. The abdomen was flat and nontender. Peristalsis was audible. On Jan. 23, the patient was areflexic and unresponsive to anything but extreme pain, which made him move but slightly. His condition resembled that of a patient in deep barbiturate narcosis, except that he had a very rapid pulse rate, 160 per minute, and full, deep respirations at a rate of 20 per minute. It was then realized that his symptoms could be the result of a systemic effect of urethan. The urethan-soaked dressings were removed and dry ones applied. He had been bathed with approximately 28,000 cc. of urethan solution containing a total of more than 2,500 gm. of urethan in the interval from Jan. 18 to 23. Laboratory examination revealed that there were 34,400 white blood cells per cubic millimeter, with 96% neutrophils, 3% lymphocytes, and 1% monocytes. The hematocrit value was 46%. There was 27 mEq. of carbon dioxide and 101 mEq. of chloride per liter of serum. The blood urea nitrogen level was 18 mg. and the nonprotein nitrogen level 38.5 mg. per 100 cc. The patient's spinal fluid was normal. An electroencephalogram taken within one hour of the removal of the urethan-soaked dressing showed continuous high-voltage 1 to 2 per second waves in all leads (fig. 1). This was consistent with coma.

On Jan. 24, the patient could be aroused by the calling of his name. He responded accurately to simple questions and was oriented. There was marked nystagmus on lateral gaze to either side. His pupils were widely dilated and did not react to light. Tendon reflexes could not be elicited. In the afternoon, he wakened fully. Later in the day his temperature rose to 104 F (40 C). His white blood cell count was 24,000 per cubic millimeter, with 94% neutrophils, 4% lymphocytes, and 1% monocytes. The hematocrit value was 48%, and the prothrombin time was 25% of normal (Quick method). The blood urea nitrogen level was 63 mg. and the nonprotein nitrogen level 88 mg. per 100 cc. There was 27 mEq. of carbon dioxide and 100 mEq. of chloride per liter of serum. There was 47% excretion of intramuscularly injected phenolsulfonphthalein in two hours. The patient's icteric index was 5.6 units. An electroencephalogram, taken 24 hours after the previous one, with the patient awake, showed that the slow activity was still present (fig. 2).

On Jan. 25, the patient's orientation was less accurate than on the preceding day. He could not cooperate fully during examination. The nystagmus persisted, the conjugate gaze to the right and to the left was incomplete, and the pupils remained widely dilated and fixed. The deep tendon reflexes were barely active. Bilateral Babinski signs were observed. The white blood cell count was 6,000 per cubic millimeter, with 92% neutrophils, 5% lymphocytes, and 3% monocytes. The hematocrit value was 36%, and the prothrombin time was 22% of normal. The blood nonprotein nitrogen level was 81 mg. per 100 cc. There was 30 mEq. of carbon dioxide and 108 mEq. of chloride per liter

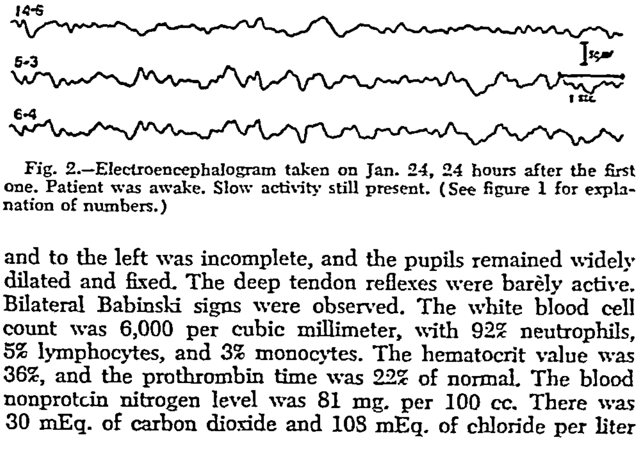

Fig. 2.—Electroencephalogram taken on Jan. 24, 24 hours after the first one. Patient was awake. Slow activity still present. (See figure 1 for explanation of numbers.)

of serum. An electroencephalogram was taken, 24 hours after the previous one, when the mental status of the patient had begun to deteriorate; slow activity was still evident (fig. 3).

On Jan. 26, the patient was disoriented, preoccupied with his discomfort, and difficult to communicate with. Nystagmus was still present, but extraocular movements were full in all directions. The pupils were less dilated. During the afternoon, he became delirious and began to hemorrhage from nose and rectum. Wide areas of ecchymosis developed. An electroencephalogram was taken, 24 hours after the third one, with the patient disorientated; the slow activity had not resolved (fig. 4). On Jan. 27, the patient gradually lapsed into coma. His blood pressure was not obtainable. Hemorrhage was profuse from all body orifices. Vigorous efforts were made to balance blood loss by transfusion, and a total of 2,800 cc. of whole blood was given. Bleeding continued, however, and the patient died at 6 a. m. on Jan. 28, 1955.

Comment

The clinical findings in this case consistent with the previously described systemic effects of urethan were (1) profound anesthesia without depressed respiration, (2) nausea and vomiting, (3) initial increase in the number of white blood cells, with most of them polymorphonuclear, (4) subsequent leukopenia, (5) hemorrhage, (6) renal damage, and (7) hepatic injury. The neurological signs, in addition to anesthesia, attributed to the effects of urethan included nystagmus, disorder of conjugate eye movements, and the Babinski sign. The dilated pupils may have been the result of administration of methantheline (Banthine) bromide for control of nausea and vomiting. The terminal delirium and coma would be expected with hepatic and renal failure.

To our knowledge, the effect of urethan poisoning on the electroencephalogram in man has not been described previously. Observations of electroencephalographic changes during urethan narcosis in rabbits[7] indicated findings similar to those seen in this case: high-voltage ⅓ to 3 per second waves. In a study of anesthetic drugs, French and co-workers[8] noted similar electroencephalographic changes during barbiturate anesthesia, and they postulate the effect of these agents to be on the reticular substance of the brain stem. It is conceivable that urethan has similar action. The presence of nystagmus and the disorder of conjugate eye movement also suggest damage to brain-stem centers. The persistence of slow activity in the electroencephalogram after anesthesia had subsided is interpreted as evidence of diffuse brain damage. This is in keeping with other observations of electroencephalographic changes after brain injury. Nausea and vomiting have been noted when urethan is administered orally, and the symptom is generally thought to be due to local irritation of the gastric mucosa. It seems more likely that this effect is not a local irritation of the stomach but is mediated through central nervous system mechanisms, most likely in the brain stem.

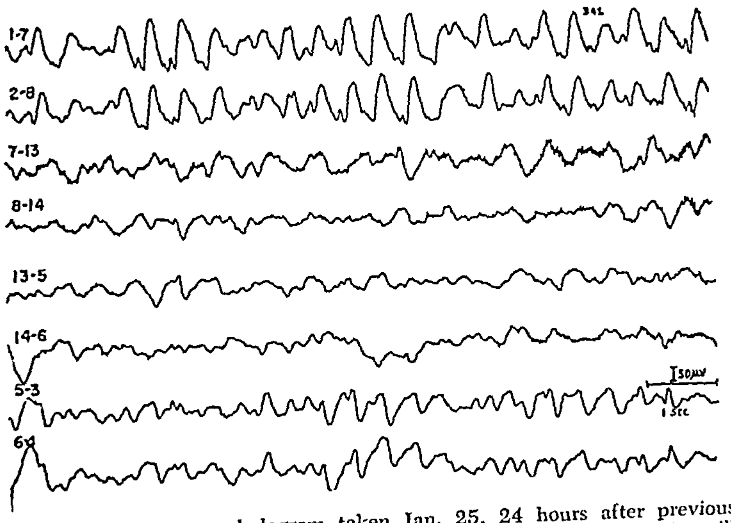

Fig. 3.—Electroencephalogram taken Jan. 25, 24 hours after previous record. Mental status of patient had begun to deteriorate. Slow activity still evident. (See figure 1 for explanation of numbers.)

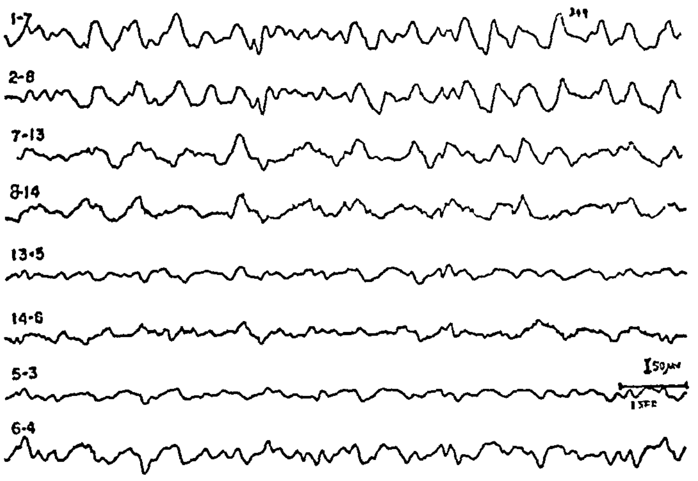

Fig. 4.—Electroencephalogram taken Jan. 26, 24 hours after third examination. Patient was disoriented. Slow activity not resolved. (See figure 1 for explanation of numbers.)

Once absorbed, urethan is rapidly broken down into carbon dioxide, ethanol, and ammonia. Ninety per cent is eliminated through the lungs in 24 hours, and an additional 9% is excreted through the kidneys in a similar period. The remaining 1% is widely distributed in body tissues.[9] The rise in the nonprotein nitrogen level is evidence of renal damage. The elevation of the icteric index and the prolonged prothrombin time signified hepatic injury and bone-marrow depression and were quite evident in this case. With new antibiotics available, topical use of urethan for control of infection should be discouraged.

MENINGOENCEPHALITIS IN INFECTIOUS MONONUCLEOSIS

REPORT OF A CASE TREATED WITH CORTISONE

Capt. Eugene P. Frenkel
Capt. Charles B. Shiver Jr.
Capt. Perry Berg
and
Capt. Timothy N. Caris, (MC), U. S. A. F.

In recent years an ever-increasing number of case reports [1] have directed clinical attention to neurological involvement in infectious mononucleosis. This involvement has been shown to be as diffuse and variable as the classically protean character of the systemic manifestations of the disease. The use of steroids in the treatment of infectious mononucleosis has gained general acceptance since the first description by Doran and Weisberger.[2] Fiese and co-workers [1f] have reported a case of virus encephalomyelitis (Guillain-Barré syndrome) complicating infectious mononucleosis in which there was recovery coincident with the administration of cortisone. A review of the literature fails to reveal any other cases with significant neurological involvement treated in this fashion. The present report deals with a case of diffuse meningoencephalitis in which the patient responded dramatically after the institution of steriod therapy.

A 19-year-old hospital corpsman was well until Aug. 23, 1955, at which time he noted the onset of malaise, lethargy, and insomnia. He was seen in the dispensary, where no abnormal physical findings were noted, and the patient was permitted to rest in quarters. His symptoms abated somewhat with bed rest. However, on Sept. 3, 1955, the patient awoke with a marked exacerbation of his weakness, fatigue, and malaise and developed chills and a fever, with a temperature of 103 F (39.4 C). He had dysphagia and marked anorexia. The patient was hospitalized with a diagnosis of fever of unknown etiology. Upon initial physical examination, the patient had large tender cervical, anterior and posterior, adenopathy; enlarged tonsils covered with a thin purulent exudate; multiple petechial hemorrhages of the soft palate; bilateral axillary and right epitrochlear adenopathy; hepatomegaly; and splenomegaly. Slight stiffness of the neck on passive flexion was noted, but is was felt that this was related to the tender cervical adenopathy. On the basis of the clinical picture, a presumptive diagnosis of infectious mononucleosis was made, and the patient was started on therapy consisting primarily of a diet for hepatitis, vitamin supplements, bed rest, and general supportive care.

On the initial laboratory studies the white blood cell count was 10,200 per cubic millimeter, with 30% polymorphonuclear cells and 70% lymphocytes, of which 10 were of the atypical variety. Liver studies revealed a serum bilirubin level of 0.78 mg. per 100 cc. (with 0.4 mg. per 100 cc. direct and 0.38 mg. indirect), a cephalin flocculation of 2+ at 24 hours and 3+ at 48 hours, and a thymol turbidity of 16.7 units. The initial heterophil titer was 1:56, with a titer of 1:14 on guinea pig absorption and no titer with beef erythrocyte absorption. The remainder of the laboratory studies were entirely within normal limits.

The patient continued to have a persistent fever, with temperatures of 99.8 to 101.8 F (37.7 to 38.8 C) daily, and had progressive systemic symptoms. On the seventh hospital day cortisone therapy was instituted. His temperature rapidly fell to normal, and his systemic symptoms quickly disappeared. The patient did very well and was convalescing without incident except for an episode of epistaxis on the 17th hospital day. Dosage of cortisone was slowly tapered, and therapy discontinued after seven days. On the 19th hospital day the patient again became febrile and malaise and generalized weakness markedly increased. Physical examination at that time was entirely negative. On the following day his temperature rose to 103 F (39.4 C), and he subsequently developed nuchal rigidity. Lumbar puncture at that time revealed an opening pressure of 360 mm. H_2O, clear fluid, and a cell count of 21, all polymorphonuclear cells. The protein level was 61.5 mg. per 100 cc., and the sugar and chloride levels, serology, and colloidal gold curve were all normal. Physical examination revealed an alert well-oriented male. The entire neurological examination was within normal limits. Blood cultures were drawn, and after 12 hours a gram-positive coccus appeared to be growing on one of these. The cerebrospinal fluid was negative on smear and cultures. Although an infectious mononucleosis type of meningoencephalitis was suspected, the one early presumptive positive blood culture led us to treat the patient with large doses of sulfadiazine and penicillin. At this time, the patient had a second episode of epistaxis, which was controlled by packing and vasoconstrictors locally applied. Antimicrobial therapy was continued for seven days without any real abatement in fever, symptoms, or clinical signs. During this period neurological deterioration of the patient was noted. He first became unable to recognize his visitors and then developed generalized muscular twitchings, fine tremor of the tongue, and an intention tremor of the hands. Shortly thereafter a horizontal nystagmus was noted, and his speech became progressively slurred. He became more confused and was disoriented as to time and space. The patient developed progressive generalized muscle weakness and was unable to maintain a sitting posture. The Romberg sign was present, adiadochokinesia was noted, and muscle incoordination and weakness made self-feeding almost impossible. The reflexes were equal; no pathological reflexes were noted. The final laboratory studies revealed that the previously reported coccus in the one blood culture was Micrococcus (Staphylococcus) pyogenes var. albus, and it was considered to be a laboratory contaminant. All other blood cultures (five in number) and the culture of the cerebrospinal fluid were negative.

Therefore, on the 26th hospital day, therapy with both penicillin and sulfadiazine was discontinued, and the patient was started on therapy with cortisone, 300 mg. per day, in keeping with the diagnosis of infectious mononucleosis with associated meningoencephalitis. A repeat lumbar puncture done on this day revealed an initial pressure of 160 mm. H_2O; 47 cells, all lymphocytes; and total protein level of 131 mg. per 100 cc. The sugar and chloride levels, serology, and smear were normal. An interim agglutination test for heterophil antibodies revealed a titer of 1:224, with no absorption by guinea pig kidney and complete absorption by beef erythrocytes. The patient responded very dramatically to cortisone therapy, with lysis of his fever in 36 hours. Within this same period notable clearing of the sensorium occurred, as well as resolution of the nystagmus and tremor of the tongue. By 48 hours the diffuse muscle twitchings were no longer noted and all cerebellar signs were absent. Within 72 hours almost all neurological signs completely cleared. The patient convalesced without further event. A slight residual intention tremor of the hands persisted, as did a slight amount of emotional lability. Both of these symptoms were well controlled with administration of phenobarbital, ½ grain (30 mg.) three times a day. The patient is now completely asymptomatic and has returned to duty.

Comment

In infectious mononucleosis, a perivascular infiltration composed of both normal and abnormal lymphocytes is found in various organs of the body. It is believed that these cells are not invasive, but rather a result of metaplastic changes of reticuloendothelial cells already present in the involved tissues.[3] The perivascular infiltration is not distributed uniformly in the body, and, in a given patient, it may be most pronounced in the liver, kidney, heart, lungs, or the central

---

From the Department of Internal Medicine of the 6022nd United States Air Force Hospital, APO 994, San Francisco.

important factor in this patient's inability to mobilize antibodies to vaccinia was the suppressive effect of cortisone therapy, since her leukemia was under good control and administration of gamma globulin failed to alter the course of the vaccinia infection. The patient also had a herpes simplex infection that conceivably might have disseminated under the cortisone influence, but cultures from the various lesions revealed vaccinia virus. It would seem unwise to introduce live virus into patients with leukemia when they are receiving cortisone therapy, as danger of dissemination of the virus exists.

Summary and Conclusions

A fatal case of generalized vaccinia occurred after vaccination in a patient who was on cortisone therapy for chronic lymphocytic leukemia. The introduction of live viruses into patients receiving cortisone may be unwise, and additional studies in this respect seem indicated.

MEDICINE AT WORK

THE AUTOMOBILE—A CHALLENGE TO MEDICINE

DOCTORS HAVE INTIMATE KNOWLEDGE OF SMASH-UPS. ARE THEY LOGICAL LEADERS IN AUTO SAFETY?

On at least a dozen fronts this month, a problem with the familiarity of a street scene is being attacked as diligently as any group of physicians ever attacked an epidemic. The problem is motor-traffic casualties, and more and more doctors are finding themselves at the crossroads.

For decades, nonmedical experts have seen the tire-writing on the pavement, until now it reads: A traffic death in the United States on the average of every 14 minutes, an injury every 25 seconds. They point to the fact that automobiles have killed 150,000 more people than have lost their lives in all our nation's wars put together. The death toll rises yearly.

Does that constitute a disease? Something of an answer came last June when the House of Delegates of the American Medical Association—viewing it as a medical problem "of major importance" affecting "more persons than does all illness known today"—voted to create a special Committee on Medical Aspects of Automobile Injuries and Deaths. Within a few weeks that committee, under Dr. Fletcher D. Woodward of Charlottesville, Va., will meet to determine how such factors as driver-license standards, motor-vehicle design and equipment, medication to drivers, and improvement of first-aid procedures at accident scenes might be of legitimate interest to the medical profession.

What Is Happening Now

Meanwhile, attack on the nationwide problem includes these other current developments:

—A documentary film, "On Impact," produced jointly by the A.M.A. and the Ford Motor Company, began appearing on television screens across the nation two weeks ago to dramatize prevention of automobile accidents.

—On Oct. 8, the World Medical Association began detailed study of an urgent report from an Australian delegation calling for "consideration of the subject of road accidents."

—Earlier this month, the A.M.A. Women's Auxiliary accented safety-consciousness at a workshop in Chicago, urging that Congress appoint a national body to regulate safety standards in auto construction.

—In the past week, also in Chicago, the National Safety Congress met to consider new ways to fight slaughter on the highways.

—A U. S. House subcommittee is preparing for public hearings in a few months to consider the role medicine might play against the increasing number of traffic deaths.

—Engineers at the Cornell Aeronautical Laboratory are now completing the prototype of an experimental automobile designed to let occupants walk away from a 50-mile-an-hour head-on collision.

—The World Health Organization is putting out a list of some two-dozen suggested conditions that should bar issuance of vehicle licenses to unqualified drivers.

—An intensive investigation of personal and interpersonal factors in motor-vehicle accidents is under way at the University of Colorado and the Fitzsimons Army Hospital. Similar studies still are going on at the Harvard School of Public Health.

—Continuing interest in traffic safety as a medical problem is reflected in the fact that this is the 16th article on auto accidents to appear in The Journal in the past year.

—The U. S. Public Health Service is now expanding its home-safety unit into a new "accident prevention program" covering highway deaths and injuries as well.

—This week, the International Association of Chiefs of Police invited physicians, as either individuals or medical societies, to work with the association in helping to solve the traffic-casualty problem.

—New York State is putting final touches on Governor Harriman's plan for a scientific study of the human factors in traffic accidents.

Chairman Woodward of the new A.M.A. committee points out that, significantly perhaps, there is no coordinated direction in the many-angled fight for highway safety. He says: "Dozens of agencies are investigating, are viewing with alarm, are making surveys and announcing findings, and are trying to correlate.

But so often the result is overlap, duplication and repetition of old facts and theories. There is strong need for leadership." He suggests that physicians may be the logical leaders in any movement toward reduction of traffic casualties because of their biological science background and their intimate knowledge of crash effects and the problems of human behavior that might figure in the smashups.

The medical profession thus is in a position not only to gauge aspects of auto design and to set up physical standards in the reissuance of revoked driver permits but also to guide research and to advise on the many physical conditions that determine whether a patient should drive.

Real Cow and Fake Calf

You might chuckle at the curious plight of Mr. and Mrs. Milo Ewing of Denver several years ago when a 1,300-lb. cow, fleeing from a stockyards, leaped off an overpass and landed kerplunk on the roof of the couple's car as they were driving along. But it is no laughing matter to consider the hallucination of a weary truck driver who told Harvard researchers how he was injured when he "saw" a calf in the roadway. He swerved, overturning the truck. It turned out there was no calf—just a "dream image" common to many people who drive when they are too tired.

Why does a man drive when he is too tired—and what is "too tired?" Why does the motorist speed beyond the capacity of his reflexes—and what is that capacity? Why does he persist in driving while drunk? Why does he react as he does in traffic and to traffic enforcement?

These questions indicate a psychological base to the traffic-safety problem. A survey in 11 northeastern states revealed that drivers are getting progressively more irritable in the squeeze of mounting traffic congestion. Research at Harvard shows that a motorist's attitudes and personal adjustments are more important in driving safety than his physical skill, vision, or reaction time. At the same time, Dr. Leonard Scheele, the former U. S. surgeon general, calls for periodic reassessment of driver health and skills at license renewal time. In one state, South Dakota, presumably you can get a driver's license if you are totally blind; there are no visual requirements.

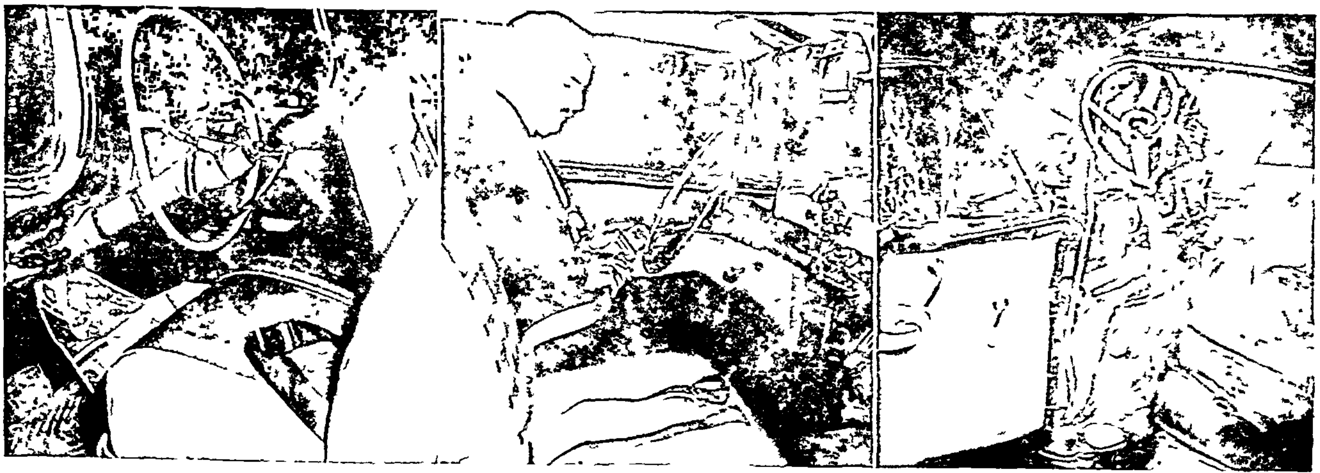
Dr. DuPont Guerry III, chairman of the department of ophthalmology at the Medical College of Virginia, is recommending that a board of ophthalmologists, working through the A.M.A., urge states to determine "vital functions" relating to auto safety. He says that one of the most pressing problems is the wrap-around windshield, with its "terrific visual distortion due to prismatic effect, increased glare because of the focusing of extraneous light . . . and insuperable diplopia from ghost images."

The curved windshield is just one aspect of auto design accused of hampering auto safety. Dr. Horace E. Campbell of Denver points out: "There has been no real change in construction of the motorcar bumper since it was first installed as an accessory some 35 years ago. Many of our present serious crashes would be minor incidents if the bumper had been improved as much as the motor." Only recently have some auto makers begun to adopt safety as a selling point: pop-out windshields, hold-tight door latches, padded instrument panels, collapsible steering wheels, more firmly anchored seats, and shoulder straps.

But no single safety device has been more effective in a crashing auto than the properly installed seat belt. On this the experts agree, especially in a market of high speed, power brakes, and trigger-happy driver feet.

Doctor and Wife Saved

Not long ago Dr. and Mrs. George Spielman of Mandan, N. D., were persuaded by another Mandan physician to install safety belts in their car. As the couple started out on a vacation trip, another auto turned into their path. Dr. Spielman slammed on the brakes, and swerved to avoid a crash. His auto somersaulted into a ditch and landed on its top as the windshield shattered. Inside, he and his wife were suspended safely by their seat belts. In another case, two cars crashed head on. The couple in one car with seat



Air Force Lieut. Billy J. Yeiser installed a seat belt in his car last spring. Within 24 hours his auto was struck head on, *left*, by a car in southern Illinois. He suffered only minor injuries, while two persons were killed and six hurt in the other auto. *Center*, proper use of seat belts. *Right*, the human-impact result of another head-on collision in which there were no seat belts (National Safety Council photos).

belts were released from a hospital the next morning after observation. There were no seat belts in the other auto; one occupant was killed, and the other was in the hospital for two months.

State and county medical societies are just beginning to get into the traffic-safety picture with committees of their own, as the result of last June's A.M.A. resolution, but a few of them have been active in the field for years. In Virginia, for example, several county medical societies made a joint appeal to the governor and the legislature for tests of suspected drunken drivers and for mandatory jail sentences of at least 24 hours against those convicted.

Is It a New Medical Specialty?

The more some physicians look into traffic safety, the more they seem to see the possibility of a new medical specialty (one general practitioner suggested it be called "medicotrafficology"). In the traffic-safety field they find essentials of over a half-dozen other specialties: preventive medicine, psychiatry, epidemiology (the Harvard school suggests that state motor-vehicle bureaus hire full-time epidemiologists), neurosurgery, ophthalmology (the Harvard school claims that carbon monoxide inhaled from smoking three cigarettes has the same anoxic influence on night vision as going to an altitude of 7,500 ft.), toxicology, orthopedics, and industrial health. (The accident rate of the Third Avenue transit system in New York City was cut in half by a company medical program that included psychological tests for vehicle operators. Absenteeism went down, there was a reduction of 3,000 accidents a year, and the company saved $100,000 in compensation and sickness benefits.)

But it is in the economics of the problem that physicians can see tremendous waste in dollars that might be used to save human life. In the past 40 years in the United States we have spent 75 billion dollars for roads and nearly two and a half trillion dollars for new vehicles, accessories, and fuel. Traffic accidents last year cost 4.4 billion dollars, according to the U. S. Public Health Service.

Yet, the Association of Casualty and Insurance Companies estimates that less than 4 million dollars a year is spent for all forms of highway safety and that "a miniscule of that amount went into the search for an answer to the riddle of the human being at the wheel." So, to many, the traffic problem has become a major medical problem by the very nature of its bloody eruption into a socioeconomic crisis. As Dr. Woodward puts it: "When one car in twelve is involved in a serious crash each year, when speed is a factor in one-third of our fatal accidents, when the drinking driver is in one-fourth of our fatal accidents, when the automobile death rate as figured in man years of life lost ranks next to our main killers of cardiovascular disease and cancer, it is time indeed to answer Cain's query and say: 'Yes, I am my brother's keeper.' "

COUNCIL ON PHARMACY AND CHEMISTRY

Report to the Council

The Council has authorized publication of the following report.

H. D. Kautz, M.D., *Secretary.*

It is generally recognized that the final evaluation of the toxicity of a chemical encountered by humans should be in terms of its effect on man. The following report concerns the first experimental study of the storage, excretion, and possible clinical effects in man of chlorophenothane (DDT) given in many small daily doses. By relating excretion to dosage, the study makes practical the quantitative estimation of the dosage for persons with extensive occupational exposure to DDT, and thus eventually makes possible evaluation of the effect of DDT on man after years of exposure. This is important, for DDT continues as the predominant residual insecticide for agricultural and public health use. Any effects of repeated exposure would appear on the average most promptly, most frequently, most diversely, and most severely among persons whose exposure has been long and intensive.

Bernard E. Conley, *Secretary*
Committee on Pesticides.

THE EFFECT OF KNOWN REPEATED ORAL DOSES OF CHLOROPHENOTHANE (DDT) IN MAN

Wayland J. Hayes Jr., M.D.
William F. Durham, Ph. D.
and
Cipriano Cueto Jr., B.S., Savannah, Ga.

Much knowledge is available regarding the effect of repeated doses of chlorophenothane (DDT) on a variety of animals. Significant interspecies variation has been found in its toxicity when given orally, the storage of DDT in fat, and the conversion of DDT to 1,1-dichloro-2,2-bis(*p*-chlorophenyl)ethylene (DDE). Some other aspects of the pharmacology of DDT have not been investigated sufficiently to determine whether interspecies differences are present. A final evaluation of the effect of DDT on man must be made with human subjects. The practical importance of the problem is evident from the fact that a greater tonnage of DDT than of any other insecticide is used in agriculture, that DDT occurs regularly in prepared meals,[1] and that it is stored in the fat of most persons in the general population.[2]

From the Communicable Disease Center, Public Health Service, U. S. Department of Health, Education, and Welfare.

Read before the American Association for the Advancement of Science, Panel Discussion on Hazardous Household Chemicals and Agricultural Poisons, sponsored by the Committee on Toxicology and the Committee on Pesticides, American Medical Association, Atlanta, Ga., Dec. 29, 1955.

An investigation was designed with the following objectives: 1. Study of possible clinical effects of different dosage levels. Only those dosage rates were chosen that were estimated to be harmless, for it was not the purpose of the study to cause illness. The highest dosage rate chosen (0.5 mg. per kilogram of body weight per day) is about 200 times greater than the dosage to which the general population is exposed (0.0026 mg. per kilogram per day) but 5 times less than the smallest dosage that is estimated to cause transient, mild sickness (2.5 mg. per kilogram per day). This latter estimate was made on the basis of animal experiments and on the basis of the smallest single dose of DDT known to produce mild illness in man.[3] This estimate should not be confused with the dosage of 2.5 mg. per day (about 0.035 mg. per kilogram per day), which Fitzhugh estimated could be ingested for long periods without injury.[4] 2. Determination of the relationship between oral dosage of DDT and the storage of DDT-related compounds in adipose tissue at equilibrium. Improvement made in chemical methods during the study permitted a third objective to be added: 3. Determination of the relationship between oral dosage of DDT and the urinary excretion of bis(p-chlorophenyl) acetic acid (DDA).

Permission was obtained from the Bureau of Prisons, U. S. Department of Justice, to carry out the experiment using volunteers in a federal correctional institution. The study was explained to almost the whole population of the institution. Detailed explanations were made to those who were interested in participating. The men who tentatively volunteered were examined and were accepted if they proved to be qualified physically and in other ways. The fact that participation was at all times strictly voluntary must be emphasized; each man was free to leave the study at any time.

Methods

The selected volunteers were divided into six groups, three entering the study in February, 1954, and three in May, 1954. As shown in table 1, groups 1 to 3 received dosages of 0, 3.5, and 35 mg. of DDT per man per day, respectively, for periods ranging up to 18 months. Each dose was carried in a capsule of oil containing the appropriate concentration of recrystallized p,p'-isomer of DDT.

Although groups 4, 5, and 6 received the same dosages as groups 1, 2, and 3, respectively, two major changes were made: technical DDT was used, and it was administered as an emulsion in milk rather than in capsules. The capsules were originally chosen for groups 1 to 3 because of their convenience. They were abandoned for groups 4 to 6 in favor of a formulation more nearly like a "natural" residue and also for administrative reasons. The emulsion concentrates were prepared by homogenizing 5 gm. of gum arabic, 90 cc. of water, 10 cc. of 95% ethyl alcohol, and 15 cc. of peanut oil. For groups 5 and 6, the peanut oil moiety of the formulation contained 0.538 and 5.38% of technical DDT respectively. These concentrations were chosen in order that 5 cc. of the two emulsion concentrates would contain 3.5 and 35 mg. of DDT respectively. Before being offered to the men, 5 cc. of the appropriate emulsion concentrate was diluted with milk to a total volume of about 2 oz. Chemical analyses of capsules and emulsions gave values for the concentration of DDT that were in excellent agreement with intended values. Analyses indicated that the emulsions were stable in DDT content for at least two months, a longer period than that required for the experiment, because new supplies of emulsion were prepared at monthly intervals.

Proper dosage for the different groups of men was assured by packaging each capsule and marking each bottle of emulsion for individual volunteers. The capsules, regardless of their DDT content, were identical in appearance. The same was true of the emulsions. The men were told the dosage rates and the design of the experiment before they volunteered, but no volunteer was told his individual dosage. Furthermore, this detail was not revealed to the medical officer stationed at the institution nor to the medical technical assistants. All of the volunteers, irrespective of group, were given capsules (or emulsion) containing no DDT for 17 days at the beginning of the study; the regular doses were begun without notice.

Samples of the meals served the men in the dining hall were analyzed for DDT content to determine the exposure that might be expected from this source. Complete meals for a total of four days were analyzed. The results are shown in table 2. Considerable variation was found among foods and even among whole meals with respect to DDT content; however, the mean

TABLE 1.—*Outline of Experiment*

		Dosage			No of Men					
Type of DDT	Group No	Added, Mg./Man/Day	Total (Range),* Mg /Kg /Day	Case No	Entering Experiment	Completing 17 Predosage Days	Completing 1 Mo of Dosage	Completing 12 Mo of Dosage	Completing 18 Mo of Dosage	Completing Final Examinations

	6	35	0.36-0.57	42-50	9	8	8	6	3	7
Total					51	47	44	14	5	35

* The total dosage included dietary DDT as well as the administered dose. Dietary DDT, resulting from agricultural residues, was estimated at 0.184 mg./man/day on the basis of the analyses of whole meals. The total dosage varied somewhat according to the weight of the men.

daily DDT intake of 0.202 mg. was in reasonable agreement with the value of 0.184 mg. reported by Walker and co-workers[1] for a larger series of sample meals. The value of 0.184 mg. per man per day was used in computing the total daily DDT dosage for each man as shown in table 1, because this value is based on a large number of samples and is the best estimate of the true average now available. This is especially true because the figures in table 2 would agree better with those given by Walker and his colleagues if it were not for the values obtained for breakfast and especially lunch on Aug. 25. The value for the breakfast was associated with the finding of 69.6 ppm of DDT in stewed dried fruit. Except for bread, which showed a concentration of 100.9 ppm of DDT, the DDT content of the lunch was not unusual. There was no record of the kind of shortening used in this bread; however, it was later learned that bread, all of which was baked at the institution, was occasionally made with lard (which contained, on analysis, a relatively high concentration of DDT) rather than with vegetable shortening (which proved to be of low DDT content). In both the fruit and the bread the DDE concentration was relatively low.

Table 2.—*DDT and DDE Found in Typical Meals Served to Volunteers*

Daily Mean		202.1	50.4

Volunteers were checked for previous exposure to insecticides (which in all instances was negligible) and were given a careful symptoms review, a general physical examination, and a variety of laboratory tests prior to their entrance into the project and at six-month intervals thereafter. Particular emphasis was given to the neurological examination and liver function tests, since in experimental animals the major effects of DDT are on the nervous system and the liver. The liver function tests carried out were sulfobromophthalein retention and plasma cholinesterase level. The electrometric method of Michel[5] was used for the cholinesterase determination. Vorhaus and co-workers[6] have shown that plasma cholinesterase level is a significant index of hepatic function. Preliminary studies with monkeys have indicated that some decrease in plasma cholinesterase level might be associated with high DDT dosage levels.

In all instances, fat samples for the determination of DDT-derived compounds were obtained by biopsy, using local procaine anesthesia. Blocking was done around the operative site, and it was generally possible to avoid infiltration of the tissue that was later excised. The biopsy specimen was usually taken through a 1.5-in. incision from the subcutaneous adipose tissue of the abdomen. Body fat content was calculated from specific gravity, which was determined by weighing the individual under water.[7] Analyses for DDT, DDE, and DDA were made by the Schechter-Haller method. The procedure used for adipose tissue has been described by Mattson,[2] and the procedure used for urine has been described by one of us (C. C.).[8]

During the study some of the men left the institution by transfer or parole or on other authority. Whenever sufficient notice was given, the men were completely reexamined shortly before their participation in the project ended. During the course of the study, 126 complete sets of examinations were carried out on the 51 volunteers. Table 1 indicates the number of men in each group who participated for specified periods. Of the 47 men who remained in the study longer than 17 days, biopsy specimens from 35 were taken, and they were completely reexamined after their last dose of DDT. Two men refused the final biopsy but underwent the other tests. Four others were released on such short notice that no final examination was possible, but a biopsy was performed by a private physician after their release. Thus, of the 47 volunteers, only 6 were discharged in such a way that they received no final biopsy or examination.

Results

Condition of Volunteers at Start of Experiment.—The condition of the volunteers on entering the experiment is shown in part in table 3. The men who entered in February varied in age from just under 21 to just over 50 years; those who entered in May varied from just over 21 to a little over 40. All the men except three were essentially normal, not only regarding values shown in table 3 but in other respects as well. Two of the abnormal men (cases 7 and 29) were in control groups and, therefore, not subject to any influence of DDT. They were asymptomatic and afebrile throughout. The patient in case 7 had a white blood cell count that varied from 13,400 to 20,200 per cubic millimeter over a period of several months. He showed as high as 12% of eosinophils, but the differential count was otherwise normal. There was moderate lymphadenopathy. Despite a thorough examination, the underlying cause of the difficulty was not determined. It was established that leukemia was not present. The patient in case 29 had albuminuria and microscopic and other findings consistent with a diagnosis of latent chronic nephritis. Illness did not progress in either subject during the study; in fact, the condition of the patient in case 7 returned toward normal.

The third subject (case 9) had abnormally high sulfobromophthalein retention on initial examination; his plasma cholinesterase value was within normal limits. He received 3.5 mg. of DDT per day and was asymptomatic during the 89 days he remained in the experiment. Because of inadequate notice of his departure from the institution, no final studies were done on this man.

Two volunteers who gave a history consistent with infectious hepatitis were taken into the experiment despite the effect of very large doses of DDT on the liver of experimental animals and, according to one author,[9] of man One man (case 5), a control patient, received no DDT, the other (case 20) received 35 mg. of DDT per day. Jaundice did not recur in these men, and they showed no abnormality in liver function tests during the experiment

Effect on Health—Four men quit the experiment of their own accord One subject (case 0) quit only one day after the first biopsy, thus, except for the biopsy, he was not a part of the experiment. A second man (case 8) from the same control group considered that his health had been injured after a total of 182 days in the study (no DDT given). He refused a final biopsy. Physical and laboratory examination disclosed no abnormality except a dermatitis of the right leg, which he attributed to his participation A volunteer (case 16) who received 3 5 mg of DDT per day also refused a final biopsy and quit just before he was transferred from the institution He had participated for 155 days and had received 138 doses of DDT He had several complaints, including pain every day in every bone, occasional headache, and tearing of the right eye He submitted to complete physical and laboratory examination, and all findings were normal His complaints obviously were of psychoneurotic origin, and even the man himself did not seem to take them seriously One volunteer (case 19) receiving 35 mg of DDT per day quit after 21 days (DDT given last 4 days) He had no specific complaints but was unwilling to continue

Of the total of 37 volunteers who were questioned specifically on the matter just after completion of their participation in the study, only the two mentioned considered that their health had been adversely affected. In one instance of weight loss, the possibility of injury caused by DDT exposure was considered. The subject (case 11) had a history of a 7 kg (15 lb) fluctuation of weight before entering the experiment. His weight loss of 6 kg. (13 lb.) during the study was associated directly with hard physical work in a hot environment. He accepted this explanation and, with the onset of cool weather, regained his weight while continuing to take DDT.

Changes in certain important items that can be measured were tabulated and compared for the six groups for the periods 5 to 6, 7 to 8, 9 to 10, 11 to 12, and 12 or more months of dosage respectively. It was necessary to tabulate changes rather than observed values because, as some men completed their participation, the composition of the sample shifted. For example, the average weight of men in group 1 was less after five to six months than at the beginning of the experiment because a heavy man had dropped out, most of the men who remained had gained weight, and the average change of weight was a slight gain The items examined in this way were weight, hemoglobin level, red blood cell count, white blood cell count, percentage of polymorphonuclear leukocytes, heart rate (at rest, just after exercise, and after two minutes of rest), systolic blood pressure and pulse pressure (at rest and after exercise followed by two minutes of rest), and plasma cholinesterase level. Although changes were observed in all of these values, none were correlated consistently with increased dosage of DDT or with increased duration of exposure Since the changes were random in distribution and not unusual in degree, they must be attributed to normal variation. No significant change in sulfobromophthalein retention was noted. This item was not tabulated because the retention values for most of the men were zero before and after exposure to DDT In a similar way, chest x-ray findings were not tabulated, for they all were essentially normal

*Recorded as increase or decrease of strokes per minute compared to the rate for the same person just before exercise followed by 2 min of rest

The initial review of symptoms revealed a great variety of minor complaints. These complaints were not unusual, and the men undoubtedly were predisposed to some of them by their confinement. A small number of minor physical defects was revealed by examination. In subsequent examinations no increase or significant change in abnormal physical findings was discovered. There was some tendency for the volunteers to give fewer compaints at subsequent interviews.

Results of following tests were taken into consideration in the neurological examination: gait, including ability to walk on toes and heels; coordination including Romberg, finger to nose, heel to shin, adiadochokinesia, rebound, past-pointing, tremor, handwriting, and "tongue twisters"; deep reflexes, superficial reflexes, and clonus; muscle strength, including all major movements of the neck, shoulder, elbow, wrist, fingers, hip, knee, and ankle; sensation, including light touch, pinprick, two-point discrimination, position sense, vibration sense, stereognosis, and differentiation of heat and cold; and function of the cranial nerves, including identification of an odor, visual fields, reactivity of pupils, extraocular movements, strength of bite, sensation of the face, coordination and strength of facial muscles, hearing, pharyngeal reflex and voice, and protrusion of the tongue. All of the participants remained normal in regard to these neurological tests; of particular interest, they showed no loss of coordination and no indication of tremor.

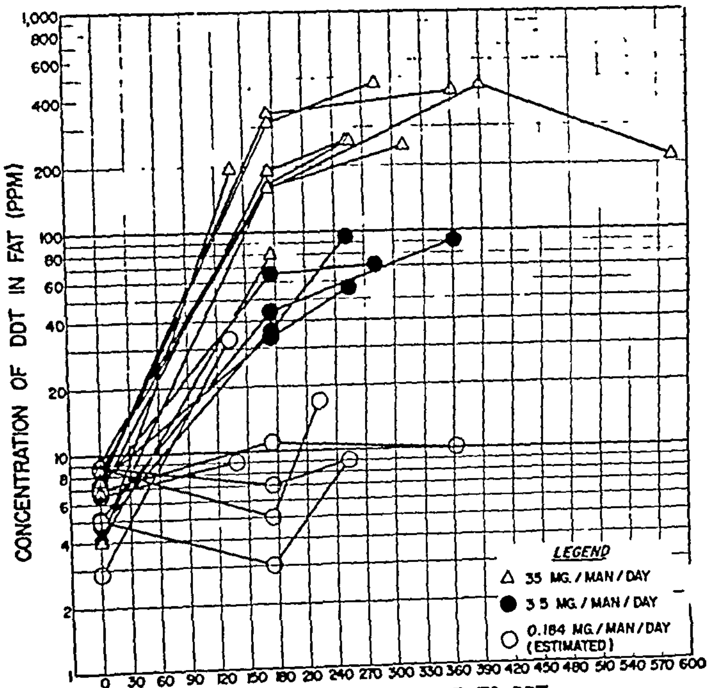

Fig. 1.—Storage of DDT in the subcutaneous fat of volunteers given indicated doses of recrystallized *p,p'*-isomer of DDT.

In contrast to the random and normal variation encountered in other tests, the values for the storage and excretion of DDT-derived materials showed a strong correlation with dosage and with duration of exposure. In conclusion, during the entire study, no volunteer complained of any symptom or showed any sign of illness that did not have an easily recognized cause clearly unrelated to exposure to DDT.

Storage of DDT-Derived Materials.—The storage of DDT in subacutaneous fat by groups 1, 2, and 3 is shown in figure 1 and that by groups 4, 5, and 6 in figure 2. It is clear that storage was directly proportional to dosage. The graphs suggest that, at the dosages used, human males achieve storage equilibrium for DDT in about a year, but further observation is necessary to establish this conclusion firmly. The absolute variation was greater among the higher storage level values, but, as shown by a comparison of the coefficients of variation in table 4, the relative variation remained about the same.

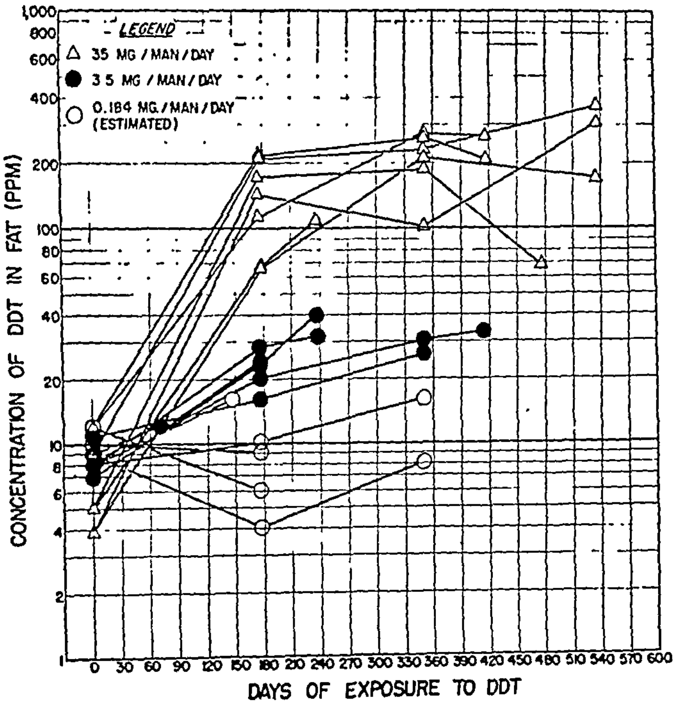

Fig. 2.—Storage of DDT in the subcutaneous fat of volunteers given indicated doses of technical DDT.

An unexpected finding was the difference in the amount of storage at the same dosage in connection with recrystallized DDT and technical DDT respectively. Rats show a difference in this regard, but it is smaller in degree and opposite in direction; that is, under conditions of equal exposure, rats store more technical DDT than recrystallized DDT. At a dosage of about 0.5 mg. per kilogram of body weight per day for 10 months or more, the volunteers stored recrystallized DDT in their fat at a concentration of 216 to 466 ppm (mean, 340 ppm). At the same dosage for the same period, other volunteers stored technical DDT at a concentration of 101 to 367 ppm (mean, 234 ppm). Unfortunately, it is impossible to determine whether the difference was associated with the character of the DDT samples or with the formulations in which they were administered. As shown in table 5, however, the level of statistical significance for the difference between the storage of recrystallized and of technical DDT is very nearly as great as the signi-

ficance of differences based on dosage and on duration of exposure calculated in the same way. These latter differences, of course, have a simple, biological explanation. The statistical analysis indicates that the difference between the storage of recrystallized and of technical DDT cannot be ignored but should be the subject of further studies in the hope that a reasonable biological and/or chemical explanation may be found.

Storage of DDE in subacutaneous fat is shown in table 3 and figure 3. In the presence of ordinary dietary exposure to DDT, the storage of DDE showed about the same variability as the storage of DDT. For the men entering the experiment the average storage of DDE was 11.2 ±0.74 ppm, giving a coefficient of variation for the standard error of 6.0%; the average storage of DDT was 7.4 ±0.37, giving a coefficient of variation of 5.0%. Men who ate recrystallized DDT showed a definite increase in the absolute amount of DDE stored. After six months at a dosage of 35 mg. per man per day, eight men showed an average DDE storage of 32.6 ±7.0 ppm as compared to 12.3 ±1.5 ppm for the same individuals upon entering the experiment. There was a further increase of DDE storage during additional months of exposure; however, DDT was stored in so much greater concentrations that the relative storage of DDE decreased sharply. Thus, after six months at a dosage of 35 mg. per man per day, eight men stored only 14% of their total DDT-derived material in the form of DDE, as compared to 65% for the same persons at the beginning of the experiment.

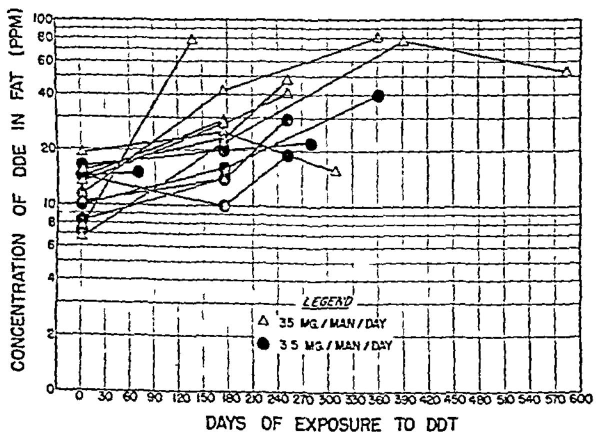

Fig. 3.—Storage of DDE in the subcutaneous fat of volunteers given indicated doses of recrystallized *p,p'*-isomer of DDT. For graphic clarity, values for the control group have not been plotted.

The storage of DDE by men who ate technical DDT presented a different picture. Until 18 months of exposure, there was no clear evidence that those men stored any more DDE after exposure than they did before; however, at 18 months, the only three samples available showed DDE concentrations of 85, 42, and 28 ppm. Although these values constituted only 16% of the total storage of DDT-derived material, they are all well above average for general population figures and thus indicate the conversion of technical DDT to DDE in the volunteers. The question is complicated by the fact that the chemical method does not permit measurement of DDE when it constitutes less than 10% of the total DDT-derived material in the eluate from the chromatographic column. It is possible that a limitation of the chemical methodology may account for the apparent difference in the way in which human beings handle recrystallized DDT and technical DDT.

No conclusion can be reached regarding the time at which equilibrium is reached in the storage of DDE. Figure 3 might be thought to suggest the establishment of equilibrium at about a year, but the number of values available for comparison is very small. In animals, it generally requires longer to establish storage equilibrium for DDE than for DDT.

Table 6.—*Variability in Fat Storage of DDT Expressed on the Basis of Concentration and Total Amount Stored*

Duration of Exposure, Mo.	Daily DDT Dosage, Mg.	No. of Men	DDT Storage in Fat: Concentration: Mean, Ppm	Concentration: Vx̄,* %	Total Amount: Mean, Gm.	Total Amount: Vx̄,* %

	35	8	270.0	15.9	3.280	15 2

* Coefficient of variation of the standard error of the mean.

As an alternative to the use of concentration as a measure of DDT storage, the total amount of DDT stored per man was considered. This value was determined by multiplying the weight of the subject's body fat by the concentration of DDT in his fat. In table 6, the results of this study are shown. It is apparent from inspection of the coefficients of variation that the intergroup differences were about the same, using either DDT concentration in fat or total DDT content as a measure of the magnitude of DDT storage. The average total DDT storage for the highest dosage group after 12 months of exposure was 3.28 gm., based on measured concentration of DDT in fat and estimated total body fat. This average total storage would represent a potential DDT dosage to the average man (70 kg.) of 47 mg. per kilogram. It is unrealistic to suppose that fat would ever be metabolized rapidly enough to cause acute clinical DDT poisoning when the total available dosage is 50 mg. per kilogram or less.

In single specimens of blood taken from 4 men who had received 599 or more doses at the highest rate, DDT was found at a concentration of 1.6 to 4.2 ppm or an average of 2.8 ppm. DDE was found in these specimens at concentrations of 1.3 to 3.1 ppm or an average of 1.9 ppm. In the individual samples, DDE constituted 34 to 45% of the total DDT-derived material. Specimens of saliva collected the same day from the same 4 men contained no detectable DDT-derived material. Results were also negative for a single specimen of bile diluted with intestinal juice.

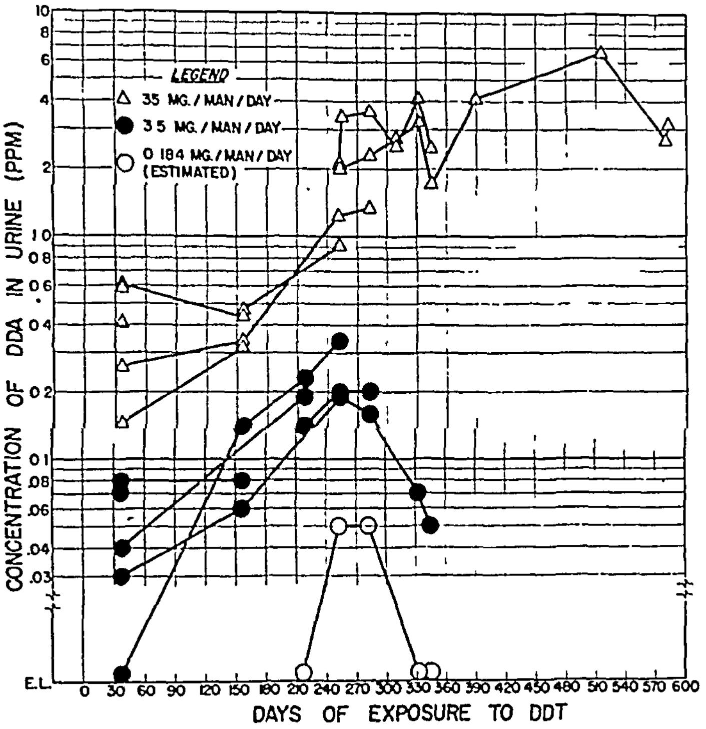

Fig. 4.—Urinary excretion of DDA by men given indicated dosage of recrystallized *p,p'*-isomer of DDT. E. L. = experimental limit, a concentration too small to be detected by the available chemical method.

Excretion of DDT-Derived Materials.—Urinary excretion of DDA is shown in figures 4 and 5. The study of urinary excretion was exploratory at first. The method for isolating DDA from urine was perfected during the course of the experiment.[8] For this reason, the early values are considered less accurate than the later ones; even so, certain conclusions are justified. The daily ingestion of 3.5 mg. or more of DDT led to the excretion of substantial amounts of DDA in about 30 days. There were no values to indicate how early excretion might be detected regularly; however, even subjects with only dietary exposure to DDT occasionally excreted DDA at concentrations that approached 0.2 ppm, indicating a distinct relation between DDT dosage and the amount of DDA excretion. The excretion of DDA also increased with the duration of DDT exposure. The highest concentration of DDA observed in a single sample was 9.6 ppm. Of particular interest was the study of 24-hour urine samples recorded in table 7. These samples show the marked variation of DDA concentration characteristic of samples collected at a single voiding. When the concentration was multiplied by volume to give total DDA content in milligrams, the variation was reduced. Thus, considering all observed values, the coefficient of variation for DDA concentration was 16.3%, whereas that for total DDA content of the same samples was only 5.4%. The variation between samples of urine from a given man taken on different days tended to be about the same as the variation between samples from different men taken on the same day. The specific gravity of urine samples tends to be inversely proportional to the volume; however, the variation in DDA concentration values for urine samples collected at a single voiding could not be decreased significantly by adjusting the values in accordance with the specific gravity of the various samples. In view of the results with 24-hour samples, this may indicate that the excretion of DDA does not parallel that of sodium chloride and other solids, which play a major role in the determination of specific gravity.

Expressed as DDT, the DDA found in the 24-hour urine samples varied from 4.8 to 9.6 mg. and averaged 6.7 mg. per sample. Thus, after storage equilibrium had been achieved, it was possible, through urinary excretion, to account for 13.6 to 27.4% or an average of 19.0% of the entire ingested dose. Figures 4 and especially 5 suggest that equilibrium of DDA excretion is reached in about a year. A specimen of feces from a man at the highest dosage level contained DDT (2.6 ppm) and DDE (2.7 ppm). Difficulty with isolating DDT-deriven material from human feces is great, especially with the acid fraction (DDA and related materials). DDA was not demonstrated, but its presence, or the presence of related material, is not excluded.

Comment

As shown in table 8, the median storage of DDT found in the volunteers before they entered the experiment corresponded well with that reported by Laug and co-workers [10] for a series of samples collected from the general population sometime before 1951. Laug and his colleagues did not distinguish DDE. The estimation of DDT reported in that paper is more comparable with the estimation of DDT in the present paper than with the estimation of DDT plus DDE. The distribution of the present values for DDT storage differs from the distribution reported by Laug in that the more recent work shows a concentration of figures near the mean and no values at all corresponding to Laug's high and low ranges. This difference in distribution may be explained by a more constant and more

controlled use of DDT in agriculture at the present time. Earlier use of the pesticide was more sporadic and may have been less well regulated. The difference in distribution may also be related to differences in chemical method. Early unpublished studies carried out in this laboratory at about the same time as those of Laug show the same distribution and general magnitude of values as those reported by Laug. These early studies involved sufficient differences in chemical method from those now used that it is difficult to evaluate the results. Interpretation of early zero values appears especially difficult.

The concentration of DDT stored in the fat of the volunteers at apparent equilibrium after the highest dosage was almost as high as that for one man with extensive occupational exposure who showed 648 ppm of DDT and 434 ppm of DDE. The DDE stored by the volunteers constituted only an average of 16% or less of their total DDT-derived material, whereas the corresponding value for the man with occupational exposure was 40%. The difference was probably related to the duration of high exposure—18 months or less for the group and five years for the worker.

Summary and Conclusions

With full knowledge of the plan of the study and with complete freedom to withdraw at any time, 51 men volunteered to take daily, oral doses of DDT for different intervals. One-third of the men received no DDT except that in the ordinary diet; one-third received 3.5 mg. per man per day; and one-third received 35 mg. per man per day, which is about 200 times the daily rate at which an average man receives DDT from his diet. During the entire study, no volunteer complained of any symptom or showed, by the tests used, any sign of illness that did not have an easily recognized cause clearly unrelated to exposure to DDT.

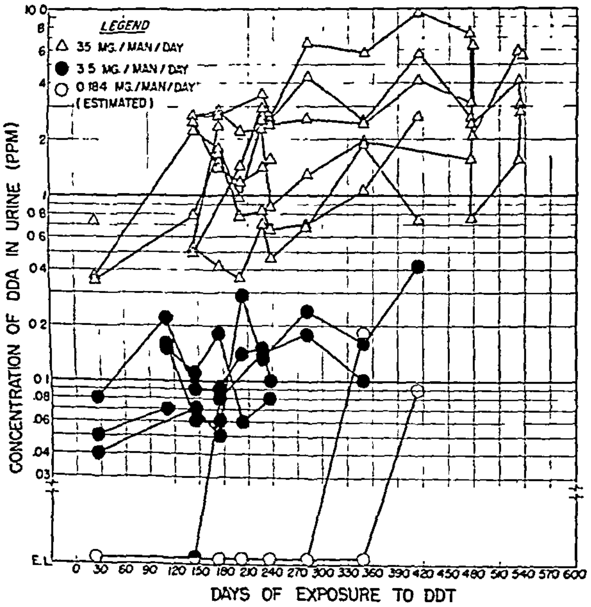

Fig. 5.—Urinary excretion of DDA by men given indicated dosage of technical DDT. E. L. = experimental limit, a concentration too small to be detected by the available chemical method.

The storage of DDT in man is proportional to dosage. There was an unexplained difference in the storage of recrystallized and of technical DDT. The pure material was stored in fat at an average concentration of 340 ppm and the technical material at an average concentration of 234 ppm after an identical dosage of 35 mg. per man per day. It appears that, at the dosages used, human males achieve maximum storage of DDT in about a year and thereafter store no more of the material despite continued intake. Men who ate DDT showed an absolute increase in the storage of DDE. No conclusion could be reached regarding the time at which equilibrium is reached in the storage of DDE. The storage of DDT and the storage of DDE show about the same relative variation (coefficient of variation) at different dosage levels, but the absolute variation is, of course, greater at higher dosages.

Table 8.—*Range of Concentration of DDT Found in Human Fat*

Range	Cases, %	
Ppm DDT	Laug Report	This Study
0.0	20	0
0.1-1.0	9	0
1.1-5.0	28	25
5.1-10.0	28	61
10.1-20.0	12	14
Over 20.0	3	0

A method for determining the concentration of DDA in urine was perfected during the course of the study. The excretion of DDA is proportional to the dosage of DDT. This makes possible an objective measurement of DDT absorption by the determination of DDA in urine and greatly expands the possibility of practical study of formulators and others who have occupational exposure to DDT. It was possible to account for about 20% of the DDT administered, in terms of DDA excreted in the urine. The results indicate that a large safety factor is associated with DDT as it now occurs in the general diet.

The chlorophenothane (DDT) capsules were supplied by R. P. Scherer Corporation, Detroit.

9. Naevestad, R.: Poisoning with DDT Powder and a Couple of Other Cases of Poisoning, Tidsskr. norske laegefor. 67: 261-263, 1947; abstracted, Bull. Hyg. 22: 580 (Sept.) 1947.
10. Laug, E. P.; Kunze, F. M., and Prickett, C. S.: Occurrence of DDT in Human Fat and Milk, A. M. A. Arch. Indust. Hyg. 3: 245-246 (March) 1951.

In single specimens of blood taken from 4 men who had received 599 or more doses at the highest rate, DDT was found at a concentration of 1.6 to 4.2 ppm or an average of 2.8 ppm. DDE was found in these specimens at concentrations of 1.3 to 3.1 ppm or an average of 1.9 ppm. In the individual samples, DDE constituted 34 to 45% of the total DDT-derived material. Specimens of saliva collected the same day from the same 4 men contained no detectable DDT-derived material. Results were also negative for a single specimen of bile diluted with intestinal juice.

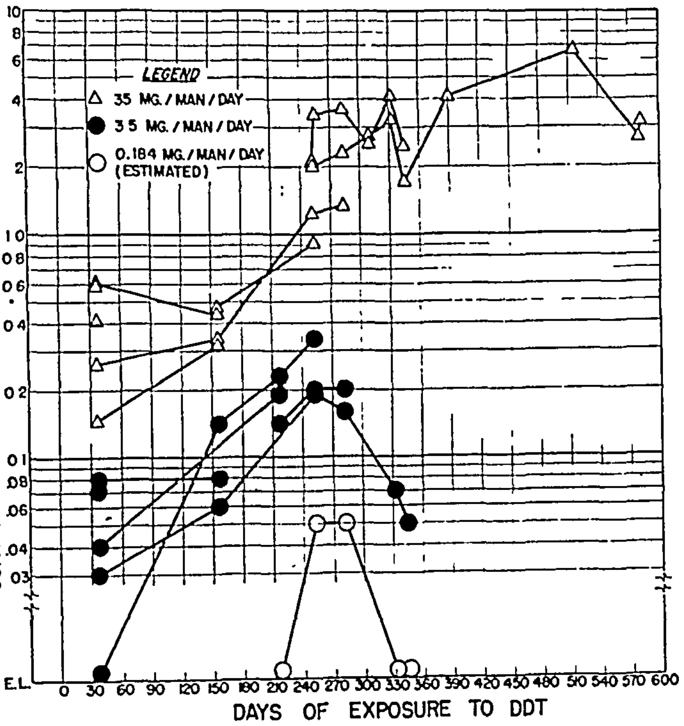

Fig. 4.—Urinary excretion of DDA by men given indicated dosage of recrystallized *p,p'*-isomer of DDT. E. L. = experimental limit, a concentration too small to be detected by the available chemical method.

Excretion of DDT-Derived Materials.—Urinary excretion of DDA is shown in figures 4 and 5. The study of urinary excretion was exploratory at first. The method for isolating DDA from urine was perfected during the course of the experiment.[8] For this reason, the early values are considered less accurate than the later ones; even so, certain conclusions are justified. The daily ingestion of 3.5 mg. or more of DDT led to the excretion of substantial amounts of DDA in about 30 days. There were no values to indicate how early excretion might be detected regularly; however, even subjects with only dietary exposure to DDT occasionally excreted DDA at concentrations that approached 0.2 ppm, indicating a distinct relation between DDT dosage and the amount of DDA excretion. The excretion of DDA also increased with the duration of DDT exposure. The highest concentration of DDA observed in a single sample was 9.6 ppm. Of particular interest was the study of 24-hour urine samples recorded in table 7. These samples show the marked variation of DDA concentration characteristic of samples collected at a single voiding. When the concentration was multiplied by volume to give total DDA content in milligrams, the variation was reduced. Thus, considering all observed values, the coefficient of variation for DDA concentration was 16.3%, whereas that for total DDA content of the same samples was only 5.4%. The variation between samples of urine from a given man taken on different days tended to be about the same as the variation between samples from different men taken on the same day. The specific gravity of urine samples tends to be inversely proportional to the volume; however, the variation in DDA concentration values for urine samples collected at a single voiding could not be decreased significantly by adjusting the values in accordance with the specific gravity of the various samples. In view of the results with 24-hour samples, this may indicate that the excretion of DDA does not parallel that of sodium chloride and other solids, which play a major role in the determination of specific gravity.

Expressed as DDT, the DDA found in the 24-hour urine samples varied from 4.8 to 9.6 mg. and averaged 6.7 mg. per sample. Thus, after storage equilibrium had been achieved, it was possible, through urinary excretion, to account for 13.6 to 27.4% or an average of 19.0% of the entire ingested dose. Figures 4 and especially 5 suggest that equilibrium of DDA excretion is reached in about a year. A specimen of feces from a man at the highest dosage level contained DDT (2.6 ppm) and DDE (2.7 ppm). Difficulty with isolating DDT-deriven material from human feces is great, especially with the acid fraction (DDA and related materials). DDA was not demonstrated, but its presence, or the presence of related material, is not excluded.

Comment

As shown in table 8, the median storage of DDT found in the volunteers before they entered the experiment corresponded well with that reported by Laug and co-workers[10] for a series of samples collected from the general population sometime before 1951. Laug and his colleagues did not distinguish DDE. The estimation of DDT reported in that paper is more comparable with the estimation of DDT in the present paper than with the estimation of DDT plus DDE. The distribution of the present values for DDT storage differs from the distribution reported by Laug in that the more recent work shows a concentration of figures near the mean and no values at all corresponding to Laug's high and low ranges. This difference in distribution may be explained by a more constant and more

TABLE 7.—*Recovery of DDA from Twenty-Four-Hour Urine Specimens from Volunteers Who Had Received DDT at the Rate of Thirty-Five Milligrams per Man per Day for Sixteen or More Months*

* Coefficient of variation of the standard error of the mean.

† (Mg./kg. of DDA) × (kg. of urine) × 1.26. This latter factor (the dividend obtained by dividing the molecular weight of DDT by the molecular weight of DDA) serves to convert DDA values to DDT equivalent values.

THE PRESIDENT'S PAGE

A MONTHLY MESSAGE

None of us had to register to vote, and perhaps there are some who did not. None of us has to vote on Nov. 6, either, and there are some who will not. None of us even has to vote for all the offices on the ballot, and election results always show that voters skip over many offices. No, there is no one forcing us to register, no one herding us to the polls, and no one compelling us to fill out the complete ballot. Our voting process is entirely voluntary, with the choice of registering and voting up to the individual. We might even say that the right-to-stay-at-home on election day is a privilege we all have. But all privileges are not always advantageous to us and to society, and certainly a decision to ignore voting can be political suicide from the standpoint of the individual, the community, and the nation.

Our whole system of representative government rests on the basic principle that election decisions should be made by all the people eligible to vote. If we fail to vote, we undermine that system of government by destroying its basic principle. If there is a more valuable right of an American citizen than the right to vote, I do not know what it could be. It is a right that must be exercised completely and thoughtfully, beginning with registration and following through to voting for the last candidate on the ballot.

Those of us who have registered have taken the first big step, and we cannot afford to stay home and thus lose our vote like so many have already done by failing to register. The government we have is ours, and the government we are going to get on Nov. 6 is to be ours. That is the way we want it, and that is the way it will stay as long as we conscientiously exercise our right of franchise. The idea that "poor government and bad officials are elected by good citizens who do not vote" is old, but it bears repeating and remembering.

Now is the time to make our decisions on the candidates. Study them and the issues so you will be prepared to vote for those you think will serve your community, state, and nation best. Last-minute decisions in the polling booth are not fair to the candidates, and they are hit-or-miss conclusions. Those we elect on Nov. 6 will be managing our affairs at all levels and introducing legislation for the next few years. After election day it will be too late to complain that we did not know a certain defeated candidate believed as we do. There are only a few days left to learn the candidates and the issues, but, if we are to vote intelligently, it is our duty to know and to decide before going to the polls.

Registration this year is heartening, and there is reason to believe the 61,500,000 votes of 1952, or the 62.7% of the eligible voters, will be surpassed in the coming election. The time we spend learning about the candidates and issues—local, state, and national—is as important as the actual casting of a ballot. There is still time to review records, policies, and pledges and to appraise the candidates. Do not put it off; the time is too short. And do not stop with an analysis of just the presidential, senatorial, and congressional races. Decide on candidates for every state and local office lest you be tempted to vote for someone only because he has a familiar name or he belongs to your party. Every elective office is an important position, and it deserves the attention of all responsible voters.

After you have made your choices, do not fail to vote. Many contests have been decided by a single vote. Our history—past and present—is full of such examples. My own state of California was admitted to the Union by one vote, and I have seen many districts in the nation carried by a single vote. I cast my vote knowing that it can elect my candidate or defeat an opponent. I cast it realizing that my candidate deserves it and needs it if he is to win. One vote can be a powerful force. It wins or loses battles, and we do not have to turn the calendar back too many months to prove dramatically that it does happen.

You undoubtedly have strong opinions about the issues and the candidates, but what good will these be if you fail to exercise your franchise? Your voice will be heard clearly if you speak at the polls in behalf of the issues and personalities you favor.

Doctor, make yourself an appointment to vote on Nov. 6, and do not fail to keep it. You and your government could be a heavy loser if you stay home.

Dwight H. Murray, M.D.,
Napa, Calif.

ORGANIZATION SECTION

LET'S KEEP THE DOOR OPEN

George F. Lull, M.D., Chicago

When the American Legion and the American Medical Association agree—as they already do on many principles and in many areas of activity—they should cooperate to the fullest possible extent, not just for their mutual benefit but for the benefit of all Americans. On the other hand, if and when they disagree on certain points, they must do so calmly, reasonably, and with respect for one another's motives. After all, differences of opinion, and the right to express those opinions, are important ingredients in the democracy to which both groups are dedicated.

That is the essence of my main message. Why does the A. M. A. consider it good policy to repeat and reemphasize that message whenever possible? What has happened in relations between the Legion and the A. M. A. to make such a message necessary? For the benefit of those who may not be familiar with this subject, I shall sketch very briefly the background of the past three years. Also, I would like to report some of the most recent developments bearing on the situation.

Recent Developments

For about 20 years, until June, 1953, the Legion and the A. M. A. had a friendly relationship, in which they exchanged views, cooperated on certain projects, and shared many common objectives. That relationship was based on the fact that both organizations are influential, patriotic groups dedicated to the American way of life and opposed to any trends or influences that would undermine the foundations of our national vitality. Fortunately, that basis for cooperation still exists.

However, the calm water became somewhat choppy after the 1953 Annual Meeting of the A. M. A. At that time the House of Delegates adopted the Association's present policy concerning the federal government's responsibility for the hospital and medical care of veterans with non-service-connected disabilities. That policy—and I want to emphasize this—that policy in no way suggested any change or limitation in the Veterans Administration's program of care for veterans with service-connected disabilities. The A. M. A. heartily supports that program, which is a definite national obligation to veterans who are ill or disabled as a result of their military service. The present A. M. A. policy also does not involve wartime veterans with non-service-connected tuberculosis or neuropsychiatric disorders, whenever local facilities are unavailable. The policy simply recommends that the remaining non-service-connected disabilities—the so-called general medical and surgical conditions that have no relation to military service—should become the responsibility of the individual veteran and his community, instead of the federal government.

For more than a year after the A. M. A. adopted that policy, relations with the Legion were, to put it mildly, not exactly convivial. Most physicians were amazed at some of the extreme and bitter charges made against the medical profession by a few Legion officials. We can only conclude that some of the national and state Legion leaders who were in office at the time either misunderstood or misinterpreted the A. M. A. policy. At any rate, there was a welcome change of atmosphere after the 1954 national convention of the American Legion. The new national commander, Seaborn P. Collins, addressed the A. M. A. House of Delegates later that year at the Clinical Meeting in Miami, Fla. He urged that the controversy over veterans' medical care be removed from the area of name-calling and propaganda, and he emphasized the point that "we are citizens first, and doctors and veterans second."

Suggesting establishment of a liaison arrangement to help work out a better mutual understanding, Mr. Collins told the A. M. A. House of Delegates, "If our two groups approach the subject of medical care for veterans in this sincere, honest and reasonable fashion, I believe that we can resolve our differences, or at least achieve an understanding of each other's position which will permit us to continue to collaborate and cooperate in those fields where we do agree."

As a result of that suggestion, both the Legion and the A. M. A. appointed liaison committees to explore possible areas of agreement. Those committees met several times during 1955 and the early part of this year. They reached agreement on a number of points, but they were far apart on others. However, the important thing is that they got together in an atmosphere of reason, mutual respect, and friendly give-and-take across the conference table. And Dr. Elmer Hess, immediate past-president of the A. M. A., in his term-end report to the House of Delegates in Chicago in June, paid particular tribute to the cooperative spirit of Mr. Collins and Governor George Craig of Indiana, another past-commander of the Legion.

The A. M. A. liaison committee, after presenting its report to the Board of Trustees, was discharged from further duty. The issues in question have been referred back to the Committee on Federal Medical Services of the Council on Medical Service, which will continue its studies in the field of veterans' medical care. At the Chicago meeting, the A. M. A. House of Delegates adopted a report by the Committee on Federal Medical Services that included the following statements:

> The Committee is of the opinion that the American Medical Association and the American Legion should continue to cooperate in an effort to provide the finest medical care for all segments of the American public, with special emphasis on the

---

Secretary-General Manager of the American Medical Association.

Read before the Arkansas Department of the American Legion, El Dorado, Ark., July 20, 1956.

obligations of a grateful nation toward those who have suffered disability as a result of military service. It is the further recommendation of the Committee that both organizations should join in aggressively seeking an adequate program of prevention and treatment of mental disorders.

Another point on which the two organizations have had differences of opinion in the past is the practice of establishing a "presumption" of service connection for veterans' disabilities by legislative action rather than by scientific medical examination. Under this practice, which already includes about 30 specific disabilities, a condition is automatically assumed to be service-connected if it occurs within a certain length of time after discharge from service. This, in effect, is simply an indirect method of increasing the VA load of patients with non-service-connected disabilities. The A. M. A. believes, and has so testified many times before congressional committees, that each case should be determined on an individual basis, after sound, careful, medical examination. It holds that it is medically illogical and economically unsound to pass laws that decree that a disability is automatically classified as service-connected simply because it occurs within one, or two, or three years after military discharge. The result of this trend could well be that Congress would declare all veterans' ailments to be service-connected. It has been encouraging to note that in this session of the 84th Congress the Legion has actively supported only one of the most recent bills proposing still more presumptions of service connection. That bill is H. R. 1618, which involves multiple sclerosis and the chronic functional psychoses.

That, as far as my knowledge goes, is the present situation. The really important point, in my opinion, is the fact that for almost two years now the Legion and the A. M. A. have kept the discussions of these issues on a high level. During that period of time, the problem has been removed from the area of name-calling and propaganda, charges and countercharges, smear tactics and emotionalism. I am sure that I express the hope of the vast majority of both physicians and legionnaires when I say, "Let's keep it that way."

Areas of Agreement and Cooperation

The groups have too much in common—as patriotic Americans, as fellow veterans, as staunch defenders of freedom and democracy, and as partners in several specific projects of mutual interest—to allow differences of opinion over one issue to threaten their fundamental unity of purpose. Whether they ever agree on all aspects of the veterans' medical care problem, they should continue to work together in those areas where their joint efforts will constitute a service to our country. After all, every year in this country thousands of couples celebrate their golden wedding anniversaries. In the vast majority of cases, we would be rather "pollyanna" and unrealistic if we assumed that those couples never had an argument. Nevertheless, whether they argued over in-laws, money, or the husband's cigar smoking, they did not allow such side issues to disrupt their basic unity. They might have not been completely enchanted with one another every hour of every day, but they did not let temporary irritations destroy something far more important. The Legion and the A. M. A., of course, could hardly be described as an elderly married couple, but I think the basic analogy holds true. By keeping differences in proper perspective, they can preserve a working relationship and a common devotion to American ideals that will be of benefit to our nation.

For example, in the broad field of ideology the Legion and the A. M. A. stand together as enemies of communism, socialism, fascism, or any other political, social, and economic philosophy that is contrary to American tradition. The Legion was one of the medical profession's earliest and most helpful allies in its campaign against national compulsory health insurance just a few years ago. The A. M. A. for the past five or six years has contributed annually to help support the All-American Conference to Combat Communism, a project in which the Legion also has been interested. Both organizations are increasing their efforts to develop a positive understanding of Americanism and to urge a wider, more vigorous participation in the duties of citizenship. Both the Legion and the A. M. A. have affirmed and reaffirmed their support of the general principles contained in the so-called Bricker amendment. The purpose of that proposed amendment to the Constitution is to protect the nation and the individual states from unwanted legislation that might be imposed through treaties or executive agreements with foreign countries.

For many years, to mention a specific project of a different kind, the Legion and the A. M. A. have been working together in the field of maternal and child health. In fact, Dr. Garland Murphy of El Dorado, Ark., vice-chairman of the Legion's child welfare commission, is the Legion's representative on the Committee on Maternal and Child Care of the A. M. A. Council on Medical Service. Both the Legion and the A. M. A. actively supported the Mental Health Study Act of 1955, which was passed by Congress last year without a dissenting vote. Under that law, an intensive three-year study is now under way by the Joint Commission on Mental Illness and Health, an organization sponsored by the A. M. A., along with about 20 other groups interested in that field. This is another area where the Legion and the A. M. A. can do much to help solve a major national health problem, for the benefit of veterans and nonveterans alike. There are many other projects, subjects, and ideas on which the American Legion and the American Medical Association already cooperate, already agree, or can do so in the future. Let's keep the door open—by keeping our heads.

MEDICAL CIVIL DEFENSE CONFERENCE

The County Medical Societies Civil Defense Organization will hold its seventh conference on Nov. 10-11, 1956, in Chicago at the Morrison Hotel. The Council on National Defense of the American Medical Association sponsors this yearly conference, which is designed to help local medical and health personnel plan for their roles in civil defense. The conference program, this year, is specifically planned to acquaint individuals at the local medical and health group level with practical information concerning responsibilities, preparation, and coordination of medical and health civil defense activities. Individuals desiring additional information on this conference are requested to contact Mr. Frank W. Barton, Secretary, Council on National Defense, American Medical Association, 535 N. Dearborn St., Chicago 10.

PROGRAM
SATURDAY MORNING—NOV. 10, 1956
COTILLION ROOM

8:00-9:00 **Registration**

9:00-9:05 **Call to Order**
Max L. Lichter, M.D., Member, Committee on Civil Defense, Council on National Defense, A. M. A., Detroit.

9:05-9:15 **Address of Welcome**
Harold C. Lueth, M.D., Chairman, Committee on Civil Defense, Council on National Defense, A. M. A., Evanston, Ill.

9:15-10:00 **A Critical Analysis and Evaluation of Civil Defense**
Honorable Chet Holifield, U.S. Congressman, 19th District of California, Chairman, Sub-Committee on Military Operations, Committee on Government Operations.

10:00-12:00 **How to Plan for Disaster—Panel Discussion**
Moderator—Charles P. Anderson, M.D., Deputy Commissioner, Medical Services, Department of Health, Detroit.

- (a) Casualty Estimates in Nuclear Warfare
  Lieut. Col. Arthur Steer, M.C., U. S. A., Deputy Commandant, Walter Reed Army Institute of Research, Washington, D. C.
- (b) Current Planning Concepts
  M. M. Van Sandt, M.D., Director, Medical Care Division, Health Office, Federal Civil Defense Administration, Battle Creek, Mich.
- (c) Management and Care of Mass Casualties
  Col. Joseph R. Shaeffer, M.C., U. S. A., Chief, Department of Atomic Casualties Studies, Walter Reed Army Institute of Research, Washington, D. C.
- (d) Hospital Planning for Disaster
  Jacques Cousin, Director, Oakwood Hospital, Dearborn, Mich.

12:00 Luncheon—Embassy Room

SATURDAY AFTERNOON—NOV. 10, 1956
COTILLION ROOM

2:00-5:00 **Workshop Session—CPX Operation (Paper Logistical Exercise)**
Presiding—C. P. Anderson, M.D.
The entire afternoon session will be devoted to group CPX sessions led by representatives of the Federal Civil Defense Administration. Conference participants will be divided into three working groups.

5:00 **Adjournment**

6:15-7:15 **Social Hour—Embassy Room**

SUNDAY MORNING—NOV. 11, 1956
COTILLION ROOM

9:00-10:30 **Reports of Workshop Sessions**
Presiding—Harold C. Lueth, M.D.

10:30-12:00 **Planning for Support—Panel Discussion**
Moderator—James H. Lade, M.D., Director, Office of Medical Defense, Department of Health, State of New York, Albany.

- (a) Resources Evaluation
  C. P. Anderson, M.D.
- (b) Federal Supplemental Support
  John M. Whitney, M.D., Director, Health Office, Federal Civil Defense Administration, Battle Creek, Mich.
- (c) Support Areas
  Frank F. Schade, M.D., Chief of Medical and Health Section of Los Angeles County and Cities Civil Defense Planning Board, Los Angeles.

12:00 **Luncheon—Embassy Room**
Mass Feeding and Integration of Services
Mrs. Kathryn G. Gasker, Executive Secretary, Disaster-Relief Committee, Academy of Medicine of Cleveland.

SUNDAY AFTERNOON—NOV. 11, 1956

2:00-3:30 **Mental Health Needs in Civil Defense and Disaster Planning—Symposium**
Ozro T. Woods, M.D., Mental Hygiene Consultant, Federal Civil Defense Administration, Dallas, Texas.
Calvin S. Drayer, M.D., Chairman, Committee on Civil Defense, American Psychiatric Association, Philadelphia.
Col. Albert J. Glass, M.C., U. S. A., Chief, Department of Neuropsychiatry, Walter Reed Army Hospital, Washington, D. C.

3:30-3:45 **The A. M. A. Council on National Defense**
Mr. Frank W. Barton, Secretary, Council on National Defense, A. M. A.

3:45-4:15 **Business Session—Adjournment**
Max L. Lichter, M.D.

PLAN HAWAIIAN TRIP AFTER SEATTLE MEETING

Physicians and their wives planning to attend the A.M.A. Clinical Session in Seattle, Nov. 27-30, are invited to take a Hawaiian vacation after the meeting. Ralph W. Neill, executive secretary of the Washington State Medical Association, has made arrangements for two different air cruises to Hawaii, direct from Seattle. Cruise highlights include air fare, accommodations at first-class hotels in Honolulu, sightseeing to the various islands, a yacht cruise of Pearl Harbor, a native "luau" and the services of experienced travel representatives. Details may be obtained from Mr. Neill, Washington State Medical Association, 1309 Seventh Ave., Seattle 1.

MEDICAL NEWS

ALABAMA

Surgeons Meeting.—The annual meeting of the Alabama division, International College of Surgeons, will be held at the Druid City Hospital, Tuscaloosa, Oct. 31. The medical profession is invited.

CALIFORNIA

Grant for Mental Health Research.—A $250,000 grant will be made by the Ford Foundation to Mount Sinai Hospital and Clinic (8712 Beverly Blvd., Los Angeles) for a portion of its mental health research program. Mount Sinai Hospital recently opened its 34-bed psychiatric inpatient department under direction of Dr. Steven D. Schwartz, chief of inpatient service of the department of psychiatry, assistant clinical professor in the department of nervous and mental diseases, College of Medical Evangelists, Los Angeles, and attending psychiatrist and neurologist at Los Angeles County Hospital (Medical Unit). The complete psychiatric program at Mount Sinai Hospital is directed by Dr. Franz Alexander, clinical professor of psychiatry at the University of Southern California School of Medicine, Los Angeles. Dr. Richard E. Renneker, formerly with the Chicago Institute of Psychoanalysis, was scheduled to join the staff in August as chief of outpatient service.

COLORADO

State Medical Election.—Officers of the Colorado State Medical Society include Dr. George R. Buck, Denver, president; Dr. Gatewood C. Milligan, Englewood, president-elect; Dr. C. Walter Metz, Denver, vice-president; Dr. James M. Perkins, Denver, constitutional secretary (three years); and Dr. William C. Service, Colorado Springs, treasurer (three years).

CONNECTICUT

Society News.—The Connecticut State Medical Society is planning to sponsor health exhibits at about 20 fairs this fall. The project, now in its fifth year, is conducted by county committees of the women's auxiliary in cooperation with the society's committee on rural health.

Fulbright Fellow.—Dr. David Weinman II, associate professor of microbiology at Yale University School of Medicine, New Haven, has been granted a Fulbright fellowship that will enable him to conduct research at Makerere College in Kampala, Uganda, East Africa. Dr. Weinman participated in the Harvard expedition to Peru in 1937 and the Harvard-American Foundation for Tropical Medicine expedition to Liberia in 1944. He has been a member of the Yale faculty since 1948.

State Aid to Nursing Education.—The Connecticut State Board of Examiners for Nursing has announced that 326 awards averaging $215 each were given to nursing students during the past year. The awards, totaling $70,000, were distributed under the provisions of section 1692C, chapter 213 of the Connecticut statutes, which provides "for a program of financial assistance and awards for nursing education in any duly accredited institution of learning in Connecticut." To be eligible for these awards a student nurse must have been a resident of the state for four years immediately before receiving the award and must agree to apply for a license as a nurse in Connecticut and to practice nursing in Connecticut immediately on graduation. The awards, according to the statute, "Shall not exceed the tuition charged by the institution together with the amount of educational fees, books, uniforms, board, and lodging."

Personal.—The University of Chicago recently conferred on Dr. John Rodman Paul, professor of preventive medicine, Yale University School of Medicine, New Haven, Conn., the honorary degree of doctor of science. The citation read, in part: "A meticulous investigator, whose fundamental studies have made valuable contributions to our understanding of the etiology, epidemiology, and control of a number of important contagious diseases."——Dr. John P. Bachman, who completed 30 years of service with the U. S. Army Medical Department in May, thereafter became the medical director of the Connecticut State Welfare Department, succeeding Dr. Harold F. Pierce, who became chief medical consultant in the department. Dr. Bachman will act as liaison with the Connecticut State Medical Society and the Connecticut Hospital Association and will administer those functions of the state welfare department concerned with the purchase of medical and hospital care.

DISTRICT OF COLUMBIA

Personal.—Dr. M. Wharton Young, professor of anatomy at Howard University College of Medicine, Washington, D. C., was appointed visiting professor of neuroanatomy at the Chicago Medical School for the summer quarter. Dr. Young was Fulbright Professor of Anatomy at Chiba University of Medicine in Japan in 1953.——At the commencement exercises June 3, Boston University bestowed the honorary degree of doctor of humane letters on Dr. Martha May Eliot, chief of the children's bureau, United States Department of Health, Education, and Welfare, Washington, D. C. Dr. Eliot has served as United States representative to the executive board of the United Nations Children's Fund since 1952 and was assistant director general of the World Health Organization, 1949-1951.——Dr. Jack Masur, assistant surgeon general and chief, Bureau of Medical Services, U. S. Public Health Service, delivered the annual Alphonse M. Schwitalla Lecture in hospital administration, sponsored by the department of hospital administration, at Firmin Desloge Hospital, St. Louis, May 15. His subject was "The Hospital Administrator and Patient Care." The lecture is given annually in honor of the Rev. Alphonse M. Schwitalla, president emeritus of the Catholic Hospital Association of the United States and Canada.——Dr. Mark S. Blumberg, formerly acting chief of the health conservation section of the U. S. Public Health Service in Washington, D. C., has joined the staff of Stanford Research Institute, Menlo Park, Calif., as an associate operations analyst in the economics division. Subjects Dr. Blumberg will consider in his new assignment include phases of health screening, industrial medicine, hospital planning, care of disaster casualties, medical education, and motor vehicle accident prevention.

FLORIDA

Course in Vectorcardiography.—A course in vectorcardiography will be given evenings at Mount Sinai Hospital of Greater Miami, Miami Beach, Nov. 5-9, by Dr. Arthur Girshman of New York City. Information may be obtained from the Medical Secretary, Mount Sinai Hospital, 4300 Alton Rd., Miami Beach, Fla.

Faculty Research Award.—The Chicago Medical School announces that, beginning with the ensuing academic year, a $1,000 award for research in medical and allied fields will be presented annually to a "promising faculty member" who has been recommended by the faculty research committee with final approval by the faculty council and board of trustees. The award is to be known as the Board of Trustees Faculty Research award.

Carlson Memorial Services.—Memorial services for Dr. Anton J. Carlson of the University of Chicago, who died Sept. 2, will be held in Pathology 117, Auditorium of Billings Hospital, 950 E. 59th St., Nov. 3, 2 p. m. Speakers will include Chancellor Lawrence A. Kimpton; John O. Hutchens, Ph.D., professor and chairman of the department of physiology; and Dr. Lester R. Dragstedt, Thomas D. Jones Professor and chairman of the department of surgery, University of Chicago School of Medicine, who will deliver the principal address.

Physicians are invited to send to this department items of news of general interest, for example, those relating to society activities, new hospitals, education, and public health. Programs should be received at least three weeks before the date of meeting.

ILLINOIS

Chicago

DeLee Lecture.—The 1956 Solomon Theron DeLee Lecture was delivered at the Albert Merritt Billings Hospital, Oct. 10, by Dr. Hans L. Kottmeier, associate professor, Royal Karolinska Institute, Stockholm, Sweden, on "The Treatment of Uterine Carcinoma at the Radiumhemmet."

Schiller Memorial Fund.—The Alfred A. Schiller Memorial Fund, which will provide an annual lectureship, is being established at the University of Illinois College of Medicine in honor of Dr. Schiller, assistant professor of physiology, who died April 21, 1955. Contributions to the fund may be sent in care of Dr. George E. Wakerlin, 1853 W. Polk St., Chicago 12.

Study of Combined Premedical and Medical Education.—Northwestern University Medical School has received a three-year $75,000 grant from the John and Mary Markle Foundation for study of a program to combine premedical and medical education. According to Dr. Richard H. Young, dean, a portion of a recent $300,000 grant from the Commonwealth Fund also will be used to support the study. The study, which will be conducted jointly by faculty members of the medical school, the college of liberal arts, and the graduate school, will attempt to provide one continuous program of education in basic sciences, humanities, and medicine, so that students would begin the new course on graduation from high school and, after seven or eight years, finish with the degree of doctor of medicine. Two problems to be solved in setting up the program will be (1) designing the courses so that a student can logically branch out into other fields allied to medicine if he desires to drop his training to be a physician and (2) designing the program so that graduates from other liberal arts colleges may enter the medical program at Northwestern.

Personal.—Dr. Harold S. Feinhandler, clinical associate in ophthalmology at the Chicago Medical School, has been promoted to the rank of associate on the Mount Sinai Hospital staff, which is affiliated with the school as a teaching hospital.—Dr. Samuel M. Feinberg, professor of medicine, Northwestern University Medical School, spoke at Meharry Medical College, Nashville, Tenn., June 5, at the celebration of the 80th anniversary of the founding of the college. His subject was "Allergy: 1956 Inven- ory."—Dr. Albert Dorfman, associate professor of pediatrics, niversity of Chicago School of Medicine, recently lectured at e first International Symposium on Rheumatic Fever, presented by the National Institute of Cardiology, the Mexican Society of Cardiology, and the Sociedad de Internos y Becarios del Instituto Nacional de Cardiologia, in Mexico City. His topics were "Ideas on the Etiology of Rheumatic Fever" and "The Metabolism of Mucopolysaccharides."—At the invitation of the Ministry of Education of Czechoslovakia, Dr. John F. Pick presented the guest paper, "The Meaning of the Human Face," at the first International Congress of Plastic Surgeons in Prague, Czechoslovakia, Sept. 27-29.—Dr. Frederick Plotke, chief, Public Health Service, Illinois Department of Public Welfare, has been appointed assistant professor of preventive medicine and public health at the Stritch School of Medicine of Loyola University.—At the 10th annual conference in Augusta, Ga., the Association for Physical and Mental Rehabilitation bestowed the John E. Davis award on Dr. Louis B. Newman, chief, physical medicine and rehabilitation service, Veterans Administration Research Hospital, for "distinguished leadership and outstanding service in the field of physical medicine and rehabilitation."

LOUISIANA

Society News.—Recently elected officers of the Louisiana Pathology Society include Dr. Rudolph J. Muelling Jr., New Orleans, president; Dr. Ulysses H. Stoer, Shreveport, La., vice-president; and Dr. Ralph M. Hartwell, New Orleans, secretary-treasurer.

Listeriosis in An Infant.—According to the U. S. Public Health Service, Dr. Joseph D. Martin, Louisiana Department of Health, has reported a case of listeriosis in a 2-week-old infant, who became ill with a temperature of 103 F (39.4 C). Examination revealed a slight infection of the eyes, conjunctivitis, and inflammation of the posterior pharynx; later the infant began to have tonic contractions. There was mild rhinorrhea and reddening and mild bulging of the tympanic membrane of the right ear with some exudate. The white blood cell count was 13,900 per cubic millimeter; the spinal fluid was cloudy, containing 3,280 cells. Listeria monocytogenes was cultured from spinal fluid obtained three days after the onset of illness. Gram-positive diplococci were cultured from the ear exudate, but L. monocytogenes was not found. Cultures of cervical exudate from the mother were negative. The sources of the infection had not yet been identified.

MASSACHUSETTS

Visiting Lecturer in Dental Medicine.—Dr. Bengt Olof Engfeldt, professor of pathology at Uppsala University, Sweden, has been named a visiting lecturer in the Harvard School of Dental Medicine in Boston. Dr. Engfeldt, who studies the life cycles of bone tissue and the diseases and injuries affecting its normal construction and reconstruction, is particularly concerned with the way in which bone tissue retains radioactivity and the effect this radiation may have on surrounding tissue, including the bone marrow. Dr. Engfeldt has served as visiting research worker at the School of Anatomy, Cambridge University, and the Biophysical Unit of King's College, London, and as associate professor of pathology at his alma mater, the Karolinska Institute at Stockholm University.

MINNESOTA

Personal.—Dr. William L. Benedict of Rochester, executive secretary-treasurer of the American Academy of Ophthalmology and Otolaryngology, has been appointed to the National Advisory Neurological Diseases and Blindness Council for a term of four years. He thus becomes one of 12 members of the council who advise the surgeon general on the research program of the National Institute of Neurological Diseases and Blindness.

McGraw Lecture.—The recent annual McGraw Lecture was delivered by Dr. James T. Priestley, professor of surgery, University of Minnesota Graduate School, Minneapolis-Rochester, whose topic was "Hyperfunctioning Lesions of the Adrenal Gland." The McGraw Lectureship was established in 1948 by the Detroit Surgical Association in honor of Dr. Theodore A. McGraw, a founder and first professor of surgery at the Detroit College of Medicine, now Wayne University College of Medicine, Detroit. The McGraw medal was awarded to Dr. Priestley and to Dr. Charles G. Johnston, Detroit, at the meeting.

Fifty-Year Club.—At the annual banquet of the Minnesota State Medical Association in Rochester, the following physicians were made members of the "50 Club": John F. Hendrickson, Gilbert L. Doxey, Ette L. Meyer, and Frederick C. Rodda, all of Minneapolis; Robert M. Burns, Harold J. Rothschild, O. William Holcomb, Andrew W. Hilger, and Ernest T. F. Richards, all of St. Paul; Samuel J. Hillis, Bradenton, Fla., and Henry G. Collie, St. Petersburg, Fla., both formerly of St. Paul; Edward L. Tuohy, Santa Barbara, Calif., formerly of Duluth; Winslow C. Chambers, Blue Earth; Arthur W. Ide, White Bear Lake; Archibald W. Graham, Chisholm; John W. Helland, Spring Grove; Johannes C. Jacobs, Willman; Herman Linde, Cyrus; Henry E. Nelson, Crookston; Oliver M. Porter, Atwater; Ludwig L. Sogge, Windom; Joseph D. Waller, Pine City; and Alexander M. Watson, Royalton.

MISSOURI

Hospital News.—In connection with their centennial festivities, the Sisters of Mercy of St. Louis have established a historical museum in a room attached to their convent at St. John's Hospital, 307 S. Euclid Ave., St. Louis. Dr. Alphonse McMahon is the hospital's chief of staff.

NEW YORK

Society News.—At the first meeting of the newly organized Westchester chapter of the American Federation for Clinical Research, Sept. 24 at White Plains Hospital, Dr. Dennison Young was elected president; Dr. Charles A. Bertrand, vice-president; and Dr. Alfred S. Dooneief, secretary-treasurer.

New Position at Albany College.—Dr. William P. Nelson III, chief of medical service, Veterans Administration Hospital, Albany, and assistant professor of medicine, Albany Medical College, has been named to the new administrative position of assistant dean and assistant director of postgraduate medical education at the medical college. He will collaborate with the director of postgraduate medical education, Dr. Frank M. Woolsey Jr., and be concerned with such undergraduate problems as admissions, health, curriculum, counseling, and internships and will also work in teaching and research and in the development of close rapport between Albany Hospital and the Veterans Administration Hospital.

Promoted to Professorships.—The State University of New York College of Medicine at Syracuse has announced the promotion to full professorship of Dr. Harry A. Feldman, chief, section of preventive medicine, and Drs. Paul A. Bunn and Eugene L. Lozner, department of medicine. Dr. Bunn, who came to the college of medicine as associate professor of medicine in 1947, has been consultant to the tuberculosis division of the U. S. Public Health Service and a member of the committee on research and education of the American Trudeau Society. He was president of the New York State Trudeau Society, 1953-1954. He has been affiliated with University Hospitals in Cleveland, the University of Michigan hospital in Ann Arbor, Cornell University hospital in New York, and the Veterans Administration. Dr. Feldman, who became associate professor of medicine at the college of medicine in January, 1949, was appointed chief of the section of preventive medicine when it was established in November, 1955. He had served as a research fellow at George Washington University School of Medicine, Washington, D. C., and at Harvard Medical School, Boston. He entered the Medical Corps of the Army in 1942 and, after separation from the service, was appointed a Senior Fellow in Virus Diseases of the National Research Council, conducting research in viral diseases of childhood at the Children's Hospital Research Foundation, Cincinnati. Dr. Lozner, who came to the college of medicine as associate professor in October, 1947, served as director of clinical laboratories at Syracuse Memorial Hospital from 1948 to 1952 and since 1948 has held the same position at University Hospital. For three years he has been chairman of the blood bank committee of the Onondaga County Medical Society. From 1941 to 1946 Dr. Lozner was on active duty in the U. S. Navy, and from 1946 to 1947 he was instructor in medicine at Harvard Medical School, Boston.

New York City

Study of Pancreatitis.—The University Hospital of the New York University–Bellevue Medical Center has received a John A. Hartford Foundation grant of $159,000 for a comprehensive study of pancreatitis in all its stages. Dr. J. William Hinton, director of the University Hospital department of surgery, will direct the project and will be assisted by Dr. L. Corsan Reid, professor of research surgery, New York University Post-Graduate Medical School, and Drs. George Mixter and Robert B. Pfeffer, who hold the rank of assistant attendingmen at University Hospital.

Course on Office Proctology.—Dr. Robert Turell and staff will give a course on office proctology Nov. 12-13 at the Mount Sinai Hospital in affiliation with Columbia University. The course, designed to acquaint the clinician with the important proctologic conditions that lend themselves to office diagnosis and treatment, will include demonstration of all diagnostic and various therapeutic procedures. The course (fee $50) will be repeated Feb. 18-19, 1957. For information address the Registrar for Postgraduate Medical Instruction, Mount Sinai Hospital, Fifth Avenue and 100th Street, New York 29.

Medical Art Exhibit.—A collection entitled "Ars Medica," including 85 rare pieces bearing on the teaching and practice of medicine, is on exhibit during October at the New York Academy of Medicine, 2 E. 103rd St. The exhibit is open to the public from 9:30 a. m. to 5 p. m. daily except Sundays (admission free). Among the prints are the Vesalius "Ninth Plate of Muscles"; Rembrandt's "Portrait of Dr. Ephraim Bonus"; Bellini's "Visit to the Plague Patient"; Eakins' original engraving of "The Gross Clinic"; Bosse's engraving of "The Confinement"; Winslow Homer's Civil War portrayal of the "Surgeon at Work During an Engagement"; Hogarth's "The Company of Undertakers"; and Toulouse-Lautrec's lithograph of the sick French premier Carnot.

Meeting of General Practice Group.—The seventh annual scientific assembly of the Nassau County chapter of the American Academy of General Practice will be held at the Garden City Hotel, Garden City, Nov. 7. The program, beginning at 10 a. m., will include the following presentations:

Hazards in Treatment of Acute Myocardial Infarction, Henry I. Russek, Staten Island.
Infectious Diseases: Basic Considerations with Respect to Their Pathogenesis, Diagnosis, and Management, Theodore E. Woodward, Baltimore.
Use of Antibiotics in Treatment of Infections, Ivan L. Bennett Jr., Baltimore.
Advances in Cardiac Surgery, Charles P. Bailey, Philadelphia.
Purpura, William Dameshek, Boston.
Roles of General Practitioner and Ophthalmologist, Adolph W. Vogel, Philadelphia.

Psychosomatic Forum.—The Psychosomatic Forum of New York City (American Psychosomatic Society) will meet in the Blumenthal Auditorium of Mount Sinai Hospital (Atran Laboratory Building entrance, Fifth Ave.), Oct. 30, 8:30 p. m. Dr. Robert Dickes, associate professor of psychiatry, State University of New York College of Medicine at New York City, Brooklyn, will serve as chairman for the following panel on "The Tranquilizers":

Psychiatric Implications of Tranquilizing Drugs, Paul H. Hoch, New York City.
Some Pharmacological Aspects of the Newer Psychiatric Agents, Murray E. Jarvik, New York City.
Psychodynamic Action of Chlorpromazine and Reserpine, Mortimer Ostow and Nathan S. Kline, New York City.

A collation will follow the program, which is open to all interested persons.

Dedicate Chair of Dermatology.—In ceremonies in the Bellevue Psychiatric Hospital Amphitheatre, the George Miller MacKee Chair of Dermatology and Syphilology was formally dedicated. Named as first incumbent was Dr. Marion B. Sulzberger, director of dermatology, New York Skin and Cancer Unit, a division of the Bellevue Medical Center's University Hospital, and chairman, department of dermatology and syphilology of New York University Post-Graduate Medical School and the College of Medicine. The chair was made possible through the will of the late Dr. MacKee, who founded "the most complete, self-contained department of dermatology in the United States, encompassing in its own premises separate divisions of histopathology, mycology, surgery, allergy and immunology, pharmacy, physical therapy, hematology, photography, etc. This department, at the Skin and Cancer Unit of New York University–Bellevue Medical Center, has now trained well over a thousand postgraduate students coming from all over the world." Dr. MacKee, author of the textbook "X-Rays and Radium in the Treatment of Diseases of the Skin," was editor from 1909 to 1918, with the assistance of his wife Katherine, of the *Journal of Cutaneous and Venereal Diseases,* the predecessor of the present *A. M. A. Archives of Dermatology.*

NORTH CAROLINA

Personal.—Dr. Charles Capers Smith, who for two years has been studying neurology as a teaching fellow at the University of North Carolina School of Medicine, Chapel Hill, left recently for London, England, to spend a year in neurology at the National Hospital, Queens Square.——Dr. George D. Penick, assistant professor, department of pathology, University of North Carolina School of Medicine, Chapel Hill, received a travel award of $500 to attend the 20th International Physiological Congress in Brussels, Belgium, from the Federation of American Societies for Experimental Biology. The award was made on the basis of his paper, "Studies on Inactivation of Antihemophilic Factor in Clotting Plasma Systems," which he was to present at the congress.

OHIO

Society News.—New officers of the Academy of Medicine of Cleveland include Dr. A. Macon Leigh, president; Dr. Thomas D. Kinney, president-elect; and Dr. Chester R. Jablonoski, vice-president.

University News.—Dr. Azad A. Katchian, a graduate of the American University of Beirut, Lebanon, has been appointed personnel health physician at the Ohio State University Health Center, Columbus, to replace Dr. William W. Davis, who has accepted the position of medical director at North American Aviation. Dr. Davis will remain as assistant professor of preventive medicine and will help develop the graduate programs in aviation medicine and occupational medicine. Dr. Katchian has been affiliated with Edward Sanatorium in Naperville, Ill., and West Suburban Hospital, Oak Park, Ill.

Survey to Evaluate Hospital Care.—Under a grant from the U. S. Public Health Service, a three-year survey to develop a method for evaluating a hospital in terms of good patient care is being undertaken at Ohio State University Hospital, Columbus, under the direction of Daniel Howland, assistant professor of industrial engineering. The $180,000 project will measure the quality of patient care in every aspect of hospital operation. It is anticipated that, through evaluation of the effects of proposed changes in personnel and facilities on patient care, a significant reduction in the cost of hospital operations, in both dollars and manpower, may result.

OKLAHOMA

Ball Park Telephone.—The Tulsa Oilers have installed a telephone in the grandstand at the ball park for the exclusive use of physicians during the baseball season. A desk, pads, and pencils have also been provided.

Society News.—The Oklahoma State Radiological Association recently elected Dr. Lucien M. Pascucci, Tulsa, president; Dr. Simon Pollack, Tulsa, vice-president; and Dr. Sol Wilner, Tulsa, secretary-treasurer.

Founders Day Clinic at Tulsa.—The Tulsa County Medical Society will present its fourth annual Founders Day Clinic, Oct. 31-Nov. 1 at Tulsa. The clinic will open with a dinner meeting at the Mayo at 6:30 p. m. Wednesday. Dr. S. Buford Word, professor of obstetrics and gynecology, Medical College of Alabama, Birmingham, guest speaker of the evening, will discuss "Reconstruction of the Vagina." On Thursday at the Blue Cross-Blue Shield Building, 1215 S. Boulder St., a clinical pathological conference will be conducted by Dr. Otto Saphir, professor of pathology, University of Illinois College of Medicine, Chicago. Other speakers will be Dr. Walton R. Akenhead, associate professor of medicine, and Dr. Laurence H. Strug, clinical professor of surgery, both of Louisiana State University School of Medicine, New Orleans. There will be no charge except for meals. The clinic is jointly sponsored by the Tulsa County Medical Society, the Oklahoma division of the American Cancer Society, the Tulsa Academy of General Practice, the Tulsa County Heart Association, and the Arthritis and Rheumatism Foundation of Eastern Oklahoma.

OREGON

Personal.—Life memberships in the Oregon State Medical Society have been awarded to Drs. Augustus B. Dykman and Eugene P. Steinmetz, both of Portland. Dr. Dykman has been a member of the state society since 1922 and Dr. Steinmetz since 1920.

PENNSYLVANIA

Surgical Meeting in San Francisco.—The Hawthorne Surgical Society of the Graduate School of Medicine, University of Pennsylvania, Philadelphia, held its annual meeting on Wednesday evening, Oct. 10 in San Francisco during the convention of the American College of Surgeons.

Dr. Chapman Honored.—Dr. Leroy E. Chapman, Warren, was recently honored at Warren General Hospital when the Warren County Medical Society presented him with a plaque for 50 years of service as a doctor. Dr. Chapman who has served in the senate of the Pennsylvania General Assembly since 1930, was reelected last year for his eighth term. He is author of a study of problems of the aging in Pennsylvania and is a member of the Pennsylvania Cancer Commission, the Joint State Government Commission, and the Pennsylvania Historical and Museum Commission. He holds a plaque awarded by the Pennsylvania medical society for distinguished medical legislation.

Personal.—At the 109th annual commencement exercises of the Hahnemann Medical College and Hospital of Philadelphia, June 14, Dr. Donald Guthrie, surgeon-in-chief of the Guthrie Clinic of the Robert Packer Hospital in Sayre, was awarded the honorary degree of doctor of humane letters, and Mr. Francis Boyer, president of Smith, Kline & French Laboratories, Philadelphia, received an honorary doctorate of laws.

Philadelphia

Phi Delta Epsilon Lecture.—The Sigma chapter of the Phi Delta Epsilon Fraternity at Temple University School of Medicine will hold its ninth annual lectureship at 4 p. m., Oct. 31, in the auditorium of the medical school. The guest speaker, Dr. Charles R. Rein, associate professor of clinical dermatology and syphilology, New York University Post-Graduate Medical School, New York, will discuss "The Detection and Clinical Importance of Biologic False Positivity in Serologic Tests for Syphilis."

Dr. Kern Honored.—A testimonial dinner was recently given for Dr. Richard A. Kern, head, department of medicine, Temple University Medical Center, by the heads of departments and the medical staff. He was honored also at a testimonial dinner at the Philadelphia Cricket Club. It was given by former residents who were on his service at the Temple University Hospital, who presented him with a silver tray. Dr. Kern, who was recently named president-elect of the American College of Physicians, is a retired rear admiral in the Medical Corps, U. S. Navy, and has served as chief of medicine at Temple since 1946.

University News.—A grant of $166,466.39 from the Samuel S. Fels Fund has been awarded to the Fels Research Institute at the Temple University School of Medicine for the 1956-1957 fiscal year. The money will support studies in cancer research and gastroenterology under the direction of Dr. Harry Shay.——At their annual donor dinner, May 3, the Brith Sholom Women presented a check for $20,000 to Dr. Madison B. Brown, executive vice-president of the Hahnemann Medical College and Hospital of Philadelphia, representing the group's continued support of the Brith Sholom Laboratory for Cardiovascular and Pulmonary Research. The year's donation brings to $110,000 the total given to the facility since its dedication five years ago.——Dr. John H. Gibbon Jr., director of surgical research at Jefferson Medical College since 1946, has been advanced to head of the department of surgery and to the Samuel D. Gross Chair of Surgery. Dr. Gibbon, a former president of the American Surgical Association and consulting surgeon to Pennsylvania Hospital and Philadelphia Veteran's Administration Hospital, pioneered the development of the heart-lung machine used to take over functions of these organs during heart operations. He will occupy the positions held since 1950 by the late Dr. Thomas A. Shallow, who died last December.——At the graduation exercises of the Temple University School of Medicine June 14, the invocation was read by the Rev. Jan Frederick Mittemeyer, who came from Dutch Guiana to see his son, Bernhard, graduate in the class of 125 members. Drs. Thomas M. Durant and Bernard J. Ronis, both faculty and hospital staff members, presented their sons, John R. Durant and Max L. Ronis, with their diplomas. The elder Ronis is also a graduate of the school (class of 1934). Three other fathers, all graduates of the school—Drs. Alphonse V. Clement Sr., Brooklyn, N. Y. (class of 1935), Charles W. Delp Sr., St. Clair, Pa. (class of 1924), and Joseph C. Donnelly Sr., Philadelphia (class of 1924)—saw their sons graduate together.

Personal.—Dr. Catherine Macfarlane, professor of gynecology, Woman's Medical College of Pennsylvania, was honored as "Woman of the Year" by the Brith Sholom Women at their annual donor dinner, where a plaque was presented to her for outstanding service in the general field of public welfare and human relations.——Dr. Thomas E. McGraw has been appointed Philadelphia plant medical director of the Exide Industrial Division, the Electric Storage Battery Company, to succeed Dr. Gilbert B. Meyers, now with Radio Corporation of America. Dr.

McGraw is a staff member of Frankford Hospital.——Robert C. Baldridge, Ph.D., assistant professor of physiological chemistry, Temple University School of Medicine, has been named a consultant to the medical division of the Oak Ridge (Tenn.) Institute for Nuclear Studies. Dr. Baldridge will give counsel in studies relating to the effect of hormones on amino acid metabolism and protein synthesis, currently in progress at the institute. ——Dr. Carroll R. Mullen, former national president of the Alumni Association of Jefferson Medical College of Philadelphia, has been appointed professor and head of the department of ophthalmology at the college. He succeeds Dr. Arno E. Town, who will continue in the private practice of ophthalmology in New York. Dr. Mullen is attending surgeon and executive surgeon at the Wills Eye Hospital and serves as a consultant in ophthalmology at the Philadelphia General Hospital, Thomas M. Fitzgerald Mercy Hospital, Darby, and the J. Lewis Crozer Homeopathic Hospital, Chester.——On June 13 the city council adopted a resolution commending Dr. Isidor S. Ravdin, the only civilian surgeon called in as a member of the medical team that performed President Eisenhower's abdominal operation. The resolution reads, in part: ". . . . Dr. Ravdin, educated in a Philadelphia medical school and a surgeon in Philadelphia hospitals, has had an illustrious career spanning nearly 40 years. . . . Dr. Ravdin's tireless activity has made him a leader within the medical profession, and has contributed greatly towards Philadelphia's reputation as a major medical center. . . ."——Dr. Arthur F. Seifer, associate in orthopedics, Temple University Medical Center, delivered the presidential address at the May 4 meeting of the Philadelphia Orthopedic Club.——Dr. Ward D. O'Sullivan, formerly associate professor of clinical surgery at Cornell University Medical College, New York, and associate attending surgeon at New York Hospital, is director of surgery at Misericordia Hospital, where he conducts the surgical residency program.——Dr. John P. Turner, a former police surgeon and member of the board of education, was honored at the regular meeting of the Philadelphia County Medical Society, May 23, in recognition of the completion of 50 years in the practice of medicine. Dr. Turner was 22nd president of the National Medical Association in 1921 and its distinguished service medalist in 1946.——Dr. Thomas M. Durant of the Temple University Medical Center recently participated in the Ventnor Foundation meeting in Wiesbaden, Germany, in behalf of the German Intern-Exchange Programs, an arrangement by which exchangees spend 13 months in Germany and America as rotating interns. Dr. Durant spoke on "Management of Congestive Heart Failure." Those attending the conference were alumni of the program and medical educators who have been active in its operation. The effort is independent of any government agency but is conducted with the cooperation of the U. S. State Department.

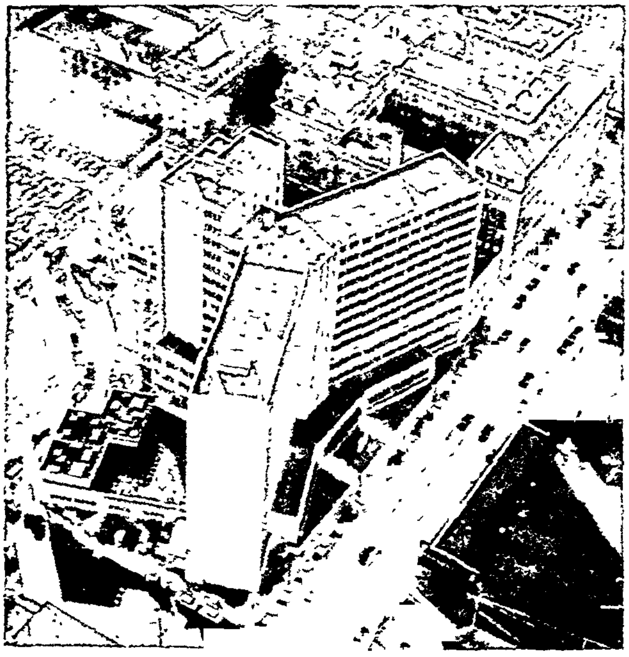
TENNESSEE

Society News.—Officers of the Tennessee Society of Pathologists include Dr. Frank C. Womack Jr., Nashville, president and councilor to the American Society of Clinical Pathologists; Dr. Chester K. Jones, Jackson, vice-president and president-elect; and Dr. George F. Bale, Memphis, reelected secretary-treasurer.

University News.—The University of Tennessee College of Medicine, Memphis, announces the following promotions: Drs. Garabed H. Aivazian, William J. Von Lackum, and Phineas J. Sparer, from assistant professor to associate professor in the department of psychiatry; Drs. William F. Murrah, department of ophthalmology, and Don L. Winfield, department of psychiatry, from instructor to assistant professor; Dr. Alvin J. Ingram, from assistant to assistant professor in the department of orthopedic surgery; and Drs. R. Beverly Ray and Moore Moore Jr., department of orthopedic surgery, and Drs. Henry J. Roberts and Margaret J. Halle, department of ophthalmology, from assistant to instructor.

Grants for Poliomyelitis Research.—The work of the Poliomyelitis Respiratory Center at Vanderbilt University Hospital, Nashville, will be supported during the coming year by a grant from the National Foundation for Infantile Paralysis of $54,724.74 that will be administered under the direction of Dr. O. Randolph Batson, associate professor of pediatrics. Research being conducted at the center includes studies of various breathing difficulties, the effects of prolonged bedrest, and complications associated with severe paralysis. An additional grant of $8,617 was made by the foundation for development of an iron lung that will adjust automatically to the patient's needs so that, through the muscle impulses he would normally use for breathing, he can control both the rate and depth of breathing with which the machine operates.

Baptist Memorial Addition.—The new Madison-East Building of Baptist Memorial Hospital, Memphis, erected and equipped at a cost of $8,250,000, adds nine patient floors and increases the capacity of the hospital to 800. The new building is so planned that it can be enlarged when necessary. According to Frank S. Groner, LL.D., administrator, a 25-year plan calls for 1,400 beds. The entire building is air-conditioned. Nine of the 13 floors are for hospital rooms, with a special penthouse for the radioisotope laboratory. The third floor has 19 operating rooms in which outlets for oxygen and anesthetics on two walls permit the surgeon to operate from either side of the room. Baptist Hospital has 1,500 employes, including 265 student nurses, 20 interns, and 21 residents. Its 400 doctors contributed more than $200,000 for the Madison-East Building.



Madison-East Building, forefront, flanked at right by original Baptist Memorial Hospital, in rear of which is nurses' dormitory.

Research Grants.—The University of Tennessee College of Medicine, Memphis, has been awarded a grant of $9,720 by the Institute of Arthritis and Metabolic Diseases of the U. S. Public Health Service to establish a special training program in the field of rheumatology. The program director for the project, which will be in the department of medicine of the City of Memphis Hospitals, is Dr. I. Frank Tullis, chief, division of medicine.——The National Heart Institute of the U. S. Public Health Service, the Atomic Energy Commission, and the Memphis Heart Association have awarded Nicholas R. DiLuzio, Ph.D., instructor in physiology, research grants totaling $28,712 for support of his studies on the harmful effects of exposure to radiation and his investigation of fat metabolism.——Dr. Edward H. Storer, assistant professor of surgery, has been given a $10,350 research grant by the National Cancer Institute of the U. S. Public Health Service for a project to produce stomach cancer in experimental animals and study the disease process. ——Dr. Robert C. Rendtorff, assistant professor of preventive medicine, has been awarded a $33,623 three-year research grant for the study of virus and parasite relationships by the National Institute of Allergy and Infectious Diseases of the U. S. Public Health Service.

TEXAS

Symposium on Carcinoma of the Breast.—The University of Texas M. D. Anderson Hospital and Tumor Institute, in conjunction with the University of Texas Postgraduate School of Medicine and the Texas division, American Cancer Society, will present a symposium on management of carcinoma of the breast in the Main Auditorium of the hospital, Houston, Nov. 9-10. The symposium will constitute a 10-hour course of formal teaching for American Academy of General Practice credit. The Friday morning program, 9 a. m., will consist of a review of "The Present Knowledge of the Spread of Cancer" by Dr. R. Lee Clark Jr., Houston; "Treatment Policies Based on Present Concepts" by Dr. Edgar C. White, Houston; and "Presentation of Cases Covering the Spectrum of Problems of Primary Treatment," with Drs. Clark, White, Gilbert H. Fletcher, Everett Lewis, and William O. Russell, Houston, serving on the panel. The afternoon meeting will be opened by Dr. Melvin A. Casberg, vice-president in charge of medical affairs, University of Texas, Austin, who will discuss "Surgical Treatment of Cancer of the Breast," which will be followed by presentation of "Present Concepts of Radiotherapy in Breast Cancer" by Dr. Fletcher. The afternoon program will be concluded by presentation of cases to illustrate problems of management of recurrences in local and regional areas. A get-acquainted hour, 5:30 p. m. at the Doctors' Club, will precede dinner at 7, when Dr. Ian G. Macdonald, associate clinical professor of surgery, University of California at Los Angeles School of Medicine, will speak on "Statistics in Breast Cancer." Dr. Macdonald will open the Saturday morning program with "Hormonal Management of Late and Disseminated Carcinoma of the Breast," which will be followed by presentation of cases.

WEST VIRGINIA

Politics.—The following physicians were elected at the May primary as members of county boards of education: Dr. E. Burl Randolph, Clarksburg, Harrison County (reelected); Dr. William P. Bradford, Moundsville, Marshall County (reelected); Dr. James W. Stokes, Hinton, Summers County (reelected); Dr. Richard F. Miller, Paden City, Wetzel County; and Dr. Paul L. McCuskey, Parkersburg, Wood County. Dr. Ward Wylie of Mullens was nominated on the Democratic ticket to succeed himself as a member of the West Virginia Senate from the Ninth Senatorial District, and Dr. Thomas G. Matney of Peterstown is the Democratic nominee to succeed himself as a member of the House of Delegates from Monroe County. Dr. James A. Rusmisell of Buckhannon was elected delegate from the Third District to the Republican National Convention, and Dr. Ward Wylie was named alternate delegate to the Democratic National Convention. Dr. William E. Neal of Huntington was nominated on the Republican ticket for representative in Congress from the Fourth Congressional District. Dr. Clinton W. Stallard of Montgomery received the nomination on the Democratic ticket for county commissioner in Fayette County, and Dr. John M. Cofer of Bergoo was nominated on the Democratic ticket for the same office in Webster County.

WISCONSIN

Society News.—The Wisconsin Society of Internal Medicine recently elected Dr. Karl H. Doege, Marshfield, president; Dr. Robin N. Allin, Madison, vice-president; and Dr. Paul G. LaBissoniere, Milwaukee, secretary-treasurer.

GENERAL

Course on Diagnostic Radiology.—The University of Wisconsin Medical School, Madison, will offer a postgraduate course (fee $20) entitled "Diagnostic Radiology," Nov. 6-8, under the direction of Dr. Lester W. Paul of the department of radiology. The course, designed especially for the general practitioner, is not confined to registrants in Wisconsin. Those interested may contact Dr. Robert C. Parkin, Assistant to the Dean, 418 N. Randall Ave., Madison, Wis.

Neurological Surgeons Meet in Chicago.—The sixth annual meeting of the Congress of Neurological Surgeons will take place at the Palmer House, Chicago, Nov. 1-3. The theme of the program is centered on the pituitary gland, its ophthalmologic, endocrine, and surgical aspects. Dr. Wilder G. Penfield, Montreal, Canada, the principal guest speaker, will discuss the function of the temporo-Sylvian fissure and will present a historical sketch, "Dawn of Medicine in the Aegean." Inquiries should be directed to the office of the Secretary-Treasurer, Dr. Philip D. Gordy, 1007 Delaware Ave., Wilmington, Del.

Cardiac Conference.—The fifth Western Cardiac Conference will be held at the Cosmopolitan Hotel, Denver, Nov. 5-10. The first three days will be devoted to sessions on clinical electrocardiography at the Veterans Administration Hospital. The last three days will be concerned with sessions on recent advances in cardiovascular disease, held at the Cosmopolitan Hotel. The sponsoring organizations are the Colorado Heart Association, the University of Colorado Medical Center, the Veterans Administration Hospital, the Fitzsimons Army Hospital, and the Colorado State Department of Public Health.

Tropical Medicine Society.—The American Society of Tropical Medicine and Hygiene will hold its fifth annual meeting at the Jung Hotel, New Orleans, Oct. 31–Nov. 3, under the presidency of Asa C. Chandler, Ph.D., Houston, Texas. The 21st annual Charles Franklin Craig Lecture, "The Role of Pharmacology in Determining the Rational Use of Therapeutic Agents," will be presented Wednesday at 2 p. m. by Leon H. Schmidt, Ph.D., Cincinnati. Norman R. Stoll, Sc.D., New York, will serve as moderator for a symposium on helminthic infections as the cause of disability and disease Thursday, 2 p. m. The dinner session will be held Friday at 7 p. m., when presentation of the Walter Reed medal will precede the presidential address, "The Interrelations of Nutrition and Infectious Diseases in the Tropics" by Dr. Chandler. In all, 87 papers are scheduled for presentation. Scientific exhibits will be on display.

Cancer Seminar.—The Southeastern States Cancer Seminar will be held at the George Washington Hotel in Jacksonville, Fla., Nov. 7-8 under the sponsorship of the Duval County Medical Society and the auspices of the Florida division of the American Cancer Society, the Florida State Board of Health, and the department of medicine of the Graduate School of the University of Florida. There will be no registration fee. The following panel discussions have been scheduled:

Management of Carcinoma of the Breast, Everett D. Sugarbaker, Jefferson City, Mo., Chairman.
Female Genital Neoplasm, Other Than Carcinoma of the Cervix, Willard M. Allen, St. Louis, Chairman.
Diagnosis and Treatment of Carcinoma of the Colon and Stomach, Michael R. Deddish, New York, Chairman.
Tumors of the Skin and Subcutaneous Tissue, George C. Andrews, and George T. Pack, New York.
Tumors of the Head and Neck, James E. Scarborough, Emory University, Ga., Chairman.

Society Election.—Newly elected officers of the Biological Photographic Association include Mr. H. Lou Gibson, Rochester, N. Y., president; Mr. Leo C. Massopust Sr., Milwaukee, vice-president; Miss Jane H. Waters, New York, secretary; and Mr. Albert Levin, Pittsburgh, treasurer.

Memorial Fund for Medical Research.—Between Nov. 4, 1955, and May 21, 1956, the Jane Coffin Childs Memorial Fund for Medical Research, 333 Cedar St., New Haven 11, Conn., appropriated $390,734 for support of cancer research projects and fellowships.

Atomic Scientists Available for Lectures.—The U. S. Atomic Energy Commission, the Oak Ridge National Laboratory, and the Oak Ridge Institute of Nuclear Studies announce that 102 scientists from Oak Ridge laboratories will be available to lecture, conduct seminars, and participate in colloquiums on request at universities throughout the country. A brochure listing the 102 speakers and the 165 different lecture subjects may be obtained by writing the Chairman, University Relations Division, Oak Ridge Institute of Nuclear Studies, P. O. Box 117, Oak Ridge, Tenn.

New Scientific Director of Multiple Sclerosis Society.—Dr. Thomas L. Willmon, for the past five years executive officer of the Navy's medical research laboratory at Bethesda, Md., has been appointed director of the medical and scientific department of the National Multiple Sclerosis Society, succeeding Frederick

L. Stone, Ph.D., who has assumed his duties in Washington as technical analyst and staff advisor for the U. S. Public Health Service extramural research and training programs. Dr. Willmon has conducted research in respiratory and cardiovascular physiology and has supervised basic medical research while serving in administrative posts in the Naval Medical Corps. In accepting the directorship, Dr. Willmon is leaving the naval service after 25 years, holding the rank of captain.

Kenny Foundation Scholarships.—The Sister Elizabeth Kenny Foundation announces a program of postdoctoral scholarships to promote work in the field of neuromuscular diseases, designed for scientists at or near the end of their fellowship training in either basic or clinical fields concerned with the problem of neuromuscular diseases. Kenny foundation scholars will be appointed annually. Each grant will provide a stipend for a five-year period at the rate of $5,000 to $7,000 a year depending upon the scholar's qualifications. Candidates from medical schools in the United States and Canada will be eligible. Information may be obtained from Dr. Edgar J. Huenekens, Medical Director, Sister Elizabeth Kenny Foundation, 2400 Foshay Tower, Minneapolis 2.

Educational Foundation.—The University Club (1 W. 54 St., New York 19) recently announced the formation of the Educational Foundation of the University Club, Inc. The purposes of the foundation include the receipt and administration of funds exclusively for scientific, literary, educational, and charitable purposes; the granting of scholarships, fellowships, or other forms of voluntary financial assistance to worthy students, teachers, and organizations duly established to carry on educational functions; the fostering, encouragement, and conduct of scientific, literary, or educational research; and the granting of funds for such research and study. The foundation will be operated on a nonprofit basis. Contributions (tax deductible) should be sent in care of Mr. Duncan R. Linsley, Educational Foundation of the University Club, Inc.

Grants to Medical Schools.—The Commonwealth Fund (1 E. 75th St., New York 21) announces unrestricted grants of $4,850,000 to seven university medical schools, bringing to a total of $12,600,000 the amount of such gifts to medical schools made by the fund since November, 1955. This is in addition to the sums expended for specific medical education projects during the fiscal year 1955-1956. Grants of one million dollars each were made to the Johns Hopkins University School of Medicine, Baltimore, and Stanford University School of Medicine, Stanford University–San Francisco; $750,000 to the University of Rochester (N. Y.) School of Medicine & Dentistry; $600.000 to Boston University School of Medicine; and $500.000 to each of the following: Albany (N. Y.) Medical College of Union University, George Washington University School of Medicine, Washington, D. C., and the University of Pennsylvania School of Medicine, Philadelphia.

Ford Foundation Grants to Medical Schools.—The Ford Foundation, New York, has announced grants totaling $21,750,000 to strengthen instruction in the 44 privately supported medical schools in the United States. The grants are in the amount of $500,000 to each of 43 four-year institutions and $250,000 to the two-year medical school at Dartmouth College, Hanover, N. H. They were authorized on the recommendations of a special advisory committee headed by Lee A. DuBridge, Ph.D., president of the California Institute of Technology, Pasadena. The foundation set up the advisory committee to develop plans for distributing 90 million dollars that the foundation appropriated last December to aid the instructional programs of the private medical schools. The grants are to be held by the recipient institutions as invested endowment for at least 10 years. During this time the income from the endowment may be expended for instructional purposes. Excluded from purposes of the grants are construction and research needs. After a 10-year period the medical schools will be free to use the principal sum as well as the endowment income.

CANADA

Gross Memorial Lecture.—The 19th annual Louis Gross Memorial Lecture, under the auspices of the Montreal Clinical Society, will be held in the Main Auditorium, Nurses' Residence, Jewish General Hospital, Montreal, Nov. 1, 8:30 p. m. Dr. Henry K. Beecher, Dorr Professor of Research Anaesthesia, Harvard Medical School, Boston, will discuss "New Work on Pain and Pain-Relieving Agents."

LATIN AMERICA

Seminar on Diarrheal Diseases.—The government of Chile will sponsor the first of a proposed series of intercountry seminars on prevention, diagnosis, and treatment of diarrheal diseases in childhood to be organized by the Pan-American Sanitary Bureau, Regional Office of the World Health Organization. The seminar, to be held in Santiago, Nov. 5-10, will bring together public health administrators, specialists in the field of maternal and child health, pediatricians, sanitary engineers, public health nurses, epidemiologists, bacteriologists, and others. It is scheduled to develop concrete proposals for program planning and specific techniques for diarrheal disease control.

CORRECTION

Aryl Sulfonylureas.—In the article by Drs. R. H. Unger and J. W. Davidson Jr. in The Journal Sept. 29, 1956, page 449, left-hand column, line 14, the word "tolbutamide" is in error. It should have been "carbutamide."

EXAMINATIONS AND LICENSURE

American Board of Anesthesiology: *Part I.* Various locations, July 19. Final date for filing application is Jan. 19. Sec., Dr. Curtiss B. Hickcox, 80 Seymour St., Hartford 15, Conn.

American Board of Internal Medicine: *Subspecialties. Cardiovascular Disease.* Chicago, Nov. 30. Final date for filing application was June 1. *Gastroenterology.* Philadelphia, April 5-6. Final date for filing application is March 1.

American Board of Neurological Surgery: Examination given twice annually, in the spring and fall. In order to be eligible a candidate must have his application filed at least six months before the examination time. Sec., Dr. Leonard T. Furlow, Washington University School of Medicine, St. Louis 10.

American Board of Obstetrics and Gynecology: *Part I.* Various cities of the United States, Canada, and military centers outside the Continental United States, Feb. 1. Candidates must submit case reports to the office of the Secretary within thirty days of being notified of thei religibility to Part I. *Part II.* Chicago, May 16-25. Request for reexamination in Part II must be received prior to Feb. 1. Sec., Dr. Robert L. Faulkner, 2105 Adelbert Road, Cleveland 6, Ohio.

American Board of Ophthalmology: *Written.* Jan. 21. Final date for filing application was July 1. *Oral.* New York, May 23-27; Chicago, Oct. 7-11. Sec., Dr. Merrill J. King, Box 236, Cape Cottage Branch, Portland 9, Maine.

American Board of Orthopaedic Surgery: *Oral. Part II.* Chicago, January 1957. Final date for filing application was Aug. 15. Sec., Dr. Sam W. Banks, 116 South Michigan Ave., Chicago 3.

American Board of Pediatrics: *Oral. Part II.* San Francisco, Dec. 7-9. Sec., Dr. John McK. Mitchell, 6 Cushman Road, Rosemont, Pa.

American Board of Physical Medicine and Rehabilitation: *Parts I and II.* New York City, June 8-9. Final date for filing application is March 1. Sec., Dr. Earl C. Elkins, 200 First St., S.W., Rochester, Minn.

American Board of Preventive Medicine: *Oral and Written. Public Health.* Philadelphia, Nov. 8-10. Sec., Dr. Ernest L. Stebbins, 615 N. Wolfe St., Baltimore, Md.

American Board of Psychiatry and Neurology: *Oral.* New York, Dec. 10-11 and New Orleans, Mar. 18-19. Final date for filing application is Sept. 10. Sec., Dr. David A. Boyd, Jr., 102-110 Second Ave., S.W., Rochester, Minn.

American Board of Radiology: Tampa, April 1-6. Final date for filing application is Jan. 1. Sec., Dr. B. R. Kirklin, Kahler Hotel Bldg., Rochester, Minn.

American Board of Surgery: *Part I.* Various centers throughout the United States and in certain military centers abroad, Oct. 31. *Part II.* New Haven, Nov. 19-20; Kansas City, Kan., Dec. 10-11; Los Angeles, Jan. 14-15; San Francisco, Jan. 17-18; Houston, Feb. 18-19; Nashville, Mar. 11-12; Boston, April 8-9, and New York, June 10-11.

American Board of Urology: *February 1957.* Sec., Dr. William Niles Wishard, 1711 N. Capital Ave., Indianapolis 7.

Board of Thoracic Surgery: *Written.* Various centers throughout the country, February 1957, and the closing date for registration is Dec. 1, 1956. Sec., Dr. William M. Tuttle, 1151 Taylor Ave., Detroit 2.

GOVERNMENT SERVICES

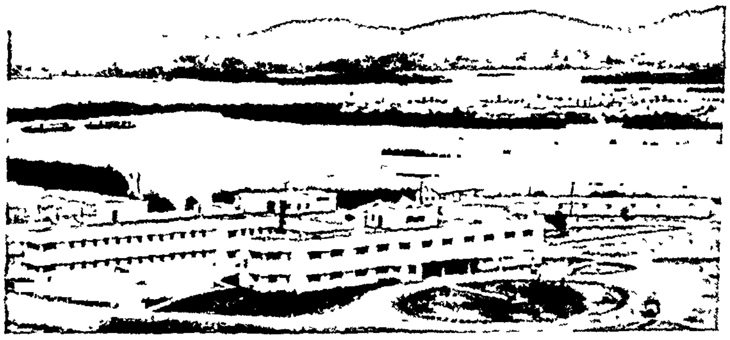
ARMY

Changes in Surgical Departments.—Lieut. Col. Curtis P. Artz, commander of the Surgical Research Unit at Brooke Army Medical Center, Fort Sam Houston, Texas, has left the military service to become professor of surgery at the University of Mississippi in Jackson. Colonel Artz entered the Army Medical Corps in 1948. He has been associated with the research unit at Brooke Army Medical Center for the last six years.

Col. Warner F. Bowers has arrived at the Tripler Army Hospital in Honolulu Hawaii, where he will be chief of the department of surgery, succeeding in that position Col. George Beatty, who has been assigned as chief of the department of surgery at the Valley Forge Army Hospital, Phoenixville, Pa.

NAVY

New Hospital at Guantanamo Bay.—At dedication ceremonies Sept. 18, 1956, Rear Adm. Bartholomew W. Hogan, surgeon general, accepted a new naval hospital for the medical department at Guantanamo Bay, Cuba. Having complete facilities for 100 bed patients and using the most modern construction materials, the new hospital will be air-conditioned throughout, the first naval hospital to be so equipped. At a cost of about $2,500,000, the new unit will replace the old wooden building used for many years. It will provide the latest medical facilities and care for naval personnel and their dependents stationed on the island. Capt. Lyle A. Newton, M.C., is the present commanding officer.



New naval hospital at Guantanamo Bay, Cuba (official U. S. Navy photograph).

Officials of various bureaus and offices of the Navy and the Department of Defense and representatives of the Army and Air Force participated in the dedication ceremonies. The hospital overlooks one of the most beautiful and best harbors in the world.

Reserve Officers Transfer to Regular Navy.—The following Naval Reserve medical officers have recently been commissioned in the Medical Corps of the regular Navy: Commander V. E. Seibert and lieutenants M. C. Shea Jr., J. F. Wurzel, H. O. Kretzschmar, J. A. Coulter, L. H. Seaton, Paul D. Mozley, A. A. McNitzky, H. R. Houston, L. N. Cahill, T. J. Grause, J. S. Garrison, and E. L. Bingham.

VETERANS ADMINISTRATION

New Advisory Committee Members.—Four new members have accepted appointments to the VA Special Medical Advisory Group as replacements for former members. The new members are Dr. Charles D. Shields, director, department of physical medicine and rehabilitation, Georgetown University, Washington, D. C., who replaces Dr. Donald A. Covalt, New York, whose membership has expired; Dr. Howard P. Rome, department of psychiatry, Mayo Clinic, Rochester, Minn., who replaces Dr. David A. Boyd Jr., department of psychiatry at the same clinic, whose five-year tenure has expired; Dr. Shields Warren of the Cancer Research Institute, Boston, who replaces Dr. Robert A. Moore, University of Pittsburgh, whose term has expired; and Mrs. Marion S. Bailey, associate director, National League for Nursing, New York City, who replaces Mrs. Elmira B. Wickenden, of Bronxville, N. Y., who has resigned.

This group meets quarterly to advise the administrator of veterans affairs and the chief medical director on the VA medical program.

PUBLIC HEALTH SERVICE

Advisory Committee Study to Help Hospitals.—A government advisory committee has been appointed to study and develop methods of adapting hospital facilities and services more closely to the varying needs of patients. Its objective is to help hospitals improve care and reduce costs, particularly for patients who need only limited services. Appointment of the committee was announced by Marion B. Folsom, Secretary of Health, Education, and Welfare.

The committee will review information on current practices and facilities and develop tentative recommendations for the design and organization of hospital units more closely related to the specific needs of patients, according to the severity of their illness or disability. The committee also will study ways in which hospital units can help provide effective services to some patients in their homes.

Dr. Russell Nelson, director, Johns Hopkins Hospital, Baltimore, will be the chairman. Other members of the advisory committee are Ray E. Brown, superintendent, University Clinics, University of Chicago, retiring president of the American Hospital Association; Robert Elman, M.D., department of surgery, School of Medicine, Washington University, St. Louis; Charles G. Roswell, hospital accountant, Montclair, N. J.; Ruth Sleeper, R.N., director, School of Nursing and Nursing Service, Massachusetts General Hospital, Boston; and Marion J. Wright, director, Jennings Memorial Hospital, Detroit.

Funds to Aid Teachers' Careers.—The Public Health Service's National Institute of Neurological Diseases and Blindness announces that funds are being made available to medical schools to strengthen existing clinical programs in advanced training in ophthalmologic and otologic diseases. The purpose is to stimulate the interest of more young physicians and scientists in careers as teachers and investigators in this field. Training grants also are available to basic science departments to expand postdoctoral training programs in the neurological sciences. Information may be obtained from the Chief, Extramural Programs, National Institute of Neurological Diseases and Blindness, National Institutes of Health, Bethesda 14, Md.

Research on Air Pollution.—Twelve grants for research on air pollution were announced Sept. 14 by Dr. Leroy E. Burney, surgeon general of the Public Health Service. The grants total $318,568. Six of the grants, totaling $177,548, are for new projects. The remaining six grants, amounting to $141,020, will continue support of projects already under way. These grants make a total of 32 that have been awarded since July, 1955, when air-pollution research was made a responsibility of the Public Health Service. All told, $780,137 has now been allocated to agencies, institutions, and individuals outside the federal government for such investigations.

DEATHS

Kimbrough, James Claude ⊕ Colonel, U. S. Army, retired, Silver Spring, Md.; born Nov. 5, 1887; Vanderbilt University School of Medicine, Nashville, Tenn., 1916; specialist certified by the American Board of Urology; member of the American Urological Association; fellow of the American College of Surgeons; entered the military service July 20, 1917; retired Aug. 31, 1948; since 1921 served almost exclusively as chief urologist at various Army hospitals; during World War II chief of the professional services division in the office of the chief surgeon of the European Theater of Operations; in 1945-1946, served as commanding officer of the Convalescent Hospital, Percy Jones Hospital Center, at Fort Custer, Mich.; awarded the Legion of Merit in 1945; later was chief of the urologic section, Walter Reed Army Hospital, Washington, D. C., and consultant in urology to the surgeon general, for liaison between the Army and the American Board of Urology; died Aug. 19, aged 68, of cancer of lung with metastasis.

O'Donnell, Alfred ⊕ Ellsworth, Kan.; born in 1873; University Medical College of Kansas City, Mo., 1900; member of the House of Delegates of the American Medical Association in 1925, 1926, and 1927; member of the founders' group of the American Board of Surgery; past-president of the Kansas Medical Society; fellow of the American College of Surgeons; member of the state board of health; for many years a member and for a time president of the school board; charter member and past-president of the Ellsworth Lions Club; for many years physician for the Union Pacific Railroad; served on the staff of the Ellsworth County Veterans Memorial Hospital, where he died June 26, aged 83, of pulmonary embolus and Parkinson's disease.

Rahman, Lincoln ⊕ Beverly Hills, Calif.; born in New York City Feb. 12, 1903; Cornell University Medical College, New York City, 1932; specialist certified by the American Board of Psychiatry and Neurology; member of the American Psychoanalytic Association and the American Psychiatric Association; assistant clinical professor of psychiatry at University of Southern California School of Medicine, Los Angeles; formerly associated with the U. S. Public Health Service Reserve; secretary of the Southern California branch, American Psychiatric Association, and vice-president of the Los Angeles Psychoanalytic Society; attending psychiatrist, Los Angeles County Hospital, Los Angeles; died Aug. 11, aged 52, of injuries received in an automobile accident.

Newburgh, Louis Harry, Valley Center, Calif.; born in Cincinnati in 1883; Harvard Medical School, Boston, 1908; professor emeritus of clinical investigation in internal medicine at the University of Michigan Medical School, Ann Arbor, where he joined the faculty in 1916; on the faculty of his alma mater from 1912 to 1916; specialist certified by the American Board of Internal Medicine; member of the American Society for Clinical Investigation; fellow of the American College of Physicians; the recipient of a certificate of merit for services in the Office of Strategic Research and Development during World War II; secretary of the special medical examining board during World War I; died July 17, aged 73.

Riter, Kersey Clyde ⊕ Salt Lake City; born in Logan, Utah, Dec. 8, 1906; Northwestern University Medical School, Chicago, 1937; specialist certified by the American Board of Otolaryngology; member of the American Academy of Ophthalmology and Otolaryngology, fellow of the American College of Surgeons; interned at the Passavant Memorial Hospital in Chicago; served a residency at the New York Post-Graduate Medical School and Hospital in New York City; veteran of World War II; served as a missionary in Switzerland; on the courtesy staffs of Dr. W. H. Groves Latter-Day Saints and St. Mark's hospitals; died July 23, aged 49.

Bardeleben, Walter, New York City; Friedrich-Wilhelms-Universität Medizinische Fakultät, Berlin, Prussia, Germany, 1919; member of the Medical Society of the State of New York; died in the Memorial Center for Cancer and Allied Diseases June 27, aged 65, of carcinoma of the pancreas with metastases.

Becker, Charles Nicholas ⊕ Chicago; Chicago College of Medicine and Surgery, Chicago, 1913; served on the faculty of his alma mater; died in the Augustana Hospital Aug. 15, aged 72, of carcinoma of the pancreas.

Cinberg, Morris, New York City; University of the South Medical Department, Sewanee, Tenn., 1899; an associate member of the American Medical Association; died Aug. 10, aged 81, of cerebral vascular accident, arteriosclerosis, and congestive heart failure.

Easly, Philip Howard, Elyria, Ohio; St. Louis University School of Medicine, St. Louis, 1954; interned at the U. S. Naval Hospital in St. Albans, N. Y.; formerly a resident at St. John's Hospital in Cleveland; died July 20, aged 32.

Gardner, John Gould ⊕ Columbia, Miss.; Medical Department of Tulane University of Louisiana, New Orleans, 1912; fellow of the American College of Surgeons; died Aug. 13, aged 76.

Graebner, Herbert ⊕ New York City; Milwaukee Medical College, Milwaukee, 1912; veteran of World War I; specialist certified by the American Board of Otolaryngology; member of the American Laryngological, Rhinological and Otological Society; formerly on the faculty of Cornell University Medical College; served on the staffs of the Manhattan Eye, Ear and Throat Hospital, New York Hospital, and the Willard Parker Hospital; died July 17, aged 66, of carcinoma of the stomach.

Gram, Gunnar, Geneva, Wis.; Chicago Medical School, Chicago, 1927; veteran of the Spanish-American War; died April 26, aged 76, of congestive heart disease and arteriosclerosis.

Hallowell, Albert V., Commander, U. S. Navy, Ocala, Fla.; born in Philadelphia Jan. 5, 1901; Hahnemann Medical College and Hospital of Philadelphia, 1924; veteran of World War II; active duty in the regular U. S. Navy began July 21, 1950; attached to the U. S. Navy Bureau of Medicine in Washington, D. C.; served as associate professor of otorhinology at his alma mater; formerly on the staff of the Hahnemann Hospital in Philadelphia; died in the U. S. Naval Hospital, Bethesda, Md., July 27, aged 55, of carcinoma of the bladder.

Hambly, Scott B., Morrice, Mich,; Michigan College of Medicine and Surgery, Detroit, 1897; died June 29, aged 84, of carcinoma of the bladder and prostate.

Holyfield, H. N. ⊕ Brandon, Miss.; Gate City Medical College, Texarkana, Texas, 1906; died July 26, aged 77.

Jackson, Jeremiah, Evansville, Ind.; Medical College of Indiana, Indianapolis, 1897; died in St. Mary's Hospital April 26, aged 86, of fractured pelvis as the result of a fall and coronary insufficiency.

Jackson, Norborn Herbert, Dardanelle, Ark.; Arkansas Industrial University Medical Department, Little Rock, 1901; died July 10, aged 80.

Johnson, Hal Glenn, Dundee, Miss.; Vanderbilt University School of Medicine, Nashville, Tenn., 1911; past-president of the Tunica County Medical Association; died Aug. 17, aged 68.

Jones, Dudley Watson ⊕ Jackson, Miss.; Medical Department of Tulane University of Louisiana, New Orleans, 1900; past president and formerly member of the council of the Mississippi State Medical Association; served as a member of the council of the Southern Medical Association; died July 27, aged 86.

⊕ Indicates Member of the American Medical Association.

King, Aubin Tilden ⊕ Major, U. S. Army, *retired, San Jose, Calif.*; University of Virginia Department of Medicine, Charlottesville, 1911; member of the American Psychiatric *Association; veteran* of World War I; entered the Medical Corps *of the U. S. Army* in 1920; retired Sept. 30, 1936, for disability in line of duty; died in the Letterman Army Hospital, San Francisco, July 11, aged 80, of thrombosis of the right middle cerebral artery, subdiaphragmatic abscess, cholecystitis, and bleeding duodenal ulcers.

Koerber, Kenneth Armin, *Philadelphia*; University of Pennsylvania School of Medicine, Philadelphia, 1930; member of the Medical Society of the State *of Pennsylvania; certified by the National Board of Medical Examiners; at one time medical director* of the Cramp Shipbuilding *Company; served on the staff of the* Germantown Dispensary and Hospital; *died in the Philadelphia* General Hospital July 24, aged 50, of agranulocytosis.

Krieger, George Madison ⊕ Michigan City, Ind.; Miami Medical College, Cincinnati, 1906; member of the American Academy of Ophthalmology and Otolaryngology; died in St. Anthony Hospital May 22, aged 74, of coronary sclerosis.

Langstadt, Arthur ⊕ Flushing, N. Y.; Ludwig-Maximilians-Universität Medizinische Fakultät, München, Bavaria, Germany, 1909; died in the New York City Hospital, New York City, July 20, aged 72, of myocardial infarction.

McClanahan, Zenas H. ⊕ Colorado Springs, Colo.; Colorado School of Medicine, Boulder, 1894; fellow of the American College of *Surgeons; past-president of the El Paso County Medical Society; on the staffs of the* Memorial Hospital, St. Francis Hospital, *and the* Glockner-Penrose Hospital, *where he died July 6, aged 85, of cerebral thrombosis.*

McGrew, John Merritt ⊕ Wellington, Kan.; University of Kansas School of Medicine, Kansas City, 1927; veteran of World War I; on the staff of St. Luke's Hospital; died in St. Francis Hospital, Wichita, July 25, aged 56, of chronic nephritis and uremia.

MacLean, Aubrey Bertram, New York City; McGill University Faculty of Medicine, Montreal, Quebec, Canada, 1919; died Aug. 1, aged 60, of carcinoma of the stomach.

Magaziner, William Edward, *Philadelphia*; Medico-Chirurgical College of Philadelphia, 1903; *an associate member of the American Medical Association; on the staffs of the* St. Luke's Hospital *and the* Lankenau Hospital, *where he died July 13, aged 73, of heart disease after an operation.*

Moffatt, Benjamin Harrison ⊕ Shelby, Ohio; Medical College of Virginia, Richmond, 1915; for many years city health commissioner; on the staff of the Shelby Hospital, where he died July 28, aged 67, of coronary occlusion.

Mogavero, Francesco ⊕ Philadelphia; born in Philadelphia Sept. 28, 1902; University of Pennsylvania School of Medicine, Philadelphia, 1925; certified by the National Board of Medical Examiners; specialist certified by the American Board of Surgery; member of the American Trudeau Society; fellow of the American College of Surgeons and the International College of Surgeons; on the staffs of the Doctors Hospital and the Misericordia Hospital, where he died July 22, aged 53, of cerebral hemorrhage.

Mostkowitz, Israel, Jamaica, N. Y.; Long Island College Hospital, Brooklyn, 1910; member of the Medical Society of the State of New York and the American College of Gastroenterology; on the staff of the Queens General Hospital; died July 31, aged 60, of subacute myelogenous leukemia.

Moyer, John Sanford, Metuchen, N. J.; University of Pittsburgh School of Medicine, Pittsburgh, 1921; certified by the National Board of Medical Examiners; specialist certified by the American Board of Otolaryngology; member of the Medical Society of the State of New York and the American Broncho-Esophagological Association; fellow of the American College of Surgeons; veteran of World War I; served on the staff of the Manhattan Eye, Ear and Throat Hospital in New York City; died in the Muhlenberg Hospital, Plainfield, July 10, aged 60.

Nagle, William Thomas, Southington, Conn.; Medico-Chirurgical College of Philadelphia, 1914; member of the Connecticut State Medical Society; veteran of World War I; on the staff of the Bradley Memorial Hospital; died July 17, aged 64, of carcinoma of the lower jaw.

Neesen, Victor, *Fort Lauderdale, Fla.*; Long Island College Hospital, Brooklyn, N. Y., 1894; *died June 10, aged 83, of arteriosclerotic heart disease.*

Nuckols, Ernest Benjamin ⊕ Cumberland, Va.; Medical College of Virginia, Richmond, 1908; a member of the staff of the Southside Community Hospital in Farmville; died July 11, aged 78, of cancer.

Olivier, Charles Kossuth, Lafayette, La.; Medical Department *of Tulane University* of Louisiana, New Orleans, 1910; an associate *member of the American Medical Association; served as director of the parish board of health; died July 10, aged 75, of coronary thrombosis.*

Pacelli, Joseph Francis ⊕ New York City; Hahnemann Medical College and Hospital of Philadelphia, 1932; died in the University Hospital July 7, aged 51, of ulcerative gangrene of the leg and mouth.

Peterson, Frank Joseph, New York City; Fordham University School of Medicine, New York City, 1919; member of the Medical Society of the State of New York; on the staffs of the Bronx Eye and Ear Infirmary and St. Elizabeth's Hospital; died Aug. 3, aged 60, of carcinoma of the right kidney.

Porter, John Thomas ⊕ Baytown, Texas; Chicago Medical School, Chicago, 1935; interned at the Illinois Central Hospital in Paducah, Ky.; served a residency at St. Louis Southwestern Hospital in Texarkana, Ark.; veteran of World War II; died in the Hermann Hospital, Houston, June 28, aged 48, of cirrhosis of the liver and diabetes mellitus.

Poust, George Alvin, *Hughesville, Pa.; Jefferson Medical College of Philadelphia, 1895; an associate member of the American Medical Association; veteran of World War I; associated with the Muncy Valley (Pa.) Hospital; died July 12, aged 87.*

Proctor, Feaster Le Grand, Forrest City, Ark.; University of Nashville (Tenn.) Medical Department, 1898; served in France during World War I; died in the Veterans Administration Hospital, Memphis, Tenn., July 11, aged 80, of myocardial infarction.

Pulese, Felix L., Southold, N. Y.; New York Homeopathic Medical College and Flower Hospital, New York City, 1928; member of the Medical Society of the State of New York; was with the U. S. Public Health Service and served as a lieutenant commander in the Coast Guard during World War II; attending physician at the Eastern Long Island Hospital in Greenport; on the staff of the Veterans Administration Hospital in Northport, N. Y., where he died July 18, aged 51, of arteriosclerotic heart disease.

Reid, Stewart Woods, West Hartford, Conn.; Yale University School of Medicine, New Haven, 1913; formerly member of the board of education of Hartford; died July 24, aged 70, of carcinoma of the lung.

Reynolds, Harry St. Clair ⊕ *Norwich, Conn.*; Yale University School of Medicine, New Haven, 1910; at one time on the faculty of his alma mater; served on the staffs of the Hartford (Conn.) Hospital and the Grace-New Haven (Conn.) Community Hospital; at one time on the staffs of the Institute of Living in Hartford and the Connecticut State Prison; died July 19, aged 75, of acute dilatation of the heart.

Richeson, Hugh Harding, Louisville, Ky.; University of Louisville School of Medicine, Louisville, 1914; an associate member of the American Medical Association; veteran of World War I; served on the staffs of Childrens Hospital and the Kentucky Baptist Hospital, where he died July 24, aged 69, of adenocarcinoma of the rectum.

FOREIGN LETTERS

FINLAND

Status of Immunization.—In *Nordisk medicin* for July 19, Dr. B. Landtman points out that in 1954 a law was enacted rendering BCG vaccination compulsory under certain conditions. For example it is compulsory for 19-year-old tuberculin-negative persons. At present 80% of Finnish children have had this vaccination and, of the 181 children admitted in recent years for tuberculous meningitis to the Children's Hospital in Helsinki, only 2 had been properly vaccinated with BCG vaccine. Virtually all children are vaccinated against whooping cough and diphtheria either at child welfare centers or privately, usually between the ages of 3 and 9 months, revaccination being undertaken when school age is reached. Tetanus is rare in Finland, and systematic vaccination against it has not been attempted.

Pyloric Stenosis.—Dr. A. Backman in the same issue reports a series of 34 patients with hypertrophic pyloric stenosis, of whom 28 were boys. The diagnosis in most cases was verified by roentgenograms. There were, however, four patients in whom the radiological findings were not quite typical but in whom the clinical evidence was strong enough in itself to warrant the diagnosis. Medical treatment was given to 21 patients (with one death) and 13 were operated on (with four deaths). The medical treatment consisted of giving 1 or 2 drops of methylscopolamine nitrate by mouth six to eight times daily. The surgical treatment consisted of the Fredet-Ramstedt operation. Medical treatment should be tried first, although it takes more time. The success of the surgical treatment depends to a large extent on skilled preoperative and postoperative treatment.

FRANCE

Electroencephalographic Findings in Paroxysmal Tachycardia.—R. Gerard and co-workers at the meeting on May 13 of the French Society of Cardiology stated that (1) in 13 of 25 patients with paroxysmal tachycardia the tracings between the paroxysms were normal; (2) in the other 12 the only evidence of abnormality was a definite but variable degree of hyperexcitability; and (3) some patients complained of pain in one or both temporal regions and had a lowered convulsive zone. No specific electroencephalographic evidence of epilepsy was found in these patients. Antispasmodics were given to those patients who were hyperexcitable or who had a lowered convulsive zone.

Levarterenol.—At the same meeting R. Legrand and co-workers showed that levarterenol induces bradycardia, anomalies of P waves, variations of the P-Q interval, and extrasystoles capable of causing supraventricular or ventricular tachycardia in healthy as well as diseased subjects. Levarterenol may induce coronary occlusion, even in patients who are in good health. The drug should, therefore, be given with caution. Its use is not recommended in the treatment of paroxysmal tachycardia, and it is contraindicated in patients with ventricular tachycardia or auriculoventricular dissociation.

Hydroelectrolytic Metabolism and Postoperative Reequilibration.—E. Delannoy and co-workers say that those patients who suffer significant losses or protracted loss of weight after operation raise difficult problems of maintenance of the hydroelectrolytic and nitrogen balance (*La semaine des hôpitaux de Paris,* volume 32, 1956). Neither clinically nor by measuring the electrolytes in the plasma is it possible to decide on the amount of therapeutic agents required. In complex cases an evaluation of the intake and output of fluids and of sodium, potassium, and nitrogen is essential. If no abnormal losses are observed, dextrose infusions should be given for the first three days and 50 mEq. of potassium chloride daily. Only after four or five days is saline solution necessary. In the event of abnormal losses, these should be exactly made up, but the urinary output of sodium may be disregarded in the first few days. If there is protracted loss of weight, a positive nitrogen balance must be established.

Radiographic Study of Poliomyelitis of the Spine.—A. Grossiord and co-workers (*La semaine des hôpitaux de Paris,* volume 32, 1956) state that, in patients with poliomyelitis of the spine, before scoliosis is reported, films should be taken in corrected decubitus position, especially in frontal projection on the spine placed in forced lateral flexion. Only such a technique, supplementing the clinical data, allows a measurement of the deformity, a valid comparison between the successive films, and a reliable prognosis.

Hypertension Due to Pheochromocytoma.—Laroche and Reboul (*La semaine des hôpitaux de Paris,* volume 32, 1956) say that pheochromocytoma may cause permanent hypertension without paroxysmal signs. The condition is generally serious, developing rapidly and accompanied by symptoms associated with hyperadrenalemia. Biological tests for hyperadrenalemia are not reliable. In doubtful cases one should attempt to detect the adrenal tumor by means of roentgenograms, including retropneumoperitoneum. Treatment of pheochromocytoma is surgical. Its prognosis has been improved by the use of levarterenol, but the ultimate prognosis should always be reserved, because hypertension may recur within a few months of the removal of the tumor.

Malignant Hypertension.—P. Milliez and co-workers (*La semaine des hôpitaux de Paris,* volume 32, 1956) say that the role of a disturbance in unilateral renal arterial circulation in initiating certain arterial hypertensions is indisputable. The possible ineffectiveness of nephrectomy is merely evidence that the angiopathy had escaped its preliminary cause when this became detectable. The presence of unilateral lumbar pains and hematuria in a hypertensive subject should encourage further careful examination. Nephrectomy, in the case of unilateral renal lesions, whatever their cause, should be performed. It may, however, in some ill-defined manner, cause circulatory disturbances in the healthy kidney, which results in an aggravation of the hypertension and renal insufficiency.

Hypertension Treated with Rauwolfia.—Senechal and co-workers (*La semaine des hôpitaux de Paris,* volume 32, 1956) observed a young woman who was treated from 1946 to the time of writing for severe arterial hypertension. Her blood pressure had risen to 250/190 mm. Hg, and the treatment used had proved ineffective. She had become pregnant twice, but both pregnancies ended in miscarriage. Starting in October, 1954, she was given Rauwolfia, and her blood pressure returned to almost normal values (140/100 mm. Hg). She again became pregnant and was delivered of a normal infant.

INDIA

Amebiasis.—Kasliwal and Bhatia (*Journal of the Indian Medical Association,* Aug. 16, 1956) report the results of needle biopsy of the liver in patients with chronic intestinal amebiasis. The patients were examined for evidence of any associated infection such as malaria that might affect the liver. Thirty patients with only amebic lesions were selected for liver biopsy. The main findings in their order of frequency were lymphoma, diffuse parenchymal liver cell damage, disorganization of hepatic cell plates, focal necrosis, and portal infiltration. These were consistent with the diagnosis of subacute hepatitis. The changes are caused by Endameba histolytica, not by the bacterial associates, and are probably reversible.

The items in these letters are contributed by regular correspondents in the various foreign countries.

Railway Accident Relief Car.—Medical relief for victims of accidents on Central Railway's broad-gauge line is now provided for by an accident relief car, a miniature hospital on wheels. Designed by the mechanical and medical departments of the Central Railway, the car is the first of its kind in India. It has an operating room and ward accommodations for 18 patients. The operating room equipment embodies the latest devices, used in battleships, to withstand vibration while the train is in motion. It has its own sterilizing equipment, a kitchen, hot and cold running water, and a refrigerator. Members of the railway's St. John Ambulance Brigade will accompany the car, in addition to the normal complement of medical and nursing staff. These members are all potential blood donors.

Tuberculosis Services.—To train a sufficient number of persons for tuberculosis services, the government proposes to subsidize the establishment of about 15 tuberculosis demonstration and training centers under the second Five Year plan. These centers will train tuberculosis workers of all categories and also demonstrate the latest techniques in the diagnosis and prevention of the disease. Three such centers at New Delhi, Trivandrum, and Patna were established under the first plan. Two more are being established at Madras and Nagpur with the assistance of the World Health Organization. The centers to be established under the second plan will consist of (1) an epidemiological section for mass x-ray screening and BCG vaccination, (2) a clinical section for diagnosis and treatment, (3) a bacteriological section, and (4) a domiciliary service under the direction of a public health nurse. A full-time director will supervise the working of all four sections and will be responsible for coordinating their work from the preventive viewpoint.

Typing Poliomyelitis Virus.—In an article in the *Indian Journal of Medical Sciences* (10:511 [July] 1956), C. S. Swaminathan has recorded the antigenic typing, by means of tissue cultures, of strains of poliomyelitis virus isolated in Bombay. The viruses were isolated from the stools of patients with clinical cases of poliomyelitis and their contacts by inoculation of rhesus monkeys. Throughout the investigation the hyperimmune antiserums against poliomyelitis virus types 1, 2, and 3 supplied by the United States National Foundation for Infantile Paralysis were used. Of the 57 strains, 54 belonged to type 1, 2 to type 2, and 1 to type 3. Of the two type-2 strains, one was isolated from a contact of a patient during a period between epidemics and the other from a patient during the epidemic period.

SWITZERLAND

Carcinogens in Foods.—R. Truhaut (*Oncologia* 9:84, 1956) states that, in view of the carcinogenic action of dulcin, a synthetic sweetener, a foreign substance, in order to be approved as a food additive, should be shown through prolonged experimentation to be devoid of harmful effects in general and in particular of carcinogenic effects. Standards of purity for foreign substances to be added to foods are most important, because the harmful effects of additives are often attributable to impurities. This is especially true of dyes.

Consumption of Cigarettes by Physicians.—O. Gsell sent a questionnaire concerning their smoking habits to physicians and received 4,105 responses (*Schweiz. med. Wchnschr.* 86:675, 1956). Sixty-one per cent of the physicians (23% of the female physicians) were habitual smokers; 38.5% (9% of the women) smoked more than 20 cigarettes per day; 60% of the male smokers and 99% of the female smokers smoked only cigarettes; 47% of the smokers inhaled; and 48% of the male smokers used filters. There was no difference in smoking habits of physicians living in cities and those living in the country.

Influence of Amphetamine on Hydroxycorticosteroids.—Recognizing that the injection of epinephrine appears to stimulate the secretory activity of the adrenal cortex, Muller and co-workers (*Schweiz. med. Wchnschr.* 86:688, 1956) studied the variations in serum 17-hydroxycorticosteroids under the influence of dextroamphetamine. Although devoid of the peripheral sympatheticomimetic action of the levoisomer, this derivative possesses, like epinephrine, properties stimulating to the central nervous system. In the eight hours that followed the taking of dextroamphetamine in relatively strong doses (15 to 25 mg.), there was an increase in the serum level of the 17-hydroxycorticosteroids. The existence of a spontaneous nyctohemeral variation of the 17-hydroxycorticosteroids of the blood indicates a relation to the hours of the day when the experiments were conducted. After the taking of amphetamine, the average elevations of the 17-hydroxycorticosteroids, in relation to the control values measured at the end of the morning, the afternoon, and in the evening, were 48, 41, and 92% respectively.

After the taking of amphetamine, the leukocytes and the eosinophils behaved in general as after the administration of corticotropin and cortisone, but there was no correlation between the degree of elevation of the steroid level and the variation of the differential leukocyte count. The mechanism by which amphetamine raises the steroid level is difficult to determine. The authors believe that the elevation of the steroid level observed after the administration of amphetamine, as well as the signs of adrenal hyperfunction noted in animals under the influence of epinephrine, is based on the suprahypophyseal action common to these two substances. The central action of the epinephrine, if it seems analogous to that of the amphetamine, is, however, less intense and much more fleeting. This could explain why the infusion of epinephrine has not raised the steroid level in man.

Limits of the Treponemal Immobilization Test.—The serologic reactions to lipid antigens being insufficient, numerous laboratories now use the treponemal immobilization test. J. Delacretaz (*Schweiz. med. Wchnschr.* 86:645, 1956) states that in syphilitic patients the treponemal immobilization test becomes positive at the end of the primary period or at the beginning of the secondary period (later than the classic serologic reactions). In the absence of treatment, it remains positive during the entire development of the disease without showing the same tendency as the classic reactions to spontaneous return to negative. In such treponematoses as yaws, bejel, and pinta, the treponemal immobilization test may be positive. In healthy subjects and in patients with nontreponemal diseases, the treponemal immobilization test is always negative. This is particularly important in checking biologically false reactions of the classic serologic tests. Like the classic serologic reactions, the treponemal immobilization test is more likely to become negative under the influence of the treatment according to how early in the disease the treatment is undertaken. As a general rule, the treponemal immobilization test becomes negative later than the classic serologic reactions under the influence of treatment, but this rule has certain exceptions. There is no assurance that the persistence of the immobilizing antibodies in the serum of a properly treated patient is incompatible with cure. A treponemal immobilization test remaining positive thus is not by itself an indication for continuing treatment. The author has not observed reversion to positive after the treponemal immobilization test has become negative. A negative treponemal immobilization test (repeated after three months in order to exclude all possibility of technical error) is thus presumptive evidence of cure. The author found the test to be indicated chiefly when positive classic serologic reactions were not accompanied by any sign of syphilis or when lesions suspected of being due to late syphilis were accompanied by negative classic serologic reactions.

Osmotic Nephroses.—Morard (*Helvet. med. acta* 23:215, 1956) reported a series of seven patients with nephropathies similar to the so-called osmotic nephrosis. These patients were given dextrose solution intravenously in amounts not exceeding the therapeutic norms or the tolerance to saccharides, but the preexistence of hyponatremia and the severe liver dysfunction seem to have potentiated, in each of these patients, the morphological expression of the osmotic imbalance. The author investigated the effects of giving dextrose solution in rabbits with electrolytic imbalance or hepatic insufficiency. One group of animals received a dextrose overloading of 15 gm. per kilogram of body weight intravenously; a second group received an overloading of 15 gm. per kilogram, together with a saline depletion by means of peritoneal dialysis, taking care not to modify the weight of the animals; and a third group received a purely hydric overloading aggravated by a loss of salt through peritoneal dialysis. Comparison of the histological changes indicated osmotic hepatonephrosis and that the saline depletion reinforced the osmotic action of the dextrose. Several factors may produce this morphological constancy, provided they disturb the electrolyte balance between the cell and its medium. An additional study was carried out in which the hepatotoxic effect of cinchophen was associated with dextrose overloading of 15 gm. per kilogram of body weight. The author found that the nephron reaction to the dextrose injection was not reinforced by the liver damage produced by cinchophen, but, for several reasons, this unsuccessful attempt does not negate the role of hepatic dysfunction in potentiating the osmotic nephrosis.

Ion Exchange.—By giving a salt-poor diet with the addition of sodium bicarbonate, P. Jeanneret (*Helvet. med. acta* 23:60, 1956) studied mineralocorticoid activity under conditions of normal sodium and low chloride intake and excretion. Under these circumstances, desoxycorticosterone acetate produces a marked retention of sodium and a significant loss of potassium, with no water retention. These observations, correlated with other studies where chloride was given without sodium, show that mineralocorticoid activity primarily affects tubular sodium reabsorption and that chloride retention is only a consequence of sodium retention. The potassium loss is interrelated with sodium retention, while the retention of chloride plays no part in this process. Water retention incidental to mineralocorticoid activity is not dependent solely on sodium retention; chloride also must be retained. Sodium retention alone does not lead to water retention. This last observation shows the need for reevaluation of the prevailing concept of the role attributed solely to sodium in water retention and points back to the classic view, that both sodium and chloride (salt) retention are necessary for formation of edema. With regard to dietetics, these results show that a sodium-poor diet prevents all direct steroid effects on electrolyte metabolism. This protecting effect, which is highly desirable when patients with normal adrenal cortex are treated with steroids having mineralocorticoid activity (cortisone, hydrocortisone, and fludrocortisone), is neutralized by sodium chloride and by other sodium salts. With sodium bicarbonate the potassium loss is much more pronounced than with sodium chloride. Alkalinizing sodium salts are therefore strictly contraindicated in these circumstances. When, on the other hand, a chloride such as ammonium chloride is given alone, the situation remains the same as with a salt-poor diet and no mineralocorticoid activity can be elicited.

Placental Extracts.—S. Rauch (*Helvet. med. acta* 23:75, 1956) in a study of human placental extracts concluded that the placenta is rich in enzymes, hormones, and mucopolysaccharides. These substances, however, are not contained in all the extracts. Their presence depends on the manner in which the extracts are prepared. The author considered four commercial preparations, three of which (extracts B, C, and D) were extracted according to Filatov's method, whereas the fourth extract (extract A) was prepared by the cold method. On the average, the most successful clinical results are obtained with extract A. The author made chemical and biological tests on these extracts in an attempt to find histochemical relations. In extract A, he found the following characteristics not found in the other extracts: (1) a high alkaline and acid phosphatase content; (2) an albumin fraction with amino acids, which can be electrophoretically demonstrated; (3) a high content of mucopolysaccharides and substances that migrate electrophoretically with beta-globulins; and (4) the strongest respiratory stimulating effect with a low-concentration optimum, i. e., with a 5% solution of the extract. This can be partly accounted for in terms of the ferment and hormone content, which, in the case of the other extracts, is lost as a result of the heating of the preparations. The component that stimulates breathing need not be identical with that which stimulates proliferation. Microimplantations, obtained by the same conservative method, were much less effective than the extract. The factors that exert the most stimulating effect on the tissues still remain unknown. They do not appear to form a part of the protein fraction, but rather of the water-soluble substrate. The stimulating effect on the breathing is largely confined to the mesenchymatous tissue; the epithelial tissue barely reacts at all. In view of these findings on the placental extracts, it is impossible as yet to give exact indications for their therapeutic use. The most favorable results are to be expected in the case of processes of the mesenchymatous tissues and, in that field, mainly on the strength of their influence on the intracellular ground substance.

UNITED KINGDOM

Tranquilizing Agents.—The Council of the Pharmaceutical Society of Great Britain is concerned about the situation produced by the recent introduction of a number of new products commonly known as "tranquilizers." Although they are not advertised to the public, a widespread public knowledge of them has been created by newspaper articles, and there is a substantial demand for them otherwise than on prescription. The indiscriminate use of such drugs is against the public interest, and pharmacists are urged not to display them or to supply them unless satisfied they will be taken on medical advice.

Mental Illness in Scotland.—Voluntary patients now represent practically 72% of the total admissions to mental hospitals in Scotland, according to the 1955 annual report of the General Board of Control for Scotland. Although, compared with the previous year, there was an increase of 657 in the number of admissions, these were exceeded by discharges and deaths, so that at the end of the year there were 57 fewer patients in mental hospitals than in 1954. All but one of the mental hospitals in Scotland were built more than 50 years ago. Television is often successful in stimulating the interest of chronic and apathetic patients. Several hospitals now supply attractive evening or party dresses for women patients to wear on special occasions such as dances, and two conveniently placed hospitals have arranged for parties of patients from one hospital to visit the other, alternating each month. These visits, during which football and billiard matches and other forms of entertainment are arranged, are greatly appreciated by the patients of both hospitals.

Two Americans Honored.—The Royal College of Surgeons has conferred the honorary fellowship of the college on Dr. I. S. Ravdin, of the University of Pennsylvania, who will visit London in December to deliver the Moynihan Lecture before the college. The Council of the Royal Institute of Public Health and Hygiene has appointed Prof. Philip Drinker, of Harvard University, as the Harben Lecturer for 1956. The subject of Professor Drinker's lectures, which will be delivered in May, 1957, is "Air Pollution and the Public Health."

Generalized Vaccinia.—Four cases of generalized vaccinia in one family were reported by a health officer in the East End of London. Two weeks after the youngest member of the family, aged one year, had been vaccinated, the 6-year-old sister was admitted to the hospital with a fever and rash of three days' duration and was found to have generalized vaccinia. Subsequently the father and two brothers were also admitted to the hospital because of accidental vaccinial infection of the face. All made uneventful recoveries. The mother, who was not affected, was vaccinated in infancy. The rest of the family had never been vaccinated.

Osteochondritis Dissecans in the Army.—Col. Charles M. Marsden and Capt. George Wiernik, R. A. M. C., have analyzed a series of roentgenograms of joints of 18,405 men that were made at the Cambridge Military Hospital, Cambridge, during an eight-year period. The ages of the men ranged from 18 to 30 years. There were 427 cases of osteochondritis dissecans. The diagnostic criterion was evidence ranging from definite localized subchondral decalcification to a chondral or osteochondral loose body or an osteochondral defect in the bone. The knee was the joint most commonly involved (299 cases), followed by the elbow (85 cases), the ankle (35 cases), and the hip (12 cases). The presenting symptom was pain, followed by swelling and instability. Locking episodes were common in the elbows and knees. In these joints arthrotomy for removal of the loose body relieved the locking, but the pain and instability tended to be unaffected. In the ankle, pain was greatly relieved by the removal of the loose body. In the hip, painful limitation of movement in all directions was the presenting symptom in each case. Treatment was palliative. If the lesion does not heal by recalcification or, in more advanced cases, by revascularization with maintenance of the normal contour of the affected bone, a mechanical osteoarthritis of the joint gradually develops.

Fluoridation of Water.—The annual report for 1955 of the Central Health Services Council to the Minister of Health, states that, in two areas in England, one in Wales and one in Scotland, arrangements are now under way for fluoridating the public water supplies at a rate of 1 ppm and for the examination of the teeth of the children in each area before, during, and at the completion of the studies, together with the dental examination of children in control areas. In view of the outcry in certain sections of the community against fluoridation of water supplies, the council devotes much space to the ethical issues involved. By accepting the recommendation that before any general introduction of fluoridation there should be study demonstrations in selected areas, the government has taken steps to insure full opportunity for well-informed opinion to develop.

Poliomyelitis and Housing.—Impressed by the lack of evidence supporting the popular belief that the severer forms of paralytic poliomyelitis tend to be commoner in superior environmental conditions, I. N. Sutherland (*Health Bulletin* 14:52, 1956) has studied the incidence of poliomyelitis in Scotland with respect to the number of rooms and the number of persons per household of victims. Superior households were those with relatively few persons living in a relatively large number of rooms. His figures fail to produce any evidence to support the contention that a superior household environment is associated with a higher incidence of paralytic or nonparalytic poliomyelitis. In the period 1950-1953, the rate per 100,000 population for paralytic poliomyelitis in one-room houses was 18.4 when there were three or less occupants and 69.4 when there were seven or more occupants. In houses containing five rooms or more, the comparable figures were 7.8 and 43.8 respectively. For the same period the rate for nonparalytic poliomyelitis was 5 in one-room houses with three or less occupants, 40 in those with seven or more occupants; 0.8 in houses with five or more rooms with three or less occupants, and 19.7 in those with seven or more occupants.

Psychological Factors in Pulmonary Tuberculosis.—The importance of psychological factors in pulmonary tuberculosis was investigated by D. M. Kissen (*Health Bulletin* 14:44, 1956) in 267 patients attending a diagnostic chest clinic for the first time. Subsequently, and unknown to Kissen until after he had comcompleted his investigation, 88 of these patients were given diagnoses of pulmonary tuberculosis. The remaining 179 patients were used as controls and subdivided as follows: 20 had some form of psychosomatic disease; 68 had no discoverable abnormality; and the remaining 91 patients had miscellaneous conditions. Antecedent emotional factors were found more frequently in the group with pulmonary tuberculosis than in the controls (65.4 and 26.2% respectively). This significantly higher incidence for tuberculosis still held true when compared with the subgroup with no abnormalities (23.5%) and the heterogeneous group (22%), but not when compared with the psychosomatic group (55%). The most common factor was a break or a serious threat of a break in an engagement or a marriage. Other factors were family bereavement or breaks in the family circle. However, the types of emotional factors in the psychosomatic group could not be described as broken love links. There was a significantly higher incidence of emotional factors in tuberculous patients over the age of 35.

This characteristic emotional factor suggested that these patients were especially in need of love or affection. It was therefore decided to investigate this point in a further 45 patients attending the chest clinic for the first time; 20 of these turned out to have tuberculosis, and the other 25 were treated as controls. All 20 tuberculous patients, but only four of the controls, were found to have this characteristic personality trait. Deprivation of natural parental affection was found in 12 (60%) of the tuberculous patients, compared with only four (16%) of the controls. This suggests that the combination of a break in the love link and an inordinate need for affection strongly predisposes to the development of pulmonary tuberculosis.

Sports Injuries.—Of all types of accident in the Royal Air Force, sports account for 28% (*Proceedings of the Royal Society of Medicine*). Because more than 90% of these are due to football, a group of football players will be given special exercises to strengthen their leg muscles. Their experiences will be compared with those of players not so trained. Athletics produce a surprising number of casualties, principally of the ankle ligaments and tendo calcaneus. Dr. W. D. Fletcher states that interference with the higher intellectual function can occur after one bout of boxing; 5% of those who remain in boxing five years become punch-drunk.

Naturopath Sentenced.—Brown Neil, a naturopath, was found guilty of trying to obtain $1,400 by false pretenses from an elderly woman and sentenced to two years' imprisonment. The prosecution said Neil had pretended that a Dr. Franz Schwartz, then living in the United States, had diagnosed Mrs. Swift's condition as cancer in the blood. Neil claimed he had power to treat and cure Mrs. Swift with the aid of equipment called the supersonic pulsator. Mrs. Swift received an unsolicited letter postmarked North Hollywood, Calif., and purportedly written by Dr. Schwartz's secretary. Among statements in the letter were that Dr. Schwartz was still busy supervising the treatment of President Eisenhower; that he had treated a member of the Royal family, who in addition to paying a fee of $2,800 had given a further $42,000 to help poor patients; that on Feb. 15 he had sent his assistant under hypnotic influence to Mrs. Swift's home; and that the assistant examined her sleeping body and found her to have a malignant neoplasm. The treatment was to be by broadcasting from the United States and England by wave-producing instruments. The letter ended by saying that the writer had asked Dr. Brown Neil, of Bournemouth, to treat Mrs. Swift under Dr. Schwartz's direction. In another letter received by Mrs. Swift at the same time signed "Dr. Johnson, M.D.," it was requested that payment for treatment be made by $1,400 in notes. These should be wrapped in brown paper and given to Dr. Neil. Mrs. Swift testified that she was in good health; that she had never heard of Dr. Schwartz; that she took the letters to her solicitor and, on police instructions, wrote to Neil for an appointment; and that she saw Neil on March 20. At her request, he took the brown paper parcel from her shopping bag but put it back when police officers entered. Neil told the police that he did not know Dr. Schwartz, but later he said: "If it will help you, I am Dr. Schwartz." After the trial Mr. A. Samuels, representing the British Naturopathic Association, Ltd., denied that Neil was a member of the association.

A Pathologist's Pay.—The following excerpt from a letter appears in the *British Medical Journal* of Aug. 4 and is quoted to show one aspect of the present-day relationship between medicine and other forms of livelihood. "I wished to become a pathologist when I qualified in 1952, but found that at no time in the ensuing seven or eight years was I likely to earn $2,800 per annum. I therefore entered the family business, where I pay a good representative over $2,800 per annum, plus car, plus expenses. Our travellers have no technical training and their only qualification is that they can sell our goods. It seems altogether wrong that if I were to offer them the salary of a doctor with higher qualifications . . . they would leave forthwith. Most young men qualifying in medicine desire to get married, have a home, a family, security, and freedom from debt. . . . What hope have they got of obtaining luxuries like a car, a television set, or a public school education for the children? I would have preferred to earn my living in my profession, but I wished to marry and felt that I owed my family a minimum standard of living. . . . Worse still, there was . . . little hope for the future, for even if I had higher qualifications what chance had I of obtaining a consultant's post?"

CORRESPONDENCE

WHIPLASH INJURIES

To the Editor:—I would like to comment on the paper by Gotten entitled "Whiplash Injuries" that appears in this issue on page 865, for which the clinical studies have been so well planned and executed. The author and his colleagues deserve a sincere compliment for having presented these facts concerning whiplash injuries, which are becoming so very common. It was three years ago that Dr. Gay and I presented before the Section on Nervous and Mental Diseases a small series of patients (50) with the whiplash injury syndrome. We had attempted to analyze this group and present certain clinical facts that characterized this traumatic syndrome and its subsequent course. Briefly, the syndrome of various aches, pains, and soreness was shown to be due to an acute injury to the cervical musculoligamentous structures and occasionally also due to injuries to the cervical neuroskeletal elements. Although the injury was incurred by several mechanisms, it was most frequently incurred when an auto was struck from behind and the occupant's head, acting as a semi-freely movable object, was suddenly hyperextended and subsequently less violently flexed (see figure). A second phase of this problem, which was strongly emphasized, was what might be termed the "iatrogenic phase." It was shown that the symptoms may be prolonged for weeks to years by ill-advised therapy, or lack of therapy, as handled by various types of medical regimens, physicians, osteopaths, and chiropractors. This, we felt, was an important aspect of the problem, from both the physical and the emotional or psychiatric approaches. Too often, the patient was conditioned for anxiety and tension. This state was developed either by the physician's lack of concern or through an overly anxious and solicitous attitude on his part. When the latter was evident, it suggested to the patient that a serious injury had occurred to his neck and that he would need extensive treatment. Usually this approach was followed by overtreatment, many times including what we believe is the ill-advised rigid fixation of head and neck.

We were able to show that some 70% of our patients displayed a psychoneurotic overlay. Most of these neurotic states or reactions were those of severe anxiety and tension. A further review of this original group, along with another series now comprising some 174 patients presently under study, has shown this to be true. In addition, we have seen reactive depressions appearing in some patients whose symptoms have continued to harass them for months or even years. We have recognized that a prolonged nervous tension state and a fear of (1) pain, (2) serious injury to the neck, and (3) paralysis tends to force the patient to hold his head rigid; in doing so, the patient ironically induces pain, soreness, and aching in the posterior cervical, suboccipital, and shoulder areas. Thus are perpetuated the common symptoms of a whiplash injury.

Before going on to the next point, I should note here that other symptoms of the whiplash injury syndrome may well be compared to the cerebral concussion state. In this syndrome, emotional disturbances are commonly known to perpetuate the symptoms (dizziness, giddiness, headaches, and syncopal-like states) that may be characteristic of the cerebral (cerebroscalp) vasomotor imbalance state. We believe that many of these patients with whiplash injuries have had mild cerebral concussions and that emotional factors play the same role here in perpetuating these symptoms.

Soon after our paper was read before the Section on Nervous and Mental Diseases, Dr. Von Hagen began to gently urge that we study the third phase (phase one being the patient's primary emotional reaction to the injury and subsequent symptoms; phase two, his reaction to his physician's attitude and therapy; and the third phase, the patient's reaction to the legal aspects of his injury. Was there such a reaction? If so, was it adverse in relation to his recovery? What happened to him after this (third) phase was removed?

As we had more experience with these patients and their legal problems, we came to recognize that litigation was, is, and always will be a serious factor in the course and therapy of these patients. At one time we attempted to ascertain how many of 110 patients with whiplash injuries had (1) employed legal aid, (2) litigation pending, and (3) litigation settled. This was done by a mailed questionnaire. The response proved to be most unsatisfactory, for only about a dozen answered this question, among some 15 questions asked, whereas all answered the questions about their symptoms! At the present time, we have under way (in its beginning) a program to have a young psychiatrist review some 225 cases. We hope to have, in another year, some data with which to answer many of these questions.

In the meantime, Dr. Gotten has brought to us irrefutable data concerning this third phase. He has accepted that there is such a syndrome as the whiplash injury syndrome and has shown the strong influence that litigation exerts on the ultimate clinical course of these patients. He has emphasized the monetary phase of this aspect and has not neglected the other aspects of this phase. I should like to draw attention to one facet of this "injury-litigation" problem that is seldom mentioned. Many patients have a fear of legal matters, particularly of "going to court." Of course, this is the fear of the unknown or unfamiliar. But this is just as real as the fear he also holds (1) that no punishment will be meted out to the driver of the other car (and these people do exhibit extreme hostility toward the driver of the other car) and (2) that no compensation will be received for the pain, anxiety, and loss of time that they have experienced. I have seen these patients, after the matter of litigation has been settled, relax and recover even though the legal decision was not in their favor. In these instances, the fear of the court procedure was as real and emotionally and physically decompensating to them as was the injury itself. I would suggest, therefore, that this aspect of the third phase be remembered.

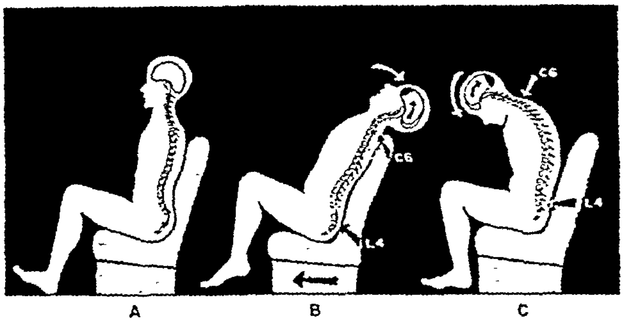


Diagram representing direction of head when vehicle is struck from behind and head is originally directed directly forward. Primary snap of head with greatest force is posteriorly (98% of 214 patients surveyed). Secondary movement is forward. Primary movement usually carries greatest force. However, if the vehicle hit is forced into an object in front at the right time, the secondary movement may be quite violent. It will be noted there is also force applied in the lower lumbar region. In several instances damage to intervertebral disks at the fourth lumbar level has occurred (three ruptured disks in this series).

Finally, it would seem that we have arrived at the same phase, or stage of progress, concerning whiplash-neck-injury syndromes, as we have with head injuries, particularly in regard to cerebral concussion. We accept that there are such injuries and that their symptoms are aggravated by hostility, anxiety, tension, and other emotional reactions. Finally, in both conditions, the ever-present element of litigation can and does affect the clinical course of these patients. In neither type of patient is it clinically possible to determine where the natural or physical course of the injury should end and where or when the perpetuation of the symptoms, due to the neurotic reaction, begins. Certainly one overlays the other in nearly all such cases, and it may be assumed that, in some, the emotional reaction begins with or immediately after the injury. It is, therefore, evident that we have made considerable progress in our understanding of this syndrome.

BUSINESS PRACTICE

LIFE INSURANCE FOR THE YOUNG PHYSICIAN

Robert H. Jordan
and
Harry E. Ungerleider, M.D., New York

The young physician today, with a background of schooling, internship, and fellowship in modern medicine, is better prepared to begin his practice than were physicians trained in earlier years. He lacks the dimension of experience, but he has intimate knowledge of the latest techniques that give new promise to all of medicine. The preparation by the young physician for his career has taken a longer period of time than did the training of earlier years; therefore, he is older when he graduates. The graduation of relatively large numbers of medical students who already have families of their own—with all the responsibilities of any other family men—is becoming commonplace. Frequently burdened with debt from training and setting up a practice, many of these young physicians defer establishing long-range family protection plans.

In view of this fact, it is not surprising that one of the earliest important problems that should be considered, namely, the establishment of a life insurance program, has never been discussed with many of them. They are not acquainted with the type of life insurance protection available to them and cannot spare the time to investigate so complicated a subject as life insurance. The informed underwriter is trained to assist his client by first diagnosing with questions and discussion the needs and objectives of the young doctor. Knowing these needs and objectives, he can prescribe the program fitted to the young doctor's requirements in their order of importance and, at the same time, can consult with him concerning the limitations necessary in order to keep the proposed purchase within the available budget. Furthermore, frequent review of these objectives and the policies is important to maintaining and building the ultimate program desired. Shopping for bargains or passing insurance business around on the basis of personal friendship will not contribute toward building a sound, integrated insurance program. Finally, there is no such thing as a correct plan for a certain age or income group; each plan should be tailored to the needs of the individual and the premium outlay he can afford. This article is written in the hope of furnishing certain information about policy forms and of stimulating consideration of how they are adaptable to the needs of the young physician when he is planning his program with a life underwriter.

Plans of Insurance

There are basically three types of life insurance policies: whole life, endowment, and term. Whole-life policies provide for the payment of the face amount of insurance only upon death. Premiums may be payable until death, as is the case under the ordinary-life plan; or they may be payable for some limited period, such as 20 years (or until death, if that occurs within 20 years), as is the case under a limited-payment-life policy. Premiums for limited-payment-life policies are higher than for ordinary-life policies because of the limited period for payment of premiums. Cash values under a limited-payment-life policy are also higher. Under either type of whole-life policy, the cash values increase during the life of the policy. A significant development in this type of insurance is that of the whole-life policy with premiums payable to age 60 or age 65, thus spreading the premium-paying period over those years of greatest anticipated professional activity and earnings.

Whole-life policies will normally be bought when the desire is to provide a reasonably large amount of insurance protection for the premiums paid while cash values accumulate. Cash values can provide protection against emergencies requiring ready cash or can be used at retirement to provide an income for life. The choice of a period during which premiums are to be payable must be made at the time the policy is issued and is often based on the individual's budget and his idea of when his earned income will cease. The ordinary-life plan is popular, since it provides the most whole-life-insurance protection for the lowest annual premiums. Twenty-payment-life and life-paid-up-at-65 plans are also popular.

Endowment policies, such as the 20-year-endowment policy, provide for the payment of the face amount on the endowment maturity date (the 20th policy anniversary for a 20-year endowment) or upon death, if earlier; premiums are usually payable during the whole of the endowment period (or until death). The premiums for endowment policies are higher than for corresponding limited-payment-life policies, since the face amount must certainly be paid by the end of the endowment period. Under the limited-payment-life policies, payment of the face amount is made upon death, which may occur considerably later than the end of the premium-payment period. Cash values available under endowment policies are higher than under corresponding limited-payment-life policies. The endowment plans are bought when the desire is to have a lump sum available on a predetermined date in the future should the insured survive until then. Many endowment policies are bought with a maturity date of age 65 for the purpose of taking an income settlement instead of a lump sum, that is, with the purpose of providing retirement income. Twenty-year endowments are also bought widely, many being purchased for the purpose of setting up an educational fund for a child upon maturity of the policy.

Term policies provide for payment of the face amount only upon death within the term period. Premiums are usually payable during the entire term period (or until death). The protection afforded by a term policy is temporary, with coverage existing only during the term period. Premiums for term policies are lower than for corresponding limited-payment-life policies, and, in most cases, there are no cash values available. Term insurance is usually purchased when the need is a temporary one and is for the largest amount of insurance that can be bought by the premium payable. Frequently the view that the need for insurance is temporary is supplanted by a later realization that permanent insurance is needed. Most term policies provide limited rights of conversion, without medical examination, to the regular permanent plans of insurance. Since these conversion rights are limited, the policy should be carefully studied so that the conversion rights may not be lost by a failure to elect conversion soon enough.

Almost all other plans of insurance can be classified as modifications or combinations of the three basic plans. Some of the more important plans to consider are those of special policies (generally issued only for large amounts) and renewable term policies. Many companies have in recent years introduced a special policy available only to the purchaser who is willing to buy insurance on this particular plan and for at least a minimum amount at which the special policy is issued. (This minimum may, for example, be $10,000.) Some companies offer these special policies only to specially selected or preferred risks. Recently the special policies have figured prominently as competitive items, inasmuch as the issuance of insurance in larger amounts has the effect of reducing the level of unit expenses; and, moreover, the cost of insurance may be further reduced when the policy is restricted to preferred risks. If the young physician has an insurance need that can be met by one of the special policies, he may be well advised to take advantage of the lower rates available under these plans. Some of these special policies offer the privilege of increasing the premiums at an age such as 55 for the purpose of making the policy paid-up or for its maturity as endowment at an age such as 65. Thus they become flexible and are readily adaptable to the larger income that may likely be available for premiums after the period when the normal need for the purchase of additional life insurance in substantial amounts has expired.

A renewable term policy can be best described as a regular term policy that contains an additional feature or benefit. This benefit is the right to renew the policy for another term period (usually without medical examination) at a premium rate guaranteed at the original issuance of the policy. The premium rate increases at each renewal, eventually becoming quite large as compared with the premium at the original age of issue, and

---

From the Bureau of Medical Research (Dr. Ungerleider), the Equitable Life Assurance Society of the United States.

ultimately at some age stated in the policy, usually in the middle 60's, it becomes necessary under these forms to discontinue the protection or convert it at the then attained age to the regular whole-life or endowment plans. The right to convert to the regular permanent plans is likewise usually available at the earlier ages, but too frequently in the experience of insurance companies it is not exercised when the higher premium can first be budgeted by the insured.

Important Features of Life Insurance Policies

In addition to the lump-sum death benefits that are available, life insurance policies contain many features that are of considerable value to the insured. One example of such a feature is contained in the beneficiary provision. This gives the insured the right to change his beneficiary at any time. It is also customary to allow the insured to name several persons rather than just one as his beneficiary and to provide that, instead of a lump sum, the death benefit will be held on deposit or will be paid under various installment options. The beneficiary provision provides the insured with certainty that the insurance benefits will be paid out in accordance with his wishes, since the terms of the beneficiary arrangement are carried out by the company as a matter of contract. The practice of private life insurance companies in carrying out such arrangements as a matter of contract contrasts with that under certain government plans, where benefits can terminate after the death of the insured upon occurrence of certain events, such as remarriage of the widow. Certain rights are also guaranteed the insured should he decide at some point after issue of the policy that he no longer wishes to continue making premium payments. The usual benefits available in such an event are a lump-sum payment of the cash value, continuation of protection for the full face amount of insurance for such period as the cash value will provide, or continuation of the policy as a fully paid-up policy for a reduced face amount of insurance providing the same form of benefits as would be available had premiums been continued.

There are many riders for "extra" benefits that may be included in a policy of life insurance. The two most popular provisions are for waiver of premiums in the event of total and permanent disability and for additional indemnity in the event of death by accidental means. The first provides that total and permanent disability, which results in reduction or discontinuance of earned income, will not cause termination of the life insurance policy. The second in its usual form provides for payment of double the face amount if death is caused by accidental means as defined in the provision. The cost of these benefits is small in respect to the premium for the basic policy, so that the majority of life insurance policies issued today contain at least one of these riders.

Family-income riders provide for the payment, commencing upon the death of the insured, of a monthly income until the end of a stated number of years from issue of the policy, with payment of the face amount of insurance at the end of that period. Such a rider might be added to the basic policy by a man recently become a father, with the thought that his family would be provided for by the income benefit until the child had grown up. There would then be a lump sum available that could be used for such purposes as providing a life income for the widow, setting up an educational fund, or helping to set the family up in business. Another purpose for which these riders are frequently used is mortgage redemption. The benefits available, which are of a reducing nature, can be made to correspond very closely to the reducing unpaid balance of a conventional mortgage. The family-income benefit can be purchased at a premium that is low compared to the premium for permanent plans of insurance. It should be remembered that the benefits available become less as the policy stays in force, so that the total benefit under the policy after the end of the family-income period is equal to the face amount. When setting up a program designed to guarantee the basic income needs for a young doctor's family, the use of the family-income rider on certain of the policies allocated to this need furnishes added protection when it is most essential and still leaves the primary policy intact for continuance as protection for the wife after the children are on their own, or even for retirement purposes, assuming the insured's survival to the older ages.

Disability-income riders provide for payment of monthly income usually until age 65 but frequently for life if the insured becomes disabled as defined in the rider. In most cases, the disability must occur before age 60. The amount of the monthly income is most often $10 per $1,000 face amount of insurance, so that a man having a $10,000 policy with this rider attached could collect an income of $100 per month should he become disabled. This benefit is of particular importance to physicians who become so disabled as to be unable to perform their usual duties. The cost of the rider is small in relation to the premium for the basic policy, but the benefits payable for disability occurring early in life are substantial. Frequently, however, the young doctor will consider a somewhat higher, although usually temporary, form of disability-income coverage offered by an accident and health policy instead of having this feature on policies incorporated in his regular life insurance program.

Premium Rates

It should be pointed out that insurance is sold on both a "participating" and a "nonparticipating" basis. Under a participating policy, the premium rate charged is somewhat higher than the premium considered necessary, with the anticipation that the excess premium will be returned in the form of dividends over the years. A nonparticipating policy provides insurance at a set premium rate, with no prospect of any dividend ever being paid. Under the participating policies, various attractive options are available for leaving the dividends with the company and for increasing the protection and cash equities in the policy. The figures shown in the table are illustrative of the premiums charged, the dividends paid currently, and the values contained in policies issued by a company that issues participating insurance. All figures are shown per $1,000 face amount, or, in the case of the family-income riders, per $10 monthly income. Dividends are not guaranteed but will depend on the actual experience over the years.

Let us see how a young physician, say age 30, with a wife and two children, one 2 years old and the other just born, might provide benefits for his family using life insurance. He wishes to provide his family with a maximum of protection while at the same time his policy is accumulating some cash values. This young physician might feel that a combination of one of the special policies for $20,000 with a 20-year-family-income rider would serve his purposes. This combination would provide income to his widow and children of $200 a month in the event aspirin and Demerol for relief of her distressing dyspnea. On this regimen she was able to return home. One month prior to the present admission she noted more rapidly increasing shortness of breath. Another physician noted distended neck veins, cardiomegaly, and pitting edema of the lower extremities. The dyspnea improved greatly with the use of mercurial diuretics and digitalis, although it still confined the patient to bed.

On admission to the District of Columbia General Hospital the patient complained of shortness of breath and pain in the right forearm and breast. Fluoroscopy revealed fair motion of the diaphragm. A mottled increase in density was seen throughout both lungs. This density tended toward confluence in the right lower lung field. Enlargement of the heart, mostly the left ventricle, was also seen. Seven blood cultures remained sterile. Sputum and gastric washings revealed no acid-fast bacilli. After an initial improvement resulting from diuresis, it became apparent that the patient was slowly losing ground. The slightest effort provoked extreme tachypnea. Fever persisted the first week in the hospital and reappeared with the onset of gastrointestinal bleeding. After a blood transfusion she admitted having a mild midepigastric pain intermittently over the preceding month. She described the pain as burning or gnawing and stated that it was sometimes relieved by food. She was placed on a modified ulcer regimen. Her death occurred 28 days after admission to the hospital. A review of the slides of lung tissue that had been obtained at biopsy in September, 1953, revealed changes typical of diffuse interstitial pulmonary fibrosis as described by Hamman and Rich.

This patient's illness was characterized by a slow, relentless loss of pulmonary function. The duration of symptoms was about 20 months. This is a longer duration of symptoms than that in the cases reported by Hamman and Rich. However, recent articles have also reported longer duration, and treatment with hydrocortisone may have prolonged the course of the disease. Cyanosis was not clinically evident, probably because it is difficult to evaluate clinically in the presence of anemia and particularly in Negroes. The gastrointestinal bleeding is interesting, since a duodenal ulcer was reported in other patients with this form of interstitial pulmonary fibrosis. The cause of diffuse interstitial pulmonary fibrosis as described by Hamman and Rich remains unknown. Several authors have speculated as to a virus etiology or some relation to the collagen diseases. That an altered state of tissue reactivity is present seems to be a reasonable assumption.

The Chemotherapy of Peripheral Tuberculous Lymphadenitis. O. H. Friedman and I. J. Selikoff. J. Mt. Sinai Hosp. 23:529-536 (July-Aug.) 1956 [New York].

Friedman and Selikoff present observations on 44 patients with peripheral tuberculous lymphadenitis who were treated during the past four years at the Mount Sinai Hospital in New York, N. Y. The generalized nature of tuberculous lymphadenitis must be appreciated, whether the local lesion is the result of a primary tuberculous infection or of a lymphohematogenous postprimary dissemination. Recent studies indicate that in the former case disseminated organ tuberculosis (pulmonary, meningeal, pleural, osseous) not infrequently follows the appearance of primary infection with local lymphadenitis. When peripheral tuberculous lymphadenitis is part of a postprimary lymphohematogenous dissemination, evidence of disseminated tuberculosis is often found in other organs. In view of this generalized nature, chemotherapy is necessary for every patient with active tuberculous peripheral lymphadenitis. Local therapy, such as excision, radiotherapy, and antimicrobial injections, may be useful as accessory treatment for the local lesion. Isoniazid alone or in combination with other antituberculous drugs is the treatment of choice. Data are still inadequate for the selection of an optimum regimen, but any chemotherapeutic regimen containing isoniazid will yield a high percentage of satisfactory results.

Chemotherapy must be prolonged; a minimum of one year is required. Short-term chemotherapy carries a risk of inadequate response and/or recurrence of disease. If there is a recurrence, it is usually in the same area as the original lesion. Response to chemotherapy is noted soon after its institution. Should no effect on the local lesions be noted in four months, the diagnosis of peripheral tuberculous lymphadenitis should be reviewed. Maximum response, however, requires a much longer period, and chemotherapy should be continued until it has been obtained and has remained stable for at least four months. Since peripheral tuberculous lymphadenitis is a chronic and relapsing disease, the patient must be kept under observation for a long time even after chemotherapy has been discontinued.

Treatment of Human Tuberculosis with Cycloserine. A. Ravina and M. Pestel. Presse méd. 64:1241-1245 (July 4) 1956 (In French) [Paris, France].

The authors report results of clinical experiments on 80 tuberculous patients treated with Cycloserine for 10 months. They recorded from 60 to 75% unquestionable improvement in subjects who were affected by chronic ulcerative cavitary processes and who were no longer responsive to other antibiotics. They also observed some rapid regressions in the cases of recent ulcerating, infiltrating processes. The daily dosage of Cycloserine was 2 capsules of 250 mg. initially, with gradual increase up to 5 capsules. The mechanism of action of the drug seems to differ from that of isoniazid and streptomycin. Cycloserine is slow to produce results at first but has a prolonged effect apt to continue for months. So far there is no clinical or experimental evidence of any eventual resistance of the bacillus to this medicament. A combination of Cycloserine and isoniazid proved remarkably effective in a large number of cases. It allowed the dosage of Cycloserine to be lowered and made it better tolerated. There were 12 instances of side-effects, chiefly of psychomotor type. Five of these were epileptic in nature. The authors emphasize the importance of a careful preliminary examination of the patients with a view to eliminating persons with psychotic symptoms and those with a history of epilepsy. They used encephalograms systematically after starting the treatment and in addition had the patients examined clinically to detect signs that would indicate that the treatment should be discontinued at least temporarily (irritability, change in humor, paradoxical asthenia, somnolence). Since Cycloserine is less manageable than isoniazid, its administration requires close supervision during the first weeks; consequently, its use should be carried out in medical establishments. Cycloserine is an additive antituberculous agent rather than a replacement for streptomycin, isoniazid, and *p*-aminosalicylic acid.

Drug Therapy (Mecamylamine) of Hypertension: III. Results with Mecamylamine, a Completely Absorbed Ganglionic Blocking Agent. J. H. Moyer, R. Ford, E. Dennis and others. A. M. A. Arch. Int. Med. 98:187-210 (Aug.) 1956 [Chicago].

Ganglionic blocking agents appear to be the most potent therapeutic agents for reducing the blood pressure in patients with severe hypertension. Recently another long-acting ganglionic blocking agent has become available for clinical trial. This compound, mecamylamine, is a secondary amine (rather than a quaternary compound) which is completely absorbed from the gastrointestinal tract. The authors describe observations on 104 patients from the hypertension clinics of several hospitals. The majority of these patients were treated entirely on an outpatient basis, but in a few patients with severe disease, such as hypertension associated with encephalopathy and cardiac failure, it was necessary to initiate therapy in the hospital. Twenty-four patients received mecamylamine alone, and 80 patients received mecamylamine and Rauwolfia together. The patients who received mecamylamine and Rauwolfia in combination responded more satisfactorily as a group when compared with the patients who received mecamylamine alone. Although mecamylamine appears to be an effective drug for reducing the blood pressure in patients with severe hypertension, certain problems arise in the management of these patients. It is particularly difficult to adjust the dose exactly so that the blood pressure remains stable throughout a 24-hour period. While some patients obtained an adequate response on a dose of 2.5 mg. of mecamylamine given twice a day, some patients required as much as 160 mg. per day. The use of an average dose is impossible and will lead to an intolerable incidence of complications. Some patients showed a very marked reduction in blood pressure in the upright position, with considerably less response in the supine position. The authors found it impossible to overcome this problem. Some patients displayed a marked early morning reactivity due to mecamylamine. In these patients it became necessary to reduce the night-time dose or, in many instances, discontinue it completely. Also, these patients required a relatively small breakfast dose.

The dosage of mecamylamine when given in combination with Rauwolfia is frequently less than when mecamylamine is used alone, and, as a consequence, there is less blockade of the parasympathetic nervous system. This reduces the severity of the side-effects resulting from blockade of this system, i. e., constipation, dry mouth, and blurred vision. Constipation is one of the most constant side-effects of mecamylamine therapy. If this problem is not combated vigorously, it may lead to fecal impaction and subsequently to ileus. If the constipation has progressed to ileus before adequate therapy is instituted, then the mecamylamine should be discontinued and 1 mg. of neostigmine should be given parenterally every hour until relief is obtained. If the condition is severe, standard methods for treating ileus should be employed. The possibility of aggravating a preexisting renal failure presents another problem. If the blood urea nitrogen level is above 80 to 100 mg. per 100 cc. of blood prior to therapy, reducing the blood pressure significantly usually aggravates the renal failure. If, however, the blood urea nitrogen level is only moderately elevated (40 to 60 mg. per 100 cc.), then judicious lowering of the blood pressure with a ganglionic blocking agent such as mecamylamine can be undertaken. In treating the patient who is considered a hypersensitive emergency, particularly if he is bedfast, it is usually better to administer reserpine parenterally as the initial procedure (rather than a ganglionic blocking agent).

The Role of Sulphonylurea Derivatives in the Management of Diabetes Mellitus: A Preliminary Report. E. Downie, J. Bornstein, B. Hudson and K. Taylor. M. J. Australia. 1:1072-1078 (June 30) 1956 [Sydney, Australia].

The mode of action of the sulfonylurea compounds upon the disturbed metabolic processes of diabetes mellitus is unknown. Although they seem to have the effect of lowering the level of blood sugar and of reducing the excretion of glucose by the kidneys in some patients, it cannot be assumed that these results are achieved by an action similar to that of insulin; in fact, they cannot be regarded as insulin substitutes. Janbon and his associates reported that *p*-amino-benzene-sulphonamido-isopropyl-thiadiazole reduced the blood sugar content of animals to hypoglycemic levels. Another sulfonamide derivative, 1-butyl-3-p-amino-benzene-sulfonylurea (BZ-55 or Carbutamide), and 1-butyl-3-p-toluene-sulfonylurea (Orinase) have also been shown to possess hypoglycemic activity. Carbutamide lowers the level of blood sugar, reduces glycosuria, and in some cases may replace insulin therapy. Success has been reported in clinical trials of the drug. It seems that the middle-aged obese patient responds satisfactorily to its use, but the young patient and the "brittle" one are uninfluenced, even by large doses. Experiments in animals have failed to show any serious side-effects from the administration of these drugs, even in high doses over long periods of time. In rare instances human patients have developed leukopenia, which has disappeared with a reduction in dosage of the drug. The failure of some patients whose plasma contains appreciable amounts of insulin to respond favorably to treatment with sulfonylurea compounds suggest that these drugs do not act by facilitating insulin action. It seems unlikely that they improve the condition of insulin-resistant patients who have demonstrable insulin in their plasma. At the present time there is potential danger in the indiscriminate use of these compounds, and further experience is necessary before their place in the treatment of diabetes mellitus can be determined.

Eosinophilic Leukemia. G. Cave Bondi and A. Lenzini. Sett. Med. 44:294-303 (June 15) 1956 (In Italian) [Florence, Italy].

The authors report the case of a 21-year-old patient with eosinophilic leukemic myelosis. The history of the patient showed no previous disease. The general condition of the patient was good when he underwent a medical checkup because of a feeling of heaviness in the left hypochondrium. A marked splenomegaly was found. All tests gave normal results except the hemocytometric test, which showed an increase of white corpuscles. Splenectomy was performed. The operation showed that there was no echinococcosis of the spleen. No improvement followed the operation. Two weeks after the intervention the white blood cell count reached 88,000. At the same time immature forms appeared in the circulation and the myelogram showed eosinophilic metaplasia in the bone marrow. Two months later the patient suffered a severe exacerbation of the leukemia with deep oropharyngeal ulcerations. Various therapeutic measures had little or no effect on the course of the disease. Ethylurethane given in doses of 3 gm. per day for three weeks had no effect. Cortisone and ACTH had no effect. A slight improvement followed treatment with Cloronaftina, a proprietary preparation of bis (2-chloroethyl) naphthamine.

The Incidence of Blood Group A in Pernicious Anemia. W. P. Creger and A. T. Sortor. A. M. A. Arch. Int. Med. 98:136-141 (Aug.) 1956 [Chicago].

Since the incidence of blood group A is significantly higher in patients with cancer of the stomach than in the general population, and since cancer of the stomach is three or four times as common in pernicious anemia as in the population at large, the incidence of blood group A in pernicious anemia seemed of some interest. Patient records that had been filed under the heading "pernicious anemia" at the Stanford University Hospitals (1937-1955), the University of California Hospital (1934-1955), and the San Francisco Hospital (1942-1954) were examined. Of 524 records that had been filed under the heading "pernicious anemia" at the three institutions, 115 contained a blood group determination and also satisfied the diagnostic criteria sufficiently to be regarded as representing cases of pernicious anemia. The blood group distribution of 20,070 donors provided control values. The percentage of persons who were group A was 35% higher in the cases of pernicious anemia than in the normal blood donors. The significance of the observed higher incidence of blood group A in pernicious anemia is shown not to be identical with that of the characteristic hair and eye color and ethnic origin of persons with this disorder. The increased incidence of blood group A in pernicious anemia as demonstrated in this report, and the previously reported increased incidence of the same blood group in gastric cancer, is interpreted as suggesting that both gastric cancer and pernicious anemia may be related to the occurrence of blood group A rather than being directly related to each other.

Paroxysmal Nocturnal Hemoglobinuria: Case Study, Including Evidence of Affection of the Marrow in the Disease. A. M. Nussey and D. W. Dawson. Blood 11:757-763 (Aug.) 1956 [New York].

A case of fatal paroxysmal nocturnal hemoglobinuria in a 65-year-old woman is described. The patient had bouts of abdominal pain coinciding with the frequent passage of dark urine. These bouts lasted for periods of up to two weeks at a time, with intervals of days or weeks between. Her condition was recognized when, after passing more than usually blood-stained urine, she looked very pale and showed a hemoglobin level of 5.2 gm. per 100 cc. The tip of the spleen could just be felt, but otherwise there was no noteworthy abnormality. Prolonged observation of the patient's urine confirmed the intensification of hemoglobinuria after a night's sleep and an unpredictable variation in its incidence from one week to another. The patient received cortisone for two and a half months, and this may have slowed down very slightly the drop in the patient's hemoglobin. The only treatment of proved value is blood transfusion, and the patient received 34 pt. of blood over a period of five years. If she went without transfusion for any length of time, her hemoglobin tended to find a level of about 5 gm. per 100 cc. and to stay at that point no matter how long the interval. This may mean either that the patient's marrow could keep production up to this level or that a proportion of her morphological blood elements were resistant to the hemolytic system.

Van den Bergh's finding that hemolysis in paroxysmal nocturnal hemoglobinuria is enhanced by increased acidity was confirmed, since all the morphological blood elements of the patient became lysed when suspended in acidified serum. There were no obvious incidents of thrombosis before the patient's final illness. A sudden onset of generalized headache and vomiting, drowsiness, and photophobia suggested the occurrence of venous cerebral thrombosis, but the recovery of xanthochromic cerebrospinal fluid on lumbar puncture was thought to favor the occurrence of a subarachnoid hemorrhage, and anticoagulants were therefore withheld. After a short-lived improvement the patient sank into a coma and died. Autopsy showed an extensive cerebral venous thrombosis and an old thrombotic lesion in the spleen and another in one adrenal. The mode of her death exemplified clearly the peril in which such patients stand from their thrombotic tendency. The abundance of iron in the patient's kidneys was in accordance with the general findings in paroxysmal nocturnal hemoglobinuria. The hemosiderosis in the liver, spleen, and an abdominal lymph node was probably caused in her case by the numerous transfusions she had received. The marrow of the sternum was hypocellular, and that of the ribs was aplastic. It seems reasonable to assume that in paroxysmal nocturnal hemoglobinuria the state of the marrow reflects not only the level of anemia but also the local activity of the hemolytic system, a hypercellular marrow showing a better capacity for coping with the disease than a less cellular marrow. The concept that the marrow in this disease is exposed to the action of the hemolytic system would explain why it does not rise to such regenerative heights as in congenital spherocytosis.

Newer Concepts of the Pathogenesis of Idiopathic Thrombocytopenic Purpura. C. V. Moore. Cincinnati J. Med. 37:295-299 (Aug.) 1956 [Cincinnati].

The results of studies carried out in patients with idiopathic thrombocytopenic purpura at the Washington University School of Medicine in St. Louis suggest that idiopathic thrombocytopenic purpura is a syndrome rather than a specific disease entity. In many patients, an immunologic mechanism seems to be of pathogenic importance, causing both accelerated destruction of platelets and damage to megakaryocytes. The thrombocytopenic, immunologic factor appears to be a platelet agglutinin. In 12 patients the antiplatelet factor was not demonstrated. It is suggested that in these patients a different mechanism was involved, and that inadequate production of platelets alone may be responsible for the thrombocytopenia.

The spleen apparently participates in the removal of sensitized platelets from the circulation, and probably produces some of the platelet agglutinin. This concept is supported by the following observations. After the injection of human plasma known to contain a high titer of platelet agglutinins, given to both a normal and a splenectomized recipient, the platelet level was lowered in both. However, when plasma with a low titer of platelet agglutinins was injected into two similar recipients, the platelets decreased only in the normal person; no lowering of the count occurred in the splenectomized patient. Splenectomy was performed on 20 patients with platelet agglutinins in their plasma. Fourteen responded to the operation, and six did not. Failure of splenectomy to correct the thrombocytopenia may be caused by the persistence of a high titer of platelet agglutinins after the operation. Another possibility that may be considered is that the spleen is of lesser importance in the production of thrombocytopenia in those patients who do not have platelet antibodies. Neonatal thrombocytopenia may develop from placental transmission of autoagglutinins or isoagglutinins.

Hageman Factor (HF) Deficiency. B. Ramot, K. Singer, P. Heller and H. J. Zimmerman. Blood 11:745-752 (Aug.) 1956 [New York].

Hageman factor deficiency was described for the first time in 1955 as a familial characteristic associated with deficiency of a clot-promoting fraction of plasma to which the name of the first patient in whom the newly discovered disorder was recognized was applied as an eponym. Hageman factor deficiency is a syndrome characterized by the complete absence of any hemorrhagic tendency in the presence of laboratory findings that, as a rule, are associated with severe disturbances in the hemostatic mechanism. The authors describe an additional case of this syndrome in a 60-year-old man of Lithuanian descent. He came to the United States at an early age and did not know anything about his parents or siblings. His two children and two grandchildren did not have any clotting abnormality. The patient was admitted to the Westside Veterans Administration Hospital in Chicago for the removal of large varicose veins. The results of all routine laboratory tests of his urine and blood were within normal limits except for a markedly prolonged clotting time of more than 60 minutes. The plasma prothrombin time was normal, but prothrombin consumption was decreased. The thromboplastin generation test according to Biggs and Douglas' technique revealed that Hageman factor is essential for blood thromboplastin formation at least in vitro. This test and additional studies made it possible to differentiate the patient's Hageman factor deficiency from similar "hemophilic syndromes" caused by lack of antihemophilic factor (AHF), or plasma thromboplastin component (PTC) or plasma thromboplastin antecedent (PTA). Transfusions of 50 cc. of 20-day-old blood rapidly restored the patient's clotting and serum prothrombin times to normal; the thromboplastin generation also became rapidly normal. This corrective effect was maintained for about 36 hours. Extremely minute amounts of Hageman factor seem to be necessary to normalize thromboplastin formation. The lack of spontaneous bleeding in fully developed Hageman factor deficiency and in plasma-thromboplastin-antecedent deficiency also suggests that these two factors are not essential in the maintenance of the physiological "integrity" of the vascular wall. Since any transfusion carries some risk, it is of practical importance to emphasize the fact that preoperative preparation with transfusions can be omitted in patients with Hageman factor deficiency.

Systemic Lupus Erythematosus: Recent Advances in Its Diagnosis and Treatment. E. L. Dubois. Ann. Int. Med. 45:163-184 (Aug.) 1956 [Lancaster, Pa.].

One hundred forty-five female and 18 male patients between the ages of 1 and 69 years with systemic lupus erythematosus were treated at the Los Angeles County General Hospital between 1948 and 1955. The apparently increasing incidence of this disease during the six-year period is a result of the more frequent use of the lupus erythematosus (L.E.) cell test and of a more inclusive concept of systemic lupus erythematosus, which is a chronic disease resembling rheumatoid arthritis. Part of the rising incidence may also be due to the perfecting of more sensitive techniques of L.E. cell detection.

Simultaneous L.E. cell studies were performed on 44 patients with systemic lupus erythematosus by four different methods, the use of two concentrations of heparin as an anticoagulant, a clotted method, and the recent Snapper ring technique. In 10 patients the clotted method was the only test that yielded positive results; in 4 patients the ring technique was the only one that gave positive results, and in two patients the heparinized specimen was the only positive one. With increasing amounts of heparin fewer L.E. cells were found. It is advisable that at least three different types of L.E. cell tests be performed to screen a suspected case adequately. Despite these refinements, L.E. cells may not be found in all patients with systemic lupus erythematosus.

The study of the histories of the 163 patients gave the best concept of the course of the illness. Sixty-three patients (38.7%) had spontaneous remissions before any special therapy was instituted. Ten patients (6.1%) had at least two remissions, and 26 (16%) had multiple remissions. This makes evaluation of therapy difficult, especially as none of the therapeutic agents used is specific and some may be hazardous. Bed rest alone is helpful in controlling symptoms in the active stages of the disease, but if a remission does not ensue after several weeks of rest more vigorous therapy should be instituted. If salicylates and rest fail, or if cutaneous lesions are present, then antimalarial drugs should be given. Quinacrine (Atabrine) hydrochloride, chloroquine phosphate, or amodiaquin hydrochloride were given to 134 patients with milder cases of the disease. The effect of these drugs on the cutaneous lesions was almost specific. The arthritis was also greatly benefited. Eighty per cent of the patients were benefited by antimalarial agents alone. One hundred seven (90%) of 132 acutely ill patients who were given a first course of steroid therapy were benefited. Daily doses of 300 mg. of cortisone, 240 mg. of Hydrocortone, or 40 mg. of prednisone or prednisolone were usually given before the illness was brought under control.

Steroid therapy is still the mainstay of treatment in the acutely ill patient, but its synergistic use with antimalarial drugs may often reduce the steroid dose and may occasionally permit discontinuation of steroid therapy. Nitrogen mustards were given to 33 patients who received 48 courses of methyl-bis (beta-chloroethyl) amine hydrochloride by intravenous route and 11 courses of triethylene melamine orally. The latter drug was discarded because of its toxicity. The most pronounced effects of nitrogen mustard therapy occurred in the edematous nephrotic patients with systemic lupus erythematosus in whom a marked diuresis developed within from a few days to two weeks after receiving the drug. Patients with active systemic lupus erythematosus without renal damage were not benefited by this treatment. These methods of treatment prolonged the lives of the patients. The median duration of life of 59 untreated or inadequately treated patients with systemic lupus erythematosus was 24 months. Only 33 of the 138 adequately treated patients with a duration of 24 months or longer of their disease, i. e., less than 10%, have died; this difference is significant.

Survival in Untreated and Treated Cancer. M. B. Shimkin, M. H. Griswold and S. J. Cutler. Ann. Int. Med. 45:255-267 (Aug.) 1956 [Lancaster, Pa.].

The cancer record register of the State of Connecticut, which has been in operation since 1935, most closely answers the requirements for a source of data from which estimates of survival with cancer among the general population can be derived. Between 1935 and 1951, 75,494 cases of cancer were diagnosed among the inhabitants of Connecticut, of whom there were two million in 1950. The five-year survival of male patients increased gradually from 12% between 1935 and 1940 to 20% between 1947 and 1951. For female patients the comparable increase was from 19% to 32%. This improvement in the survival rate did not result from earlier diagnosis of the cases, since there was no consistent or significant change in the distribution of localized and disseminated cases during the entire period of study. The improvement in the survival rate of patients with cancer occurred in those in whom the diagnosis was made when the cancer was clinically localized and when it involved regional areas, but not when it was disseminated. The most marked improvement in the survival rate has been recorded for cancer of the colon and rectum in patients of both sexes and of the uterine cervix in women. These data were compared with those of anticipated survival in patients with untreated neoplastic disease. The improvement in the survival rate seems to be the result of increasingly better treatment of an increasingly greater proportion of the patients. A new era of detection and treatment of cancer is being entered upon as a result of studies on in situ and occult cancers among the general population.

Salt-Losing Nephritis: Review and Report of a Case. A. H. Levere and L. G. Wesson Jr. New England J. Med. 255:373-376 (Aug. 23) 1956 [Boston].

The history of salt-losing nephritis is briefly presented and an additional case is described. The patient was a 29-year-old man who complained of weakness, nausea, and vomiting. Five weeks before his admission he began to experience aching and cramps in his limbs, accompanied or soon followed by nausea and vomiting without hematemesis and usually while he was riding in vehicles. He also noticed weakness, fatigue, exertional dyspnea, increasing thirst and polyuria, and a loss of 2.3 kg. (5 lb.) in weight. His condition deteriorated rapidly, although therapy for chronic renal disease was instituted. An electrocardiogram revealed prominent peaked T waves. The plasma potassium level at this time was 7.6 mEq. per liter. He became lethargic, had marked nausea, and vomited. He appeared better after an infusion of isotonic sodium chloride solution given in an attempt to correct suspected dehydration. Because of this, and the evidence of increased urinary excretion of sodium concomitant with a high degree of renal insufficiency, it was suspected that he had a salt-losing type of renal dysfunction. After he was treated for this condition he improved, and he was discharged after 68 days in the hospital.

After discharge he adhered to a low-protein diet with from 6 to 10 gm. of supplementary salt and 3 gm. of calcium lactate daily, returning regularly to the outpatient clinic for follow-up examination. Except for occasional calf and thigh cramps, he is relatively asymptomatic. Two needle biopsies were performed on the right kidney: the first revealed infiltration of the interstitial tissue by chronic inflammatory cells. The tubules showed extensive degeneration. Some of the six glomeruli observed showed irregular thickening of the basement membranes of the tufts and more marked thickening of the basement membrane of Bowman's capsule. The second biopsy revealed changes similar to those noted in the first specimen. Thickening of the basement membranes was present, supporting glomerulonephritis as the most probable pathological diagnosis. The degree of membrane thickening, however, is too mild to permit this diagnosis to be established beyond doubt.

Hyponatremia in the presence of a urine rich in sodium chloride is recognized also in Addison's disease. Salt-losing nephritis has many features in common with Addison's disease. It differs principally in that the defect in tubular sodium chloride reabsorption is organic, a consequence of renal disease, and hence irreversible by steroid administration. Hyponatremia with excessive renal salt loss has been recognized in certain patients with pneumonia, congestive heart failure, peritonitis, tuberculous meningitis, and particularly pulmonary tuberculosis. The inability of the kidneys to conserve salt efficiently is usual in chronic renal disease, although the loss of amounts sufficient to cause symptoms that dominate the clinical picture and simulate adrenocortical insufficiency is rare. It is not unusual, however, to observe that patients with chronic nephritis who have been placed on a low-salt diet to control edema formation may become somewhat dehydrated and then show a striking improvement when 1 to 5 gm. of salt is restored to the diet. It is likely, nevertheless, that salt-losing nephritis is a particular variant of chronic Bright's disease that differs from the more usual forms in more respects than a simple quantitative increase in the amount of salt lost in the urine. Therefore, the authors propose certain minimum criteria that should be met for the diagnosis of salt-losing nephritis as distinct from other salt-losing states: signs and symptoms consistent with dehydration are present on a normal salt intake (5 to 8 gm. per day) and can be relieved by an intake of 10 to 20 gm. of salt per day; the clinical state cannot be relieved by desoxycorticosterone acetate or, alternatively, steroids are present in the urine in normal amounts; and evidence of renal disease is present (low specific gravity, polyuria, elevated plasma urea and creatinine and anemia) and persists on high-salt intake. The salient clinical, laboratory, and pathological findings in cases reported in the literature are reviewed according to the proposed criteria. The authors are of the opinion that salt-losing nephritis is probably a variant of chronic glomerulonephritis or pyelonephritis in which deterioration of tubular function for the reabsorption of sodium chloride has proceeded more rapidly than deterioration of glomerular function. The prostration of the patients and its relief by salt are so dramatic, however, that the term deserves retention as designating a separate clinical entity.

Necrotizing Renal Papillitis: Twenty Cases from Medical Department: Is Incidence of the Disease Increasing? G. T. Pedersen and M. Schwartz. Ugesk. læger 118:829-834 (July 19) 1956 (In Danish) [Copenhagen, Denmark].

In 1953 one case of necrotizing renal papillitis was seen in medical department B of Bispebjerg Hospital; in 1954 there were seven cases; in 1955, 12 cases. The disease had not been encountered the two preceding years. In all but one case the diagnosis was verified at autopsy. The clinical picture did not differ from that observed earlier but was unilateral and marked by progressive uremia. Only three of the patients had diabetes. The causes of the increase are not known.

Necrotizing Renal Papillitis with Partial Reduction of Renal Function. F. Quaade. Ugesk. læger 118:845-846 (July 19) 1956 (In Danish) [Copenhagen, Denmark].

A man aged 43 with post-traumatic stricture of the urethra and history of recurrent urinary infection for 13 years developed marked thirst and polyuria. Diabetes insipidus and psychogenic polydipsia were excluded. Necrotic papillae were excreted the urine. Pyelography with sodium acetizoate diagnosis of necrotizing renal papillitis. E renal function showed a discrepancy between almost normal glomerular filtration and severely damaged tubular resorption. The case is regarded as an extreme example of the type of renal impairment met with in other conditions in which the pathological lesion wholly or mainly involves the distal part of the nephron.

Necrotizing Renal Papillitis: Case Followed More Than Six Years with Histological Verification by Voided Papillae. G. T. Pedersen. Ugesk. læger 118:846-847 (July 19) 1956 (In Danish) [Copenhagen, Denmark].

The author reports a case of papillary necrosis in a woman aged 53 who did not have diabetes mellitus and who at the start of the disease did not present signs of obstruction in the urinary tract. During six years' observation renal papillae were voided regularly. Treatment has been purely symptomatic and the patient has remained able to work in spite of gradually reduced renal function.

SURGERY

Surgical Treatment of Children with Coarctation of the Aorta. A. L. d'Abreu and C. Parsons. Brit. M. J. 2:390-393 (Aug. 18) 1956 [London, England].

During a period of five years at the Children's Hospital, Birmingham, 30 infants died from coarctation of the aorta within six months of birth. During the rest of the first decade a child with coarctation appears to be comparatively safe, but the hazard to life increases again at puberty, and the chances of reaching the age of 40 are poor. Operation has proved easier and safer in children than in adult subjects, and has usually been followed by a fall of blood pressure that has been progressive for a period of several weeks. Stricture formation may follow operative treatment. Subclavian aortic anastomosis, which should be regarded only as a substitute for the better end-to-end anastomosis, had to be used in two patients in whom this occurred. In the first case, after a long and difficult dissection and end-to-end anastomosis, the lower aortic segment developed a linear tear an inch in length. This was repaired, but further severe bleeding from the anastomosis required a rapid suture of both ends. The boy's condition became critical, and the operation was abandoned. Three weeks after this disaster his blood pressure was 240/170 mm. Hg and he complained of intractable headache; the chest was reopened and a large subclavian artery was divided, turned down, and anastomosed end-to-end to the lower aortic segment. Recovery was rapid, and five years later he was well, with a normal blood pressure. In the second case the stenosed area reached so high up to the arch that only an aortic graft or a subclavian aortic anastomosis would have been possible. Grafts were not available at that time, and the subclavian artery was therefore used; the result has been perfect.

Coarctation of the Aorta. W. P. Cleland, T. B. Counhan, J. F. Goodwin, R. E. Steiner. Brit. M. J. 2:379-390 (Aug. 18) 1956 [London, England].

The authors surveyed 52 patients (34 males, 18 females) with coarctation of the aorta treated by them. The patients' ages ranged from one to 55 years. Forty patients, no fewer than 25 of whom were 15 years of age or older, had resections. Of the 12 patients who did not undergo surgical treatment, 6 were over 40 when last seen, but 3 of these have since died, the oldest at the age of 55. Only nine patients presented themselves with symptoms referable to the coarctation; in all the other patients coarctation was found during examinations carried out for other reasons. In all 40 patients subjected to operation the aim was to perform an end-to-end anastomosis to achieve a full aortic lumen at the site of the union. In all cases the coarctation was of the "adult" type. The immediate postoperative course was uneventful in most cases. One patient died six hours after operation from rupture of a suture. Postoperative hemorrhage of severe degree occurred in two cases, but it stopped spontaneously after transfusion. The operation was fatal in three cases. The results have been satisfactory. The brachial blood pressure was lowered toward normal. Postoperative cerebrovascular accidents, bacterial infection, aortic aneurysm, and heart failure neither occurred nor recurred.

The pros and cons of operation may be summarized as follows— In favor: (1) the improbability of surviving past middle age; (2) the insidious or sudden nature of serious or fatal complications, such as aneurysm, endoaortitis, and cerebrovascular accident; (3) the reduction of blood pressure after operation; and (4) the low operative mortality. Against: (1) the difficulty of judging the risks to life in any individual patient; (2) the uncertainty that resection will prevent the onset of serious complications; and (3) the reluctance to subject a symptomless individual to a major operation of a prophylactic nature. Serious consideration of this difficult problem has led the authors to believe that the pros outweigh the cons. Consequently they recommend resection in all patients under the age of 40 unless it is contraindicated by the presence of severe associated cardiovascular anomalies unlikely to be affected by the resection. The ideal time for operation is before adolescence, because then the vessels are healthier and local vascular complications are less common. In addition, the likelihood of obtaining normal postoperative blood pressures is probably greater in the younger individual. Thoracotomy is tolerated better by the young, and anxiety states are unusual at this age. A relatively serious operation of election should be carried out before the individual has acquired responsibilities and dependents.

Carcinoma of Esophagus: Thirty-Three Cases. J. Costas Durieux. Bol. Asoc. méd. Puerto Rico 48:207-212 (May) 1956 (In Spanish) [Santurce, Puerto Rico].

Thirty-three hospitalized patients of both sexes with cancer of the esophagus are reported on. Most of the patients were between the ages of 50 and 70 years. The predominant symptoms were acute dysphagia and rapidly progressive loss of weight. In the majority of the cases the cancer was located in the middle fourth of the esophagus. The diagnosis was made radiologically and by esophagoscopy. Eleven patients were in an inoperable stage because of old age and cachexia. Of the 22 patients who were in an operable stage, only 11 were able to undergo resection. The lesion was located in the upper fourth of the esophagus in one patient, in the lower fourth in six, and in the middle fourth in four cases. Restoration of continuity of the alimentary tract was accomplished by esophagogastrostomy or by the use of a plastic tube. In the group of 11 patients who underwent resection there were four postoperative deaths, due to the following complications: coronary thrombosis, cerebral hemorrhage, renal insufficiency, and adrenocortical insufficiency. Rupture of the anastomosis occurred in no case. Two patients had a complicating fistula that healed spontaneously. One of these patients had a plastic tube for restoration of continuity of the alimentary tract. The author concludes that resection of the segment of esophageal cancer and restoration of continuity of the alimentary tract, either by esophagogastrostomy or with the utilization of a plastic tube, give satisfactory results in cases of resectable cancer of the esophagus. Resectability of cancer of the esophagus is inversely proportional to the height of the segment in which the lesion is located.

Early Clinical Results of Extended Radical Operation for Carcinoma of the Breast: Report on 100 Cases. W. Lentz. Beitr. klin. Chir. 193:64-68 (No. 1) 1956 (In German) [Munich, Germany].

A report is presented on the first 100 patients with carcinoma of the breast who underwent extended radical operation at the surgical clinic of the University of Kiel. The term "extended radical operation" is proposed for the operation, which combines Halstedt's classic radical operation with the resection of the internal mammary lymph node chain (parasternal lymph node chain). In the first operations the second or third costal cartilage was removed only occasionally, while in the operations that were performed later, the second and the third, or the second, third, and fourth costal cartilages were removed, always close to the sternum, about 1.5 to 2 cm. lateral to it, so that the mammary vessels with the lymphatic chain and surrounding adipose tissue could be clearly seen and removed. The operation was performed with the patient under intratracheal anesthesia. Thus it was possible to avoid a postoperative pneumothorax when the pleura was incised, as happened in 17 patients. Although a postoperative pleural effusion was observed in 10 of the 17 patients, and in an additional 9 patients, the pleural cavity did not become infected in any of them. In contrast to the plain radical operation, another typical complication of the extended radical operation consisted of secondary healing of the operative wound in 25 patients, in most of whom an accumulation of fluid had occurred in the area of resection of the costal cartilages. Four of the 100 patients died on the 6th, 15th, 21st, and 35th postoperative days respectively. These four patients were between the ages of 68 and 75; death resulted from embolism in two, from cardiac decompensation in one; and from a tension pneumothorax in one. The death of the last patient was most likely the result of the extended operation. The increased incidence of complications should be kept in mind when a decision must be made concerning the performance of an extended radical operation in a poor-risk patient.

Carcinoma of the Breast Metastasizing in the Mammary Lymph Node Chain: Report on 100 Cases. R. Graf. Beitr. klin. Chir. 193:90-97 (No. 1) 1956 (In German) [Munich, Germany].

Forty-one of the first 100 patients with carcinoma of the mammary gland who underwent extended radical operation at the surgical clinic of the University of Kiel, Germany, were in stage 1 and 59 were in stage 2 according to Steinthal's classification. Patients in stage 3 were not subjected to this type of operation. Parasternal metastases were observed in 5 (12%) of the 41 patients, and in 25 (42%) of the 59 patients. Twenty of the 41 stage 1 tumors were medial or central and 21 were lateral; metastases in the intermammary lymph node chain had developed from 4 of the 20 medial tumors and from only one of the 21 lateral tumors. Twenty-two of 59 stage 2 tumors were medial or central and 37 were lateral; metastases in the intermammary lymph node chain had developed from 13 of the 22 tumors, and from 12 of the 37 tumors. Frequently the metastases in the intermammary lymph node chain could not be recognized on macroscopic examination. It was only on microscopic examination that the following observations were made: Two small cancer nests were found in the marginal sinus of a parasternal lymph node. Cancer cell emboli in smaller or larger amounts frequently caused complete obstruction of the lymph vessels. When this happened, the carcinoma perforated the lymph vessel wall and continued its infiltrating growth in the parasternal adipose tissue. Finally the carcinoma also invaded the intercostal muscles, and occasionally the pleura. These observations show that clean removal of the entire parasternal tissue similar to that of the axillary tissue is required.

Infusion of 10 cc. of India ink into the sternal marrow of 30 cadavers and injections of 2 cc. of Trypan blue into the sternum of two dying patients revealed several lymphatic connections between the left and the right mammary glands. Such connections were observed between the superficial lymphatic network of the left and the right mammary glands in the areas of the cutis and the subcutis, and in addition between the right and the left intermammary lymph node chains retrosternally at the level of the second intercostal space, behind the manubrium in the area of the anterior mediastinum, and also intrasternally through the marrow cavity of the sternum.

Erythromycin Treatment of Staphylococcus Enteritis. E. H. Thaysen, K. H. Eriksen, H. E. Knutsen and F. Neukirch. Ugesk. læger 118:741-746 (June 28) 1956 (In Danish) [Copenhagen, Denmark].

In five out of six grave or moderately grave cases of micrococcic (staphylococcic) enteritis in which the tetracyclines were discontinued and erythromycin treatment instituted, rapid improvement resulted; one patient died, possibly because of too late start of the erythromycin treatment. Six additional cases of micrococcic enteritis not previously published are cited; the three in which the tetracyclines were not discontinued in spite of marked symptoms of micrococcic enteritis were fatal, and two of the three in which the tetracyclines were discontinued shortly before or on the appearance of the enteritis were fatal. The favorable experiences with erythromycin should not lead to its application in every case of diarrhea that may occur during treatment with tetracyclines, as the diarrhea usually ends on discontinuation of the tetracyclines. Grave toxic micrococcic enteritis is a rare complication. Too liberal use of erythromycin may increase the danger of development of resistant Micrococcus strains. Two factors are important in the prognosis in grave micrococcic enteritis: (1) immediate discontinuation of the tetracyclines and (2) oral administration of erythromycin if the diarrhea has not abated essentially during the first 24 hours. If the patient is seriously affected, this time interval may have to be shortened. Micrococcic enteritis is thought to be mainly nosocomial; one of the cases treated with erythromycin originated during Aureomycin treatment in the home and shows the possible risk in ambulant Aureomycin treatment of patients recently discharged from hospital.

Two Fatal Cases of Staphylococcus Enteritis After Antibacterial Treatment. T. Frederiksen. Ugesk. læger 118:739-741 (June 28) 1956 (In Danish) [Copenhagen, Denmark].

Two fatal cases of micrococcic (staphylococcic) enteritis after treatment with broad-spectrum antibiotics were observed within three months. In the first case, with a characteristic picture, the onset on the fourth day after the start of Terramycin treatment points to Terramycin as the cause of the enteritis. Death occurred on the following day. The nausea that appeared in the second case two days after the start of Aureomycin treatment was regarded as one of the ordinary complications following the administration of Aureomycin, but use of the agent was discontinued. Twelve hours later the patient's temperature had risen to 40.3 C and the clinical course was characteristic of micrococcic enteritis. The patient died three and a half days after institution of the Aureomycin treatment. In both cases cultures from the intestine showed growths of micrococcus Pyogenes var. aureus.

A Study of Hürthle-Cell Tumors of the Thyroid Gland: Report of Nine New Cases. D. C. Collins. A. M. A. Arch. Surg. 73:228-240 (Aug.) 1956 [Chicago].

Since 1907, when Langhans presented the first report, a total of 384 instances of Hürthle-cell tumors of the thyroid have been reported by 44 authors. Eleven different theories have been suggested to explain the origin of the Hürthle cell. The cell should really be called the "Baber cell," for it was Baber who first described it in 1877 and 1881. The cell is only a physiopathological variant of thyroid epithelium, representing an involutional or degenerative change. The author investigated Hürthle-cell tumors observed at the Hollywood-Presbyterian Hospital between 1924 and 1955 and presents observations on nine new instances of Hürthle-cell tumors reported for the first time. One tumor was a low-grade, well-encapsulated adenocarcinoma. Another lesion was a recurrence of a Hürthle-cell adenocarcinoma six years after a total thyroidectomy and was a single metastasis to a right cervical lymph node. The remaining seven were benign lesions, one demonstrating a Hürthle-cell reaction widely throughout a Hashimoto struma. Eight of the nine patients at a recent follow-up were alive and free from recurrence. Nine photomicrographs illustrate the characteristic histological appearance presented by each of the nine lesions. Hürthle-cell reactions do occur in various conditions of the thyroid, in a microscopically normal gland, in one with nodular nontoxic adenomas, and in the presence of Hashimoto's struma.

Most of the Hürthle-cell tumors that have been observed in the United States have been benign well-encapsulated adenomas. A more proper term for these tumors would be "eosinophilic large-celled tumor of the thyroid," as recommended by Willis in 1948. In the thyroid carcinomas characterized by a blotting out of the original histological picture by a degenerative eosinophilic change (Hürthle-cell reaction), the final degree of malignancy of the particular tumor will probably depend largely on the character of the original malignancy. It appears that a Hürthle-cell reaction in thyroid tissue indicates both a more favorable prognosis and a diminished growth capacity on the part of the original tumor. Most Hürthle-cell adenocarcinomas of the thyroid gland are rather benign and metastasize late, and then usually only into the neighboring areas of the neck. This behavior is in sharp contrast to that of the tumor originally described by Langhans, in Europe in 1907, which possesses a high degree of malignancy and metastasizes widely early in the course of the disease. Highly malignant lesions are still recorded in the current medical literature from other portions of the world. From the available American case reports collected to date, it seems that a complete lobectomy, including the thyroid isthmus, will usually result in a permanent cure of the Hurthle-cell adenocarcinoma, if it is completely removed at the first attempt. To prolong life and keep the number of recurrences of malignant tumors of the thyroid gland to a minimum, solitary nodules in one lobe of the gland should always be removed by total lobectomy including the isthmus. The practice of either cutting into a solitary adenoma of the thyroid or attempting to remove only that adenoma from a lobe is fraught with danger.

The Use of Radioactive Iodinated Serum Albumin for Blood Volume Determinations.

S. B. Marshall and K. R. McKenzie. Rocky Mountain M. J. 53:704-707 (Aug.) 1956 [Denver].

The use of iodine-131 tagged human serum albumin seems best to fulfill the requirements of speed, consistency, and accuracy. The iodinated albumin is made from salt-free human albumin and can be purchased from laboratories. Approximately 10 mg. of albumin is iodinated with 500 μc of I^{131}, or two moles of iodine to each mole of albumin of 60,000 molecular weight. It is shipped from the laboratory in 1-mc lots and contains less than 1% free iodide. The 1-mc shipment (approximately 1 ml.) of albumin is diluted to 50 ml. with isotonic sodium chloride solution, giving an initial dosage of 20 μc per milliliter. One milliliter of the diluted albumin is diluted to 500 ml. in a volumetric flask for preparation of the standard. For each determination, 0.5 to 1 ml. of the iodinated albumin (5 to 10 μc) is drawn into a calibrated tuberculin syringe and injected into an antecubital vein. The syringe is then routinely "washed out" by withdrawing blood and pushing it back into the vein. Ten to twelve minutes after injection a venipuncture is performed in the opposite antecubital vein and from 8 to 10 ml. of blood is removed in a heparinized syringe. The blood is placed in a labeled centrifuge tube, and may be analyzed immediately or after a period of several hours, since the unknown is compared to a standard having the same decay rate. Exactly 1 ml. of whole blood from the centrifuge tube is carefully pipetted into a small glass counting vial. The remaining blood is centrifuged for five minutes at 3,000 rpm, and 1 ml. of plasma is pipetted into a similar vial. A well-type scintillation counter with an attached decimal scaler is used for measurement of radioactivity. The background count is measured first, and this value is subtracted from all subsequent calculations in order to give specific activity. One milliliter of the previously prepared standard is pipetted into a third similar counting vial. Counts are then made on blood, plasma, and the standard. Blood and plasma volumes are calculated separately according to a formula.

This method was used on a group of 30 nurses, and on 30 male patients free from derangement of blood volume, in order to establish normal values. The results obtained were compared with those recorded in Denver by the Evans Blue method and with volume measurements made at lower altitudes, utilizing both the iodinated albumin and dye methods. Normal values in these four studies are presented in a table. The history of a patient with multiple contusions and a compound skull fracture is presented to show the clinical usefulness of measuring blood and plasma volume in a surgical patient by means of the method described.

Implantation of the Left Internal Mammary Artery in the Myocardium: A Histopathological Evaluation After Six Months.

R. Maniglia and A. A. Bakst. A. M. A. Arch. Surg. 73:187-191 (Aug.) 1956 [Chicago].

Maniglia and Bakst direct attention to Vineberg's experiments on the transplantation of the left internal mammary artery in the heart of dogs, which aimed at increasing the collateral coronary blood flow of the myocardium. Since Vineberg's observations were not extended beyond the 11th week, the authors made observations over a longer period. They opened the chests of nine mongrel dogs through the fifth intercostal space and dissected the left internal mammary artery off the chest wall, from the sixth to the fourth intercostal spaces. The intercostal vessels and the distal segment of the internal mammary artery at the sixth interspace were doubly ligated and transected between ligatures. A tunnel was prepared in the anterior wall of the left ventricle, and the vessel was pulled into it. The sixth intercostal vessel was transected before transplantation so that blood flowed freely from it; then it was buried in the myocardial tunnel.

Six months later the animals were anesthetized, and the chest was opened to perform physiological studies on the coronary blood. The animals were killed immediately after these studies, and the hearts were fixed in a 10% formalin solution. After fixation the myocardial tunnel containing the implanted artery was arbitrarily divided into quarters, and sections including the entire thickness of the myocardium were taken from each. Quantitative measurements of the collateral blood flow at the end of six months failed to reveal an increase in collateral circulation. This is explained on the basis of histological studies of the implanted artery showing consistent narrowing of the lumen by intimal fibroelastosis and occlusion of the lumen by thrombus.

Resection in the Treatment of Pulmonary Tuberculosis in Children and Adolescents: Report on 26 Cases.

M. A. Lassrich and F. Sturtzbecher. Arch. Kinderh. 153:201-224 (No. 3) 1956 (In German) [Stuttgart, Germany].

The authors describe observations on 26 children and adolescents who were subjected to pulmonary resection during the period from 1951 to 1954 in the surgical department of the University Hospital of Hamburg-Eppendorf in Germany. The operations consisted of a wedge excision, segmental resections, lobectomy, or pneumonectomy. The indications for these operations in 12 of the patients were pulmonary cavities that were either unsuitable for collapse therapy or had resisted such treatment. In eight children resection was necessary because of destructive pulmonary processes secondary to bronchiectasis; three children had honeycomb lung with tuberculosis superinfection, and in the three remaining patients resections were carried out because of caseous pneumonia, tuberculoma, or because of a "destroyed lung." These six different types of lesions are further illustrated on the basis of eight case reports outlining the history, roentgenologic findings, indications for resection, type of operation, and histological findings on the surgical specimen.

From 18 months to 4½ years have elapsed since the operations were carried out. All patients received sanatorium care for a period of three months after the pulmonary resection. A serious complication in the form of a bronchial fistula developed in one of the patients but was cured by surgery. All patients experienced a decisive improvement as a result of the pulmonary resection. Excretion of bacilli was arrested immediately. The patients showed improvement in general condition and an increase in weight; some of them were able to resume their occupations. This shows that the immediate results were favorable, however, more time will be necessary to estimate the final results of the pulmonary resections.

Observations on Cardiospasm and Its Treatment by Brusque Dilatation.

R. Schindler. Ann. Int. Med. 45:207-215 (Aug.) 1956 [Lancaster, Pa.].

Eighty-four patients with cardiospasm associated with distressing dysphagia were treated by brusque dilatation with the Starck metal dilator. The patient is told that the dilatation is a major operation, even though it lasts only a few seconds. The diagnosis, made usually from the typical case history and the roentgen pictures, should never be taken for granted. Obstruction by carcinoma or by scar must be excluded. The best method for establishing the diagnosis is the introduction of a thick no. 44 F. bougie. This will usually stand on the obstacle for a few seconds or minutes and will suddenly "drop" into the stomach. For the dilatation the patient is hospitalized and receives penicillin and streptomycin, and his stomach and esophagus are carefully lavaged. He should not receive sedatives, which might relax his muscles and prevent their desirable forceful rupture. After the usual local anesthesia of the throat, the dilator is introduced into the stomach and the position of its dilating portion exactly at the point of narrowing is verified fluoroscopically. At this moment the patient is told that he will feel an atrocious pain but that under no condition must he move. Then, when the patient is as tense as possible, the instrument is opened forcefully, often against a marked resistance. The operator's hand often seems to feel hard tissue broken up. If that happens, success can be predicted, although sometimes cures are obtained if this frightening sensation is not experienced. Eighty (95%) of the 84 patients were cured, and 4 (5%) were therapeutic failures. Complications occurred in five patients, three of whom had fever readily treated by antibiotics and two of whom had small lesions of the stomach. The cure of cardiospasm by brusque dilatation is usually permanent.

Two different types of cardiospasm were detected in these patients. In 81 patients the typical point of obstruction was the lowermost segment of the esophagus, extending from a few centimeters above the diaphragm to the cardia. It has been assumed that the closed segment of the esophagus constitutes a physiological entity, the "vestibulum," the border of which toward the esophagus proper contains a true sphincter muscle. This vestibulum opens only at the end of the act of swallowing, and the true picture of cardiospasm is composed of faulty, irregular innervation of the esophagus and inability of the vestibulum to open properly. The enormous resistance often felt during the act of dilatation can be caused only by a powerful muscular or tendinous organ, i. e., the diaphragm. That does not prove that the diaphragm itself is the obstructing structure. It may be that its tearing is only a by-product of the procedure and that the cure is effected by the dilatation of the vestibulum. It is probable that the essential faulty innervation remains unchanged and that the esophagus empties only by gravity. The roentgenologic appearance of the esophagus, however, often changes, so that, as far as its diameter is concerned, it resembles a normal one. Only three patients had the rare second type of cardiospasm in which the point of obstruction seemed to lie in the cardia itself. In one of these three patients no cure was obtained by brusque dilatation. There was no evidence in any of the 84 patients that cardiospasm is a purely psychogenic disease.

Effects of Pedicled Grafts of Jejunum in the Wall of the Stomach: Long Term Follow-Up Study. S. W. Moore. Ann. Surg. 144:152-158 (Aug.) 1956 [Philadelphia].

A long-term follow-up of 11 patients in whom a jejunal pedicled graft was implanted in the wall of the stomach showed no significant change in the gastric acidity as measured by the free hydrochloric acid. In 3 of the 11 patients ulcers developed in the jejunal pedicled graft. Nine of the 11 patients had poor results. Five of the nine patients with poor results had excellent results after a subtotal gastric resection.

The Hepatorenal Syndrome: A Historical Review. E. Cardi. A. M. A. Arch. Surg. 73:224-227 (Aug. 1956) [Chicago].

Cardi says that before 1913, when Marklen first used the term hepatorenal syndrome, the condition was referred to as the renal complication of obstructive jaundice. Other terms applied to this syndrome were urohepatic syndrome, hepatourologic syndrome, hepatic death, cholemic nephrosis, and bile nephrosis. Cardi discusses the historical development of the concept of the hepatorenal syndrome and of acute tubular nephrosis with special emphasis on the clinical and pathological manifestations. He reviews the extensive literature dealing with experimental studies on this syndrome and discusses the various disease states associated with it. The vascular peculiarities of the liver and kidneys are described to give a better insight into the pathogenesis of the syndrome. The review of the historical, clinical, and experimental literature leads to the conclusion that the hepatorenal syndrome is simply an acute tubular nephrosis precipitated by hepatic insufficiency.

Polyposis of the Colon. C. T. Flotte, F. C. O'Dell Jr. and F. A. Coller. Ann. Surg. 144:165-169 (Aug.) 1956 [Philadelphia].

Polyposis is a rare familial disease in which hundreds of polyps develop in the colon and rectum, usually about the time of puberty. There is a marked tendency for these polyps to undergo malignant degeneration while the patient is still relatively young. Of 63 patients with polyposis of the colon observed at the University of Michigan Hospital in the past 20 years, 40 were treated with either total or subtotal colectomy. The average age of the patient at the time the disease was diagnosed was 33.7 years. Twenty patients (50%) were found to have carcinoma of the colon at operation. Carcinoma subsequently developed in the rectal segment of four patients subjected to subtotal colectomy. Care must be taken to select for subtotal colectomy those patients who will cooperate by returning for periodic sigmoidoscopy and removal of recurrent polyps. Nineteen patients are alive and well without evidence of malignancy. Polyposis is originally a benign, although precancerous, disease, but the finding of carcinoma when the diagnosis of polyposis is first established is so common that it should always be considered as a malignant disease and treated accordingly.

Surgical Therapy in the Treatment of Diverticulosis and Diverticulitis of the Colon. M. N. Malinowski, J. E. Lutz and K. G. MacDonald. West Virginia M. J. 52:289-292 (Sept.) 1956 [Charleston].

An analysis of 66 patients admitted to the Memorial Hospital of Charleston, W. Va., between April, 1952, and October, 1955, for diverticulosis and diverticulitis is presented. The group included 36 women and 30 men, and the ages of the patients ranged from 41 to 81 years. Generally, there are three stages in the development of this pathological state, namely, the prediverticular stage characterized roentgenologically by loss of colon segmentation, the stage of formed outpouchings or diverticula (diverticulosis), and the stage of an infected diverticulum, termed diverticulitis. Of the 66 patients reviewed 39 had diverticulosis without or with only very mild symptoms. Twenty-nine patients had acute diverticulitis that responded to medical treatment. Seven patients, five of whom were women, required surgical treatment. Diverticulitis, like peptic ulcer, is treated primarily by the internist. Most patients can be managed by rest, diet, antispasmodics, and antibiotics. Surgery is required chiefly for complications, which occur in up to 20% of the patients.

The surgical treatment must be fitted to the individual patient and the type of lesion encountered. Drainage of localized peritonitis with transverse colostomy often will prove a life-saving procedure and will facilitate a fairly simple resection later on. Conservative treatment in spite of repeated, acute attacks may lead to difficult complications. Since 1950, prophylactic resection during a quiescent period has been shown to have much to recommend it and has been accomplished with little risk. This should be considered in patients in whom a persistent mass is found, and recurrent obstruction, recurrent hemorrhage, marked urinary symptoms, or malignant changes cannot be ruled out. In older persons the authors always suggest a preliminary transverse colostomy even though it requires three procedures instead of one and is more costly. In the case of obstruction of the colon secondary to diverticulitis, especially where there is a disparity in size between the proximal and the distal colon a transverse colostomy should be done.

Mesenteric Vascular Occlusion. G. S. M. Wilson and J. Block. A. M. A. Arch. Surg. 73:330-345 (Aug.) 1956 [Chicago].

Mesenteric vascular occlusion is not so rare as is generally believed. Thirty-two cases were observed in a Manchester hospital during the period January, 1948, to June, 1951. Fourteen occurred in patients under treatment in the medical wards for some other condition, and the remaining 18 patients were either treated in the surgical wards or else were seen by a member of the surgical staff in consultation. Hemorrhagic infarction has been emphasized to such an extent that most surgeons regard it as the only pathological evidence of acute mesenteric vascular occlusion. A few authors have described a type of so-called "anemic infarction," which is rare and was not observed in the cases reviewed here. The authors draw attention to another manifestation of occlusion of the superior mesenteric artery observed at operation in some of their patients. These changes were only fully appreciated in the third patient in whom they occurred. The intestine was pale, with a bluish tinge in parts, and was contracting vigorously. Blood in the lumen was visible through the wall of the intestine, and there was little if any peritoneal exudate. The mesentery itself showed no edema or hemorrhages, but it was noted that the arteries supplying the affected intestine were not pulsating. This was seen in the vasa recta adjacent to the intestinal wall, and a sudden transition to normally pulsating vessels was noted at either end of the affected segment. In another patient a correct diagnosis of mesenteric embolism was made but rejected at operation because the intestine looked "normal." This was because it was contracting actively and the mesenteric vessels were not examined closely enough in the absence of signs of hemorrhagic infarction. After autopsy had confirmed the diagnosis, it was recalled that the intestine had looked pale. The authors feel that it was only because of this unfortunate experience that the third patient was accurately assessed at operation.

They comment on venous and on combined arterial and venous occlusion and on associated pathological conditions, such as heart disease, pulmonary infarction, and multiple emboli. During the past 20 years, a number of articles have been published in continental and Latin American journals describing cases of intestinal infarction not due to organic vascular occlusion and reversible in the early stages. Various explanations have been offered—anaphylaxis, arterial spasm, and impaired capillary permeability. Divergent methods of treatment, such as the injection of epinephrine and procaine sympathetic block, have been advocated. British and North American literature is silent on the subject, but one of the authors (Block) has seen several cases of anaphylactic shock, associated with severe abdominal pain, dramatically relieved by epinephrine. All the patients in the series described eventually died. Of the 32 patients only 12 were subjected to operation, and, of these, 2 may be deemed to have technically survived the procedure. Most of the patients showed extensive infarction and serious associated lesions. In at least 75% of arterial occlusions the main stem of the superior mesenteric artery was occluded above the ileocolic branch.

NEUROLOGY & PSYCHIATRY

Cases of Atypical Poliomyelitis. C. Hooft, A. Vermassen and M. J. Delbeke. Maandschr. kindergeneesk. 24:185-192 (June) 1956 (In Dutch) [Leyden, Netherlands].

In the course of seven months a total of 178 children were referred to the authors with a diagnosis of probable poliomyelitis. In 20 of these children this diagnosis could be ruled out on the basis of clinical examination and of the results of spinal puncture and of virological examinations. One hundred-fifty of the remaining 158 patients had the classic forms of poliomyelitis; 7 had the meningeal form, 102 had the spinal form, and 41 had respiratory, bulbar, or encephalitic forms. Complete virological and serologic tests revealed the type-1 poliomyelitis virus in 94% of these patients. The authors report histories of eight children with atypical forms of poliomyelitis in whom virological examinations of the feces or antibody determinations demonstrated the viral nature of the infection. The eight children included four with temporary palsies of short duration, one with spastic tetraplegia, one with focal encephalitis without sequels, one with temporary, acute cerebellar ataxia, and one in whom poliomyelitis was complicated by meningococcic meningitis.

Poliomyelitis in Pregnancy: Effect on Fetus and Newborn Infant. M. Siegel and M. Greenberg. J. Pediat. 49:280-288 (Sept.) 1956 [St. Louis].

A prospective study was made of the outcome of gestation after the occurrence of poliomyelitis in New York City between 1949 and 1953, inclusive. During this five-year period, 87 cases of poliomyelitis were observed in pregnant women. Twenty-three of the women had the nonparalytic type of the disease, and 64 had paralytic types of the disease. The 87 pregnancies complicated by poliomyelitis resulted in 86 single births and one set of twins. There was no evidence of an increase in congenital defects and inconclusive evidence of an increase in prematurity among the 88 products of gestation. Seven (35%) of the 19 fetal deaths were observed in pregnancies complicated by the onset of paralytic poliomyelitis in the first trimester of gestation, and 14 (46.7%) fetal deaths were observed in pregnancies complicated by the onset of poliomyelitis of all clinical types in this trimester. Most of these dead fetuses were delivered within two weeks after the onset of clinical infection, and the fetal deaths appeared to be directly related to the occurrence of poliomyelitis in the mother. The incidence of fetal deaths decreased markedly with the onset of poliomyelitis in the second and third trimester of gestation.

Three cases of paralytic poliomyelitis occurred among the 69 live births. All three infants were delivered within 24 to 48 hours of the onset of neurological signs of poliomyelitis in the mother. Symptoms of paralysis in the newborn infant were observed within from 6 to 10 days after delivery. Neonatal poliomyelitis thus occurred only in infants whose mothers had poliomyelitis near term and who were born shortly after the onset of the disease in their mothers. This group is presumably unprotected by maternal antibodies and may be heavily exposed to maternal infection in the uterus, during delivery, and after birth. An increase in the neonatal mortality rate was noted that was related to neonatal poliomyelitis and to anoxemia after postmortem cesarean section in women dying of bulbar poliomyelitis.

Poliomyelitis in the Netherlands During 1955: Results of Virologic and Diagnostic Investigations. B. Hofman, A. Kret, H. A. E. van Tongeren and J. D. Verlinde. Nederl. tijdschr. geneesk. 100:2038-2045 (July 21) 1956 (In Dutch) [Haarlem, Netherlands].

Four hundred sixty-nine cases of poliomyelitis were officially reported in the Netherlands during 1955. Of 126 virus strains isolated, 37% were type 1, 57% type 2, and 6% type 3. The type-2 strain of poliomyelitis virus predominated from July to September and type 1 from October, 1955, to January, 1956. In the eastern provinces of Gelderland and Overijsel, poliomyelitis began in May and reached its peak in September, and the majority of strains isolated in those provinces belonged to type 2. In the western and southern provinces of South-Holland and North-Brabant, particularly in the region of Rotterdam and Dordrecht, poliomyelitis started in June and reached its greatest incidence in October. The greatest majority of poliomyelitis virus strains isolated in this region were of type 1. Virological studies were made in 498 patients. The percentage of isolations of poliomyelitis virus were highest (67) in the patients with paralytic poliomyelitis; for the meningeal and abortive forms of poliomyelitis the percentages of virus isolations were 17 and 12 respectively. Mixed infections of poliomyelitis with Coxsackie virus were observed in 16 patients (3.2%). Infections with group B Coxsackie virus were frequent until October, after which they decreased simultaneously with a sharp increase of type-1 poliomyelitis virus infections.

Incidence of Contact Infection in Poliomyelitis (Institutional Epidemic). H. Lennartz and B. Rohde. Monatsschr. Kinderh. 104:311-314 (July) 1956 (In German) [Berlin, Germany].

An epidemic of poliomyelitis occurred in a home housing 66 children and their nursing personnel near Bremen, Germany, in September, 1953. The children ranged in age from 3 months to 6 years. There was little contact between the residents of the home and the surrounding population, and no cases of poliomyelitis had been observed in the surroundings before the institutional outbreak. Paralytic poliomyelitis developed in 14 of the 66 children, and in one of the 14 an ascending paralysis caused death. The proportion of children who contracted poliomyelitis was about the same as that observed in other institutional outbreaks (about 20%). It was noteworthy that no purely meningeal forms of poliomyelitis occurred and that with the exception of the fatal case only the lower extremities were involved. The percentage of children with residual paralysis in the lower extremities was unusually high, that is, 12 of 13 showed such residual lesions. The authors believe that intramuscular injections during the incubation period were responsible for this. Outbreaks of whooping cough and varicella in the course of which intragluteal injections of penicillin and other drugs had been given had preceded the poliomyelitis epidemic. Moreover, five days after the appearance of the first case of paralytic poliomyelitis the children had received intragluteal injections of gamma globulin.

The fact that this epidemic of poliomyelitis occurred in children who had been isolated in an institution since birth induced the authors to investigate questions concerning the virus and its occurrence in the blood and feces of children with symptoms of poliomyelitis and in the contacts. They found that the Brunhilde type of virus was responsible for the outbreak. Virus was excreted in the feces by all but one of the children with active disease and by 80% of the apparently healthy contact children 14 days after paralytic poliomyelitis had developed in the first child, whereas virus was isolated in only two of the nursing personnel. One of these two adults was the cook, whose own child was one of the first in whom poliomyelitis developed, and the other was a 16-year-old nurses' aid. Since viremia can be expected only in the first days of infection, it is understandable that when blood was withdrawn on the 13th day after the appearance of the first case of poliomyelitis there was little promise of success. Isolation of the virus was successful in only one of 52 blood or serum specimens. The positive specimen was from a child without signs of active disease who was excreting virus in the feces but who did not as yet have antibodies against poliomyelitis. At the end of the second period of incubation the majority of children not only excreted virus in the feces but also had neutralizing antibodies in the serum. After three more weeks had elapsed, that is, at the time of the second blood withdrawal, all children showed the presence of antibodies in the neutralization test. Many showed an increase in antibodies, and the titers were rather high, although these young children had shown no symptoms of poliomyelitis. When, however, the complement-fixation reaction was carried out during the same period, poliomyelitis antibodies were not so regularly demonstrated and an increase was detected only very occasionally.

Brain Lesion After Burns. U. Huschke. Monatsschr. Kinderh. 104:300-307 (July) 1956 (In German) [Berlin, Germany].

Huschke describes observations on the brains of four children and one adult who died as the result of scalds or burns. Three of the four children died within 24 hours and one died seven days after the burn. The adult died two and one-half hours after he had fallen into boiling liquid. The ganglion cells of the brain showed all stages of acute and severe damage, which in some had progressed to complete dissolution. The Purkinje cells were in the most favorable state of preservation. The neuroglia showed mostly regressive changes, without a noticeable increase in gliacytes. Vascular changes consisted chiefly of extreme dilatation, engorgement of the veins, edematous suffusion of the vascular walls, moderate swelling and increase of the capillary endothelium, and severe dilatation of the perivascular spaces, some of them containing homogenous extravasations. The brain volume was greatly increased in all five patients (cerebral edema in three and swelling of the brain in two). This increase in volume involved the entire brain.

Disturbances in permeability with subsequent serous effusion into the cerebral tissues and new formation of intercellular glial fibers are the outstanding changes. The fibrous gliosis progresses as the interval after the burn lengthens and seems to be one of the first manifestations of brain lesions resulting from scalds and burns. The author comments on the possibility of late brain lesions, the result of which may persist after the burn has healed. It seems probable that permanent organic brain damage may progress to atrophy just as do brain lesions of other origins that are associated with acute parenchymal lesions and serous effusion into brain tissues. The clinical effects as regards mental development may be severe enough to result in idiocy.

Diagnosis and Differential Diagnosis of Wilson's Disease (Hepatolenticular Degeneration): On the Basis of Studies on Members of a Family. V. H. Gastager and W. Spiel. Monatsschr. Kinderh. 104:314-318 (July) 1956 (In German) [Berlin, Germany].

Gastager and Spiel report studies on a family with nine children. The parents showed no symptoms of hepatolenticular degeneration (Wilson's disease). The first member of the family seen by the author, in September, 1950, was a 14-year-old girl. In this patient hepatolenticular degeneration was not recognized. Psychiatric symptoms first led to a diagnosis of schizophrenia; later, neurological symptoms led to a diagnosis of a postencephalitic syndrome. A correct diagnosis was made still later in connection with the other cases in the same family. In the second patient, a younger brother of the girl, the psychiatric symptoms again led at first to a diagnosis of schizophrenia, but later, detailed neurological examinations and particularly metabolic studies permitted the correct diagnosis of hepatolenticular degeneration (Wilson's disease) to be made. A third child of the family, a boy, had died in 1937, at the age of 9 years, with symptoms of jaundice, ascites, and tumor of the spleen. According to the father, the terminal symptoms had been similar to those in the other two children. Although autopsy had not been performed in this patient, catamnestic data suggest that this too was a case of Wilson's hepatolenticular degeneration, in which the signs of congestive splenomegaly (Banti's disease) predominated. Examination of the healthy members of the family led to the discovery of one subclinical case of Wilson's hepatolenticular degeneration; in all the others, the metabolic tests were normal. The patient with the subclinical form of hepatolenticular degeneration was the youngest child of the family, who at the time of his examination was 12 years old. He was as yet free from neurological symptoms, but the liver was firm and the spleen showed signs of hardening. Moreover, the copper content of the serum indicated the presence of a subclinical form of Wilson's hepatolenticular degeneration. The studies on the members of this family revealed that Wilson's hepatolenticular degeneration generally appears in three distinct forms. The symptoms are either predominantly psychiatric, neurological, or internistic. The diagnosis of Wilson's hepatolenticular degeneration is often difficult because the psychiatric and neurological symptoms may be absent or are not typical and the Kayser-Fleischer ring of greenish pigmentation on the cornea may be absent. At autopsy the disease may be recognized by the presence of hepatic cirrhosis and by degenerative changes in the basal ganglions. The examination of the serum for a copper-containing protein is the most helpful of the laboratory aids, because in patients with hepatolenticular degeneration this protein body, which because of its blue coloration is known as ceruloplasmin, is practically absent. One of the present authors in collaboration with others has been able to detect subclinical cases in families of patients with hepatolenticular degeneration with the aid of tests that disclose a lack of ceruloplasmin.

Cerebral Palsy: Clinical Survey of 543 Cases. P. Plum. Danish M. Bull. 3:99-108 (July) 1956 (In English) [Copenhagen, Denmark].

From 1948 to May, 1956, the author examined 543 patients with cerebral palsy in the University Pediatric Clinic of the Rikshospital and treated most of them. There were more cases of quadriplegia than usual in the total material because the clinic admits a relatively large proportion of the most severely affected patients. Familial incidence and heredity do not seem to play any numerically significant part in cerebral palsy. The incidence of organic nervous disease in the group with ataxia is twice that in the other groups, which is thought to agree with the conception that ataxia is due to a hereditary trait. Pathological conditions during pregnancy are on the whole hardly of great etiological significance in the development of the disease. Toxemia of pregnancy and hemorrhage probably are exceptions and have a certain etiological significance. The age of the mother seems to be of little importance. Low birth weight is more frequent than normal in all cerebral palsy groups. Complicated deliveries occur more often than normally, particularly in the groups with hemiplegia, quadriplegia, and athetosis. Asphyxia is seen especially in patients with hemiplegia, quadriplegia, and ataxia, and symptoms during the first days of life are most common in those with quadriplegia and athetosis. Severe and prolonged icterus occurs almost exclusively in patients with athetosis. Seizures and spasms are twice as frequent in those with hemiplegia and quadriplegia as in other groups. Impairment of hearing occurs chiefly in patients with athetosis. Mental deficiency is most often met with in those with quadriplegia. In the single groups mental deficiency is higher in patients with convulsions, small head circumference, and strabismus.

PEDIATRICS

Familial Agammaglobulinaemia. R. H. Elphinstone, I. G. Wickes, and A. B. Anderson. Brit. M. J. 2:336-338 (Aug. 11) 1956 [London, England].

The authors describe two brothers with familial agammaglobulinemia. The occurrence of tuberculosis in the older brother and the behavior of the Mantoux reaction is of interest. The disease, which developed after the symptoms of agammaglobulinemia were established, ran its normal course, complicated by septic infections, and was cut short by the usual chemotherapy and antibiotic treatment. The boy's Mantoux reaction remained positive. The younger boy's case of agammaglobulinemia was discovered very early in the evolution of the disease. His serum still contained a very little gammaglobulin. He was first vaccinated with BCG before there were any symptoms suggestive of agammaglobulinemia and the Mantoux reaction became transiently positive. On revaccination the Mantoux became positive, and it has remained so for eight months. The axillary lymph nodes became enlarged, a normal consequence of BCG inoculation. The serum of all available members of the family has been examined by the zinc turbidity test or by electrophoresis. No further case of agammaglobulinemia has been found. Complete genotyping was performed, but no constant feature was discovered that could be related to the appearance of agammaglobulinemia in the two brothers. The significance of the finding of a low erythrocyte sedimentation rate requires further investigation.

Two Cases of Neuroblastoma. V. Migliori. Clin. pediat. 38:173-178 (March) 1956 (In Italian) [Bologna, Italy].

The author defines neuroblastoma as a malignant tumor of the sympathetic system with no chromogen or hormonal characteristics. It originates in the sympathetic system and may affect any area where elements of the sympathetic system tissues are found, e. g., the neck, the thorax, and the abdomen. The abdomen seems to be affected more often than other regions. Neuroblastomas tend to metastasize rapidly. They affect infants more often than adults. The tumor is made up of polymorphous cells, some of which are small and round, with little protoplasm, and with a compact nucleus rich in chromatin. The author describes two cases of neuroblastoma, one mediastinal and one abdominal. The first patient, a 9-year-old child, had severe pain in the right side of the chest; after some time changes in physiognomy appeared. The child did not have fever. Small movable lymph nodes could be palpated in the supraclavicular region. The circulatory and digestive systems were not affected. The spleen and the liver were normal. Histological examination established the diagnosis of neuroblastoma. The child was operated on, and his condition improved for a while, but then it became worse.

The second patient, a child 2 years and 8 months old, had irregular fever, shifting pains in the limbs, general indisposition, and loss of weight. Radiological examination showed a picture similar to that found in osteomyelitis, but the clinical symptoms were different. Histological examination revealed a metastatic neuroblastoma. The skull increased in volume and became irregular in shape after a short time. Bilateral exophthalmos became noticeable. A large tumor, partially calcified, was discovered in the region of the left kidney. The critical condition of the child did not permit urographic examination. The child died four months after the appearance of the condition. The author points out the necessity of early diagnosis and early surgical intervention.

Congenital Methemoglobinemia in the Newborn Period. M. S. Dine. A. M. A. J. Dis. Child. 92:15-19 (July) 1956 [Chicago].

The two cases presented are the first recorded cases of congenital methemoglobinemia diagnosed and treated in the neonatal period. They demonstrate the importance of early diagnosis for the prevention of hypoxia and death. A lavender blue cyanosis is the most marked clinical feature of this disease, in which from 20 to 40% of the hemoglobin is in the methemoglobin form, whereas the normal values are from 0.01 to 1.8%. The enzyme system that regulates the balance between hemoglobin containing iron in the ferrous state and methemoglobin containing iron in the ferric state is disturbed. The administration of reducing substances, such as methylene blue or ascorbic acid, decreases the amount of methemoglobin. Hence this feature is of value in differentiating between congenital methemoglobinemia and cyanotic congenital heart disease.

The two cases described occurred in siblings, of whom the first was treated on the 18th day of life and the second by the fourth hour of life. The diagnosis of congenital or idiopathic methemoglobinemia was established in these two children first by the identification of the typical spectral band of methemoglobin. This band disappeared immediately after the addition of two or three drops of potassium cyanide, and was thus distinguishable from the spectral band of sulfhemoglobin, which remains fixed after the addition of potassium cyanide. Secondly, the abnormally high blood methemoglobin level was reduced by both intravenously given methylene blue and orally given ascorbic acid. Thirdly, there was no history of exposure to substances capable of causing methemoglobinemia, such as contaminated well water, aniline dye in diapers, phenytoin, or coal tar. The clinical course of each infant was typical, as indicated by the fact that methemoglobinemia has persisted, though modified in degree by ascorbic acid and methylene blue. The parents and two older siblings of the patients had normal methemoglobin values. No previous instance of congenital or idiopathic cyanosis was found in the family history. Jaundice appeared in both infants, but the connection, if any, between this condition and methemoglobinemia is not known. The first child has shown marked motor retardation, probably as a result of hypoxia rather than hyperbilirubinemia; the second child has been normal in growth and development, despite severe hyperbilirubinemia requiring three exchange transfusions.

Early diagnosis of this metabolic defect is important, not only to differentiate this disease from congenital heart disease and other causes of cyanosis, but also to prevent the hypoxia that may lead to death or mental and motor retardation.

Epidemic Staphylococcal Gastroenteritis in a Newborn Nursery. R. T. Smith. A. M. A. J. Dis. Child. 92:45-56 (July) 1956 [Chicago].

The micro-organism responsible for most of the infections that occur in the newborn period is the Staphylococcus. The more serious clinical forms of staphylococcic disease usually occur during epidemic outbreaks. Serious forms of staphylococcic infection reported to have occurred during such epidemics include pneumonia, with empyema, and pyopneumothorax and generalized sepsis. The outstanding clinical characteristic of a recent outbreak of neonatal staphylococcic infection in the newborn nursery of the University of Minnesota Hospitals was an unusually severe form of gastroenteritis manifested in some of the infants. Only one previous report deals with gastroenteritis as a primary manifestation of epidemic staphylococcic infection in the newborn infant. The illness began abruptly with severe retching and vomiting in the four infants most seriously affected; in each instance, diarrhea appeared later. Each infant was found to have diminished or absent peristaltic sounds, lack of abdominal distention, and absence of normal intestinal gas patterns in roentgenograms of the abdomen. The clinical course of the four infants was also marked by the development of rapidly spreading skin lesions and epidermolysis and an unusually severe form of tetany. Mild diarrhea developed in eight other infants, and two had skin lesions.

Culture and demonstration of the Staphylococcus on gram-stained smear from stool specimens, as well as its isolation from cultures of the involved skin and nasopharynx, strongly suggested a primary infection by this micro-organism as the cause of the outbreak. The attack rate in this epidemic, which affected 12 of the 21 infants in the nursery and led to the death of one, was about 60%, and the incubation period was probably from two to four days. The source of the infection could not be definitely identified, but circumstantial evidence pointed to exposure during the first few hours of life. Early recognition of staphylococcic infection in a nursery for newborn infants is vitally important if outbreaks of epidemic proportion are to be avoided and treatment is to be properly directed.

Pulmonary Coccidioidomycosis in a Twenty-One-Day-Old Infant: Report of a Case and Review of the Literature. J. R. Christian, S. G. Sarre, J. H. Peers and others. A. M. A. J. Dis. Child. 92:66-74 (July) 1956 [Chicago].

A review and analysis of 99 reported cases of coccidioidomycosis in children is presented. Of these cases 14 were in infants, the majority of them from California. A high proportion occurred in Negroes and Mexicans, but there was no definite correlation of race and mortality. More cases occurred among boys than among girls in the preschool age group. Osteomyelitis is the commonest of a wide variety of reported clinical pictures; among the others were residual pulmonary cavity, valley fever, pneumonia, primary tuberculosis, and meningitis. The average mortality is 33%; it is higher in infants and decreases with increasing age. The diagnosis was made by direct methods, depending on demonstration of the organism (biopsy, smear, autopsy culture, inoculation) or by indirect methods (serological studies, skin tests), or both together. The duration of the disease varied from less than one month to more than one year. No truly curative treatment is known; methods tried included bed rest, general symptomatic and supportive treatment, various medicaments, deep x-ray therapy, and surgical intervention. Six of the 14 infants are known to have died.

Fatal coccidioidomycosis of eight days' duration also occurred in a three-week-old infant in Chicago. The disease was diagnosed at autopsy and the positive findings were limited to multiple nodules in the lungs. The case is unusual for these reasons: the age of the patient; the apparent contraction of the disease in Chicago, far from an endemic area; and the unusual pathological findings, this being the first reported fatal case in a child with miliary pulmonary and lymphatic lesions exclusively. The child's mother had had a coccidioidomycotic granuloma of the right calcaneus from which specific causative organisms were microscopically demonstrated. An operation was performed on her right foot in 1954 in Mexico, and the lesion now appears to be well healed, clinically and roentgenologically. It seems that the mother's lesion was the most likely source of the infection in her child.

Pheochromocytoma in an Eight-Year-Old Boy. W. van Zeben and F. J. van Sprang. Maandschr. Kindergeneesk. 24:215-225 (July) 1956 (In Dutch) [Leyden, Netherlands].

An 8-year-old boy was hospitalized in November, 1955, with a complaint of severe headaches since July, 1955. He had lost weight and was nervous during the day and restless at night. He had repeated attacks of abdominal pain, which were of the piercing type and were localized in the right upper abdomen. These attacks were followed by a headache of right frontal or occipital localization and were accompanied by anxiety, restlessness, and profuse sweating. Blood pressure reached 240/180 mm. Hg, and the pulse rate was as high as 150 per minute. The presence of pheochromocytoma was considered likely, and this diagnosis was verified with the aid of tests with Regitine (phentolamine) and piperoxan.

Preoperative localization of the tumor proved impossible, since presacral air insufflation and intravenous pyelography failed to reveal a clear outline of the adrenals. A median laparotomy revealed a tumor above the right kidney, which was then removed in the course of a thoracolaparotomy. Two months after the operation the patient was free from complaints. An unusual aspect of this case was a strongly positive Rumpel-Leede sign. There is no other report in the literature of the concurrence of this sign with pheochromocytoma.

Precocious Tetany with Periostosis and Recurring Hypocalcemia. R. Debré, P. Mozziconacci, G. Schapira and others. Arch. franç. pédiat. 13:461-476 (No. 5) 1956 (In French) [Paris, France].

The authors report a case of precocious tetany with bony lesions and recurrent hypocalcemia in an infant girl. At the age of 6 days she presented convulsive tetany of extreme intensity accompanied by hypocalcemia varying from 0.45 gm. to 0.50 gm. per 1,000 cc. This tetany was accompanied by bony lesions characterized essentially by a periosteal thickening producing the appearance of a double contour at the diaphysis of the long bones. The tetany responded to treatment with calcium, which resulted in disappearance of the crises, normalization of the blood calcium level, and improvement of the pathological bone pictures. But after one year of development, when the infant had received notable doses of calcium and vitamin D, a lowering of the blood calcium level accompanied by convulsive crises occurred again. Three months later there was another transitory hypocalcemia.

Precocious tetany with periostosis deserves a place among the causes of infantile hypocalcemic convulsions. It starts in the first months of life and progresses toward a recurrent hypocalcemia in spite of the administration of calcium and of vitamin D. This tetany is distinguished from rachitic tetany by the radiological appearance of the osseous lesions. It is also distinct from neonatal tetany, which is always transitory. It is not related to a disturbance in the absorption of calcium but is probably caused by a parathyroid insufficiency rather than a fault in the response of the renal tubule to the parathyroid hormone. It is not necessarily accompanied by the morphological disorders or the intellectual retardation described in certain varieties of chronic idiopathic tetany and in the pseudohypoparathyroidism of Albright.

Indications for Corticotherapy in the Treatment of Tuberculosis in the Child. A. Breton and B. Gaudier. Pédiatrie 11:523-530 (No. 5) 1956 (In French) [Lyon, France].

Two criteria are essential in judging the efficacy of the hormonal treatment of initial tuberculosis: (1) pulmonary x-ray films frequently repeated reveal lesional improvement; and (2) attentive surveillance of the general state shows that all treated children benefit on all the planes of the mode of cure. One notes a regression of functional signs, a rapid normalization of temperature, a certain euphoric state with a revival of appetite, and, very often, a clear rise in the weight curve, which was level or declining at the beginning of the primary infection (gains of 1 kg. per month are frequent in the course of the cure and after its cessation). These pleasing results in the general state and the indisputable regression of the lesions themselves authorize the use of corticotherapy in the treatment of tuberculosis in children. Short cures, always in association with specific antibiotics, provide protection against complications, which are rarely severe. The action of the corticoadrenal hormones as an adjuvant to antibacillary treatment will be better understood and better utilized after more experience. The tuberculous child benefits from this new method of treatment as does the adult. Four clinical forms constitute the essential indications: acute disseminated tuberculosis, recent infiltrating lesions, pleural effusions, and ventilatory disturbances engendered by endobronchitis. Among these indications serous miliary tuberculosis, certain forms of bacillary meningitis, and serous effusions are unanimously recognized. In all other eventualities and in particular during the development of the most common forms of primary tuberculosis, certain improvements can be obtained that should encourage the use of this recent and promising therapeutic agent. The advent of new antibacillary antibiotics, such as cycloserine, does not modify the authors' present therapeutic position concerning hormone therapy in any way.

Investigation of the Efficacy of Pancreatic Substitution Therapy in Cystic Fibrosis of Pancreas. W. K. Dicke. Maandschr. kindergeneesk. 24:226-233 (July) 1956 (In Dutch) [Leyden, Netherlands].

Dicke reports experiences with pancreatic substitution therapy in six children with cystic fibrosis of the pancreas. The diagnosis was established on the basis of infantilism, steatorrhea, and the results of duodenal intubation and of the determination of the amino acid content of the blood. The digestive process of children with pancreatic fibrosis is greatly improved by the administration of pancreas powder during meals. Although it might be assumed that a tablet with an acid-fast cover would be more effective for pancreatic substitution therapy than a pancreatic powder, it was found that in the children with cystic fibrosis of the pancreas a powder was more effective than tablets. Standardization of pancreas powder is essential. The general condition of children with this disorder improves greatly under the influence of treatment with pancreas powder, whereas it has proved impossible to keep them alive with antibiotics alone.

Oversize Fetuses and Their Development After Birth. B. Wennerberg. Nord. med. 56:985-987 (July 12) 1956 (In Swedish) [Stockholm, Sweden].

Of 15,017 children born between 1938 and 1953, 72, or 0.48%, were oversize, with a birth weight of 5,000 gm. (12.1 lb.) or more. The perinatal mortality was almost 10%. If the oversize infants survive the greater risks at parturition, there is no difference between their physical and mental development and that of infants of more normal birth weight, as shown by the follow-up of 59 infants oversize at birth. The parents were of normal weight and height, but in 10 of 51 cases one of the parents had been oversize at birth. There was no case of diabetes among the parents.

Hemorrhagic Diathesis in Children: Follow-Up Examination. T. Friis and P. Pacregaard. Danish M. Bull. 3:108-111 (July) 1956 (In English) [Copenhagen, Denmark].

The prognosis for hemorrhagic diathesis in children is relatively good and seems to be somewhat better in the nonthrombopenic than in the thrombopenic cases. The follow-up examination of 61 children with hemorrhagic diathesis was carried out after an observation period of an average of four and one-tenth years. Only six patients showed signs of tendency to bleeding. Three patients had died, two from hemorrhage.

Hypertrophic Pyloric Stenosis. A. Backman. Nord. med. 56:1026-1028 (July 19) 1956 (In Swedish) [Stockholm, Sweden].

Of 31 cases of pyloric stenosis treated in the children's department of the Maria Sjukhus in Helsinki from 1949 to 1955, 28 were in boys and 6 in girls. The symptoms usually set in during the second or third week of life. In most cases the diagnosis of hypertrophic pyloric stenosis was verified by roentgen examination. Medical treatment was given in 21 cases, with one death, surgical treatment in 13 cases resulted in four deaths. However, the statistics give a wrong picture, as four of the deaths occurred in 1949, when a severe epidemic of diarrhea was raging among infants in Helsinki. When the diagnosis of hypertrophic pyloric stenosis has been established, medical treatment with methyl scopolamine nitrate should be given. At the same time possible disturbances in fluid balance are to be treated. Surgery should not be resorted to unless the medical treatment proves unsuccessful and should preferably be performed in a clinic specializing in pediatric surgery.

UROLOGY

Considerations on the Therapy of Bilateral Lithiasis of the Kidney. M. Sorrentino. Riforma med. 70:729-733 (June 30) 1956 (In Italian) [Naples, Italy].

The author subdivides lithiasis of the kidney into two types, benign and malignant. Benign lithiasis is that type that does not seriously damage the kidney in which the calculi are located and whose effects on the other kidney are not grave. To the group of malignant lithiasis belong those forms that have a rapid and severe effect on the kidney in which they are located and whose effects on the other kidney are severe. Malignancy is determined by the precocity and extent of the lesions, the number of the calculi, the recurrences of the calculosis, and bilateral calculosis. Bilateral lithiasis of the kidney is a systemic disease as well as a disease of the particular organ involved. A general study from the endocrine and metabolic points of view is therefore necessary. Prophylactic therapy is always useful in order to prevent relapses even if it is not possible to detect a definite hyperfunction of the parathyroid. When radiological and laboratory researches indicate a definite hyperfunction of the parathyroid, surgical intervention is advisable. Research to determine whether a lack of vitamin A is present in the blood must always be made. The amount of vitamin A that would be considered sufficient for a normal person would not be so for a person with dysfunction of the liver. Once bilateral calculosis has been demonstrated, surgery should be performed as soon as possible with a method as adequate and as economical as possible. The author has had unexpected results even when he has operated with little or no hope of getting positive results. Nephrectomy should be performed only in cases of extreme necessity. Nephrostomy should be performed, and the calculi should be removed. In case of bilateral lithiasis the more severely damaged kidney should be operated on first. If nephrectomy becomes necessary, the more severely damaged kidney should be removed. The less severely damaged kidney is to be operated on after a length of time depending on the general condition of the patient and the recovery of the kidney that was operated on first. Medical treatment cannnot take the place of surgical treatment, but it can be complementary to it. In the postsurgical treatment the following medicines should be considered: vitamin A, small doses of insulin, drugs for the protection of the liver, liver extracts, kidney nutritive substances, vitamins of the B group, mild diuretics, and large quantities of water.

Anorchism Without Eunuchism. R. D. Amelar. J. Urol. 76:174-178 (Aug.) 1956 [Baltimore].

The case reported concerned a 19-year-old man, who was referred to a U. S. Air Force Hospital for the treatment of supposed bilateral cryptorchism. He was 71.5 in. tall, weighed 141 lb., and had a high-pitched voice. There was no evidence of testes in the scrotal, inguinal, thigh, or perineal regions. Rectal examination revealed the prostate to be small, firm, and symmetrically developed, and the seminal vesicles were not palpable. The impression was that the patient had bilateral abdominal cryptorchism. Bilateral inguinal exploration and an exploratory laparotomy established bilateral anorchism. Acrylic testicular prostheses were inserted into each scrotal cavity for their cosmetic effect. Congenital bilateral absence of the testes is generally considered as synonymous with eunuchism. The psychosexual development of this patient along masculine lines with normal male sexual urges and the ability to have ejaculations is attributed to the occurrence of extratesticular interstitial (Leydig) cells found scattered in islands along the wolffian duct structures in the patient's inguinal canals.

***The Prognostic Significance* of an Elevated Serum Acid Phosphatase Level in Advanced Prostatic Carcinoma.** E. J. Ganem. J. Urol. 76:179-181 (Aug.) 1956 [Baltimore].

A recent clinical investigation of patients with advanced prostatic carcinoma too extensive for cure by radical prostatectomy revealed that 5-year survival rate varied widely from 59% to 0% depending on the presence or absence of hydronephrosis, bone metastases, and an elevated serum acid phosphatase level. These figures applied to patients treated by orchiectomy and estrogenic hormones. The author investigated the influence of acid phosphatase levels on prognosis in 145 patients with advanced prostatic carcinoma. An acid phosphatase level of 3.1 Gutman units or more was considered elevated, and a level of 3.0 or less was considered normal. All of the patients had been subjected to bilateral orchiectomy, and this operation had been followed by treatment with estrogenic hormones. Of 84 patients with a normal acid phosphatase level, 71 did not have and 13 did have metastases; and of the 61 with an elevated acid phosphatase level 33 did not have and 28 did have metastases. The 5-year survival rate among the 33 patients with elevated serum acid phosphatase levels but without demonstrable bone or lymph node metastases was 31% as compared to the group of 71 patients with normal acid phosphatase levels without metastases in whom the 5-year survival rate is 46.8%. The author concludes that if a patient with advanced prostatic carcinoma has no demonstrable bone or lymph node metastases but has an elevated acid phosphatase level, his chance for 5-year survival is significantly less than that of a patient with a normal acid phosphatase level, provided the patient with the normal level is treated by orchiectomy and stilbestrol therapy and survives intercurrent disease. Observations on 28 patients with elevated acid phosphatase levels and metastases further revealed that an elevated acid phosphatase level in patients with bone metastases is a poor prognostic sign and indicates a shorter survival than does a normal acid phosphatase level when the accompanying treatment is bilateral orchiectomy and stilbestrol therapy.

INDUSTRIAL MEDICINE

Treatment of Methemoglobinemia. A. F. Mangelsdorff. A. M. A. Arch. Indust. Health 14:148-153 (Aug.) 1956 [Chicago].

The inhalation of the fumes or dust of the aromatic nitro or amino compounds and the ingestion of or contact by skin absorption with any of these compounds may result in a chemical change of the blood oxyhemoglobin into methemoglobin, the presence of which in the blood stream gives the patient a cyanotic appearance. In mild cases of poisoning caused by aromatic nitro or amino compounds in patients with 30% or less methemoglobinemia a preliminary method of treatment practiced at the medical department of the American Cyanamid Company in Bound Brook, N. J., consists of bed rest, sweetened drinks, advice regarding abstinence from alcoholic drinks, and watchful care. In patients with more than 30% methemoglobinemia a decision is required as to further treatment. Three illustrative cases are described in patients with methemoglobinemia of from 43 to 50%, in whom the methemoglobin blood level dropped below 10% in less than 20 hours and continued to fall, although a "watchful waiting" attitude was assumed and no additional treatment was given. In cases of this type it is, however, necessary to follow the course of the methemoglobinemia by frequently repeated blood samples in order to give additional treatment at once, if necessary.

When the methemoglobin level is above 50%, a method of treatment is used that consists, in addition to the described preliminary treatment, of the intravenous administration of 1,000 cc. of a 5% dextrose solution. Three cases of poisoning caused by *phenylhydroxylamine*, *paranitroaniline*, and *paratoluidine*, respectively, are described in patients with methemoglobinemia of from 50 to 73% whose responses to this method of treatment were characteristic in that the rate of conversion from methemoglobin to oxyhemoglobin was slightly faster when intravenously administered dextrose was used to speed up the normal reversible process. Eighteen hours were required by the "watch and wait" procedure for obtaining a methemoglobin level below 10%. Approximately the same time was required by the method of intravenous administration of dextrose for obtaining the same result, although the original methemoglobin level was higher by approximately 20%.

The case of a seventh patient with poisoning from aniline oil is described. After the preliminary therapeutic procedure had been carried out, his methemoglobin level was still 52%. Ten cubic centimeters of a 1% solution of methylene blue was given intravenously, and five hours were required to obtain a result similar to that obtained with the two other methods of treatment. Because reconversion of mild methemoglobinemia to normal usually occurs within 20 hours, no drastic treatment is necessary. Experimental work carried out by other workers has shown that the indiscriminate use of methylene blue may cause destruction of red blood cells with a resulting progressing anemia and that some of the blood pigment may become lodged in the kidney or urinary bladder. Methylene blue or other reducing compounds should, therefore, be used only in severe cases of methemoglobinemia and then with caution.

The Promazine Treatment of Alcoholism: A Preliminary Report. F. A. Figurelli. Indust. Med. 25:376-380 (Aug.) 1956 [Chicago].

Chlorpromazine is likely to induce severe hypotension, and this is especially serious in view of the unstable vasomotor mechanism of the alcohol addict. There is a definite risk of a precipitous fall in blood pressure in the acutely inebriated if more than 50 mg. of chlorpromazine is administered over a four-hour period. Parkinsonism has been observed after the continuous administration of chlorpromazine; patients complain of severe pain after intramuscular injection; and allergic cutaneous eruptions have been the source of complaints. These and other factors induced the author to try promazine (dimethylamino-n-propylphenothiazine), which is said to produce similar pharmacological effects but less intoxication than chlorpromazine. It is now realized that the chlorine radical is unnecessary for the ataractic effect.

The author presents observations on 54 consecutive unselected clinic patients (48 men and 6 women) in whom promazine was used in the treatment of alcoholism. All had been drinking a number of years. Many had been admitted on several previous occasions, sometimes as often as three or four times a year. Twenty-four had active and 16 impending delirium tremens. The other 16 were acutely inebriated. Some were noisy, belligerent, and difficult to manage; others were tremulous, nervous, and nauseated, or drowsy and stuporous, later becoming violently active. The first 13 patients received the routine treatment for alcoholism initially (laxatives, high colonic irrigations, conventional sedatives), and two were given chlorpromazine by mouth, with no results. Promazine therapy was then instituted. In 39 promazine therapy was started immediately on admission; no other medicaments were used. The dose of promazine was standardized at 100 mg. by mouth four times a day. Five of the acutely inebriated patients recovered after only two doses of 100 mg. administered over a 12-hour period (overnight). They slept soundly and were able to return to their jobs the following morning. Nine patients required three to seven doses. These, too, slept throughout the night and were discharged late the following day in condition to resume work. Thirty-one patients required from 8 to 16 doses over a period of from two to four days. Ten patients who were violently ill and suffering from severe complications required 19 doses or more. Two of these (one with Korsakoff's syndrome and one with cirrhosis of the liver), both of whom had pneumonia and asthma, remained under treatment for 10 and 12 days, respectively, after which they were transferred to other wards for further treatment of their medical problems. The average duration of acute symptoms was 2.1 days and the average hospital stay 3.3 days. There were no side-effects. All were able to return to work unless prevented by complicating illnesses. Promazine is non-habit-forming and may be used by the family physician for the care of the alcoholic at home. Alcoholism can now be treated in the general hospital and delirium tremens in the regular medical wards.

THERAPEUTICS

Palliation of Carcinomatosis with Ascites by Means of Hemisulfur Mustard (2-Chloro-2'-Hydroxydiethyl Sulfide). A. M. Rutenburg and A. M. Seligman. New England J. Med. 255:361-368 (Aug. 23) 1956 [Boston].

A preparation of 2-chloro-2'-hydroxydiethyl sulfide (hemisulfur mustard) was administered to 30 patients with inoperable cancer. Patients selected for treatment were inoperable and unsuitable for radiation or had received the maximum dose of radiation or had become refractory to further radiation therapy. Most of the patients were in the terminal stage of their disease. All had either palpable masses readily accessible to biopsy or other objective evidence of the extent of their disease such as ascites, pulmonary or skeletal metastases, or tumor cells in the peritoneal or pleural exudate. Hemisulfur mustard was supplied in solution in dry ether in sealed glass ampuls, which were stored at —10 to —20 C. The concentration in each batch of ampuls varied from 90 to 120 mg. per milliliter. At the bedside the dry-ether solution equivalent to about 100 to 400 mg. of hemisulfur mustard was withdrawn with a needle and syringe from the ampul and immediately added to 50 ml. of sodium chloride solution (0.85%) and vigorously agitated by aspiration with some air into a 50-ml. syringe. The resulting opalescent solution was then rapidly injected (within 60 seconds) through polyethylene tubing that had been inserted into the superior vena cava via the brachial vein. After the injection the tubing was flushed with sodium chloride solution (0.85%). The polyethylene tubing was kept patent by the injection of heparin.

The toxic reactions seen after treatment consisted of nausea, vomiting, malaise, and tremor. Fourteen of the 30 patients treated were temporarily benefited. The best results were achieved in patients with ovarian carcinoma and peritoneal carcinomatosis and in one patient with a mixed mesodermal tumor of the endometrium. Palliation consisted of decreased formation of ascites, decrease in size of tumor masses, decrease in pain, and increase in appetite, strength, and sense of well-being. The longest remission of symptoms observed in one patient was 29 months.

Psychoses After Barbiturate Acid Antidote (Megimide, Glutamisol). J. Kjaer-Larsen. Ugesk. laeger 118:768-773 (July 5) 1956 (In Danish) [Copenhagen, Denmark].

Psychoses after administration of Glutamisol, which have not been described previously, occurred in 15 of 50 patients treated with this agent for acute barbiturate intoxications. The psychoses resemble spontaneous abstinence psychoses and were seen mainly among misusers of barbituric acid and in some patients with long-continued acute intoxication following administration of therapeutic doses of barbituric acid, most often after large doses of Glutamisol. The psychoses are regarded as exogenic reactions provoked by Glutamisol. While benign, they were unpleasant experiences for both the patients and their families. The risk of psychosis does not constitute a decisive contraindication for Glutamisol, but calls for observance of strict indications and particularly for care in the case of misusers of barbituric acid.

Experiences with Megimide in Treatment of Barbituric Acid Intoxication. A. Louw and L. M. Sonne. Ugesk. laeger 118:761-768 (July 5) 1956 (In Danish) [Copenhagen, Denmark].

In Bispebjerg Hospital, from September to December, 1955, 24 patients, aged from 24 to 82, with grave barbituric acid intoxication were treated with Megimide given by intravenous infusion. Most of the cases were pure barbiturate intoxications. Almost all the cases were grave, as evidenced by the clinical condition and the barbituric acid content in the blood. Megimide proved to be a potent stimulant of reflex activity and respiration and an important agent for bringing the patients into a safe state. It did not shorten the duration of coma or increase the rate of elimination of barbiturate from the blood. In three cases there were light, transient attacks of tonic-clonic convulsions and in six cases transient psychic disturbances appeared from one to three days after return of consciousness. Megimide may possibly have both an antidotal effect and an effect through cerebral stimulation. It does not cause the increased blood pressure or hyperpyrexia seen on application of central analeptics and does not seem to lead to increased oxygen consumption in the brain tissue. It can therefore be regarded as a valuable addition to the agents available for the treatment of hypnotic intoxication.

RADIOLOGY

Infantile Arteriosclerosis. H. S. Weens and C. A. Marin. Radiology 67:168-174 (Aug.) 1956 [Syracuse, N. Y.].

Approximately 40 cases of infantile arteriosclerosis have been reported, but the large majority of these cases were discovered at autopsy. The authors report clinical, radiological, and pathological studies on two infants with arteriosclerosis. A boy was hospitalized at the age of 10 months because of progressive loss of weight and enlargement of the abdomen. The essential findings on physical examination were emaciation, abdominal distention, and a small umbilical hernia. Roentgenograms of the long bones revealed a delicate but widespread calcification of the arteries that was most pronounced throughout the soft tissues of the forearm and lower extremities. Hypertension was demonstrated. After discharge and improvement, the child was readmitted at the age of 16 months with edema of the lower extremities. Emaciation and abdominal distention had progressed considerably. In spite of supportive therapy, the patient died on the fifth hospital day. At autopsy the heart showed marked hypertrophy of the left ventricle. On microscopic examination, the medium-sized arteries of the heart showed a patchy calcification of the media, with intimal proliferation leading to diminution of the vascular lumina. Various degrees of fragmentation were noted in the internal elastic membrane of these vessels. The predominant cause of death in the second infant appeared to have been an intracranial hemorrhage. It remains conjectural to what extent the widespread arterial disease contributed to the intracranial complications and fatal outcome. The case showed that the arterial changes may be demonstrated on the roentgenograms of the upper extremities.

Infantile arteriosclerosis has been recognized in renal disease, hyperparathyroidism, and vitamin D intoxication. Similar arterial changes have also been noted in progeria, in which the arteriosclerotic process is associated with extensive growth disturbances and profound metabolic changes. Infantile arteriosclerosis has been observed also in children in whom no obvious etiological factors were apparent. The principal morphological changes of the arteries in these children are a disorganization of the internal elastic membrane accompanied by deposition of lime salts in its proximity. Concurrently a marked fibroblastic proliferation of the intima takes place, which may attain such proportions that the involved vascular lumen becomes markedly narrowed or even obliterated. The majority of children with this disorder were less than a year old or even newly born. The onset of symptoms was often sudden, particularly in those with severe coronary artery disease; they had cyanosis, dyspnea, and lethargy suggesting acute cardiac failure. In others, in whom there was a more subacute or chronic course, the clinical picture was largely that of impaired health with anorexia, vomiting, weight loss, and general debility. The clinical symptoms are not usually characteristic enough to permit a diagnosis of this disease entity, but the roentgen examination should make it possible to recognize the condition during life. In all cases of unexplained heart failure and cardiac enlargement in infancy and childhood, as well as in debilitating diseases of unknown etiology, calcification of the arteries should be searched for by proper radiological studies.

The Roentgen Aspects of Necrotizing Renal Papillitis. R. E. Ottoman, J. H. Woodruff Jr., S. Wilk and F. Isaac. Radiology 67:157-167 (Aug.) 1956 [Syracuse, N. Y.].

Acute necrosis of the renal papillae has been described under a number of different terms such as "renal papillary necrosis," "renal medullary necrosis," "necrotizing papillitis renis," and "Günther's necrosis." It occurs most frequently as a complication in patients with diabetes mellitus and acute pyelonephritis. Less frequently it complicates obstructive uropathy with superimposed infection. Ottoman and his associates review the roentgenologic observations reported in the literature and report their own studies on eight patients in whom they performed pyelography. The onset of complicating papillary necrosis should be suspected in any patient with diabetes mellitus or obstructive uropathy whose clinical condition suddenly becomes worse and in whom there is a decrease in urinary function and a rapid rise in the blood urea nitrogen level. Laboratory studies usually reveal microscopic or gross hematuria, albuminuria, glycosuria in the diabetics, bacilluria, frequently decreasing urinary function, and a rising blood urea nitrogen or nonprotein nitrogen level.

A film of the abdomen with the patient supine will show enlarged outlines, which, however, will also be seen in a number of other disorders. The value of the excretory urogram is limited, because of the poor renal function associated with papillary necrosis, but the process has been demonstrated with the aid of adequate lower abdominal compression. Retrograde pyelography is the method of choice. This procedure can best be relied upon to fill any fistulas or channels and to demonstrate the degree of cavitation or sequestration. As bland an opaque medium as possible should be used, with only low-grade pressure, in filling the urinary tract, so as not to precipitate necrosis within inflamed papillae. The eight patients with necrotising renal papillitis subjected to pyelographic studies showed the following roentgenologic changes: calyceal haziness or lack of sharpness; ulcerative or erosive papillary changes; intramedullary or intrapapillary, (ring shadow) sinus formation; parenchymal cavitation with communicating sinuses; amputated calyces; extruded papillae with secondary club-like papillary fossa, ureteral or calyceal obstruction, or intrapelvic filling defect; narrow infundibula, occasionally showing a "moth-eaten" margin; decreased urinary function (in the intravenous pyelogram); and enlargement of the renal silhouette. Diagnosis of necrotizing renal papillitis can be made with a considerable degree of accuracy by retrograde pyelography and more exactly by histological examination of portions of the sloughed papilla either passed in the urine or found in the bladder in the course of cystoscopy. Earlier and more frequent recognition of this complicating process will permit more prompt institution of effective therapeutic procedures.

BOOK REVIEWS

Anatomy for Surgeons. Volume 2: The Thorax, Abdomen, and Pelvis. By W. Henry Hollinshead, Ph.D., Professor of Anatomy, Mayo Foundation, University of Minnesota, Rochester. Cloth. $20. Pp. 934, with 1109 illustrations. Paul B. Hoeber, Inc. (medical book department of Harper & Brothers), 49 E. 33rd St., New York 16, 1956.

This book is an anatomic presentation of regional anatomy of the thorax, abdomen, and pelvis, designed for the student of surgery—pupil or master. The author attempts to present a mixture of classical anatomy flavored with a discussion of "those details upon which the more mature surgeon, consciously or unconsciously, bases his daily work; second, to provide for the more mature surgeon a refresher for those details which are, perhaps, slightly outside his own field of interest, and a source of ready reference to the details which, although lying in his own field, he cannot expect to keep constantly in mind." Each chapter has been organized so that it can be read as a whole or in part, depending on the surgeon's immediate requirements. Volume 1, on the head and neck, accomplished this purpose admirably; it was reviewed in The Journal (157:400 [Jan. 22] 1955).

Although the author achieves fairly well what he sets out to do, there are certain areas in which more extensive illustrations would be useful, even to the mature surgeon, especially on the subjects of the breast and the alimentary tract with reference to the lymphatic distributions in particular. He has not taken advantage of the more recent observations on the breast by Handley (1954) and the observations on the lymphatic and venous drainage of this organ as related to the radical or extended radical mastectomy. The illustrations of the trachea and bronchial tree, the pulmonary segments, the heart, and the great vessels are presented in greater detail and with more recent references than are those of the breast. The vagus nerves are discussed and illustrated, but with a few surgical features not clearly presented or well illustrated. The abdominal wall and inguinal region are well described and accurately illustrated, especially inguinal hernia, although more detailed and less schematic drawings would be useful in a few instances. The abdominal viscera and peritoneum are accurately described but lack practical illustrations bearing on surgical incisions, operative exposures to the subphrenic spaces, and the lesser peritoneal cavity, spleen, pancreas, stomach, and colon. This may be more disadvantageous to the student than to the mature surgeon. On the other hand, discussion and illustrations relative to the treatment of portal hypertension and the biliary tract are more extensive and very helpful. The blood supply to the stomach, duodenum, spleen, liver, small intestine, and colon is well illustrated. Gerota's fascia and its relationship to the kidney is discussed but unfortunately not well enough illustrated to be easily understood. Renal anomalies are extensively discussed and illustrated, as is the rest of the genitourinary tract, except for the surgical landmarks essential to identification of the ureters from various surgical exposures. The rectum is described and illustrated according to past prevailing views; the very recent British work is not included, however. The chapters dealing with the perineum, prostate, and female pelvis are adequate.

The text suffers less than the illustrations. The latter in many instances are too schematic to be as useful as required by most surgeons. Preceding the text of each chapter is a full-page illustration of the region under discussion. None of these are labeled, which limits their value largely to one of decoration. The text, too, suffers slightly by comparison with that of volume 1, for, in the extensive use of references in this volume, the author loses to some extent the basic and established principles of anatomy in the more elaborate discussion of some of the less important and controversial areas. However, the references to such works serve as useful guides to the surgeon wishing more detailed information. With the growing interest in the surgery of cancer, the surgeon often searches for a discussion and illustration of the lymph glands and the lymphatic circulation as a whole. Although the lymphatics are discussed regionally, it would be helpful if the subject were dealt with in its entirety. This book can be recommended as a reference for the surgeon, but until revised it does not equal some other similar textbooks.

A Manual of Practical Obstetrics. By the late O'Donel Browne, M.B., M.A.O., M.A. Edited and largely rewritten by J. G. Gallagher, M.D., M.A.O., F.R.C.P.I., Assistant Gynaecologist, Mater Hospital, Dublin, Ireland. Third edition. Cloth. $7.50. Pp. 265, with 203 illustrations. Williams & Wilkins Company, Mount Royal and Guilford Aves., Baltimore 2; John Wright & Sons, Ltd., 42-44, Triangle West, Bristol 8, England, 1956.

This is a compendium-type book designed for the general practitioner in Ireland. The original edition was published 20 years ago by Browne; the present edition has been revised by Gallagher. During and following World War II, there appeared in the American market numerous specialty compends, which were useful mainly as outline reviews for young men deprived of the detailed larger textbooks and for a quick "brush-up" for specialty and state-board examinations. For the American physician, these are preferable to the volume reviewed. Drugs not in common use in America are recommended by name, whereas general terms, such as a mild sedative, an antiseptic solution, a sulfonamide, or an antibiotic, would have been preferred. The single doses of pituitary extract suggested for inducing labor are far too large, and the use of seaweed tents and bougies to induce labor should be abandoned. Line drawings in reasonable number illustrate the text, but no readily discernible reason exists for showing one forceps blade applied with the patient in the lateral prone position, the other with her in the dorsal position. The book is not recommended for use in America.

Borderlands of the Normal and Early Pathologic in Skeletal Roentgenology. By Prof. Dr. Alban Köhler. English translation arranged and edited by James T. Case, M.D., D.M.R.E., Director, Memorial Cancer Foundation, Santa Barbara, Calif. Tenth edition by Dozent Dr. E. A. Zimmer. Cloth. $24.50. Pp. 723, with 1282 illustrations. Grune & Stratton, Inc., 381 Fourth Ave., New York 16; 99 Great Russell St., London, W.C.1, England, 1956.

This book is a real classic in the field of skeletal roentgenology. Dr. Zimmer, always preserving the Köhler tradition, has ably rewritten and augmented the 10th edition. The fact that this is the 10th edition and that there are translations into French, Spanish, and Italian indicates the wide significance of this work. It is difficult to conceive of any normal or variant of normal pertinent to the skeletal system that is not included here. All the conditions are well illustrated, with concise captions. The bibliography has been augmented by Dr. Case to include appropriate references to English-language periodicals. This book is a joy not only to the radiologist but also to any physician, particularly the orthopedist, interested in trauma and diseases of the skeletal system. The basic and fundamental importance of the information so completely compiled in this work cannot be overemphasized and makes the book an essential reference work for any medical library.

Physical Diagnosis. By Ralph H. Major, M.D., Professor of Medicine and of History of Medicine, University of Kansas, Kansas City, and Mahlon H. Delp, M.D., Professor of Medicine, University of Kansas. Fifth edition. Cloth. $7. Pp. 358, with 536 illustrations. W. B. Saunders Company, 218 W. Washington Sq., Philadelphia 5; 7 Grape St., Shaftesbury Ave., London, W.C.2, England, 1956.

This edition appears five years after the fourth edition. The chapter on history-taking has been placed, appropriately, at the beginning of the book. In a subject as vast as that of the approach to the patient, there are bound to be minor omissions, but, in general, this textbook covers the field adequately. The paper is good, the illustrations are well reproduced, and typographical errors are few. This textbook may be recommended.

These book reviews have been prepared by competent authorities but do not represent the opinions of any medical or other organization unless specifically so stated.

QUERIES AND MINOR NOTES

NOISE IN INDUSTRIAL PLANT

To the Editor:—*An industrial plant using hammers and forging equipment is considering an investigation of the hearing of employees. Their surgeon has asked for help in outlining a program for the examination of employees and also alleviation of some of the noise.*

M.D., Pennsylvania.

Answer.—Medical supervision of workers exposed to excessive noise involves careful examination, employee counseling, and proper job placement. Examination should be made prior to employment, periodically thereafter, and at time of termination to determine and record existing hearing loss and related disorders. Permanent records should be made. Prior to the original examination it is desirable to obtain a detailed history from the applicant, inquiring particularly into noise exposures in previous jobs as well as in military service. The medical phase of the inquiry should embrace aural pain, drainage, ear injury, surgery (ear or mastoid), head injury with unconsciousness, tinnitis, and deafness in the immediate family.

Medical examination requires more than usual attention to malformation of the external ear or canal, obstruction or drainage, perforation or scarring of drumhead and obstruction of the eustachian tube, supplemented by subjective tests of hearing acuity. Pure tone audiometry by air conduction only is used in making industrial screening tests. Screening examinations for placement purposes involve tests of hearing thresholds at the following frequencies—500, 1,000, 2,000, 4,000, and 6,000 cps. Most audiometers include frequencies of 125, 250 and 8,000 cps, but these are not essential for industrial needs. A permanent record (audiogram) should be made of each audiometric test, properly identified as to name of subject, date, and name of person giving test.

In audiometric testing, best results indicative of true hearing acuity are obtained if tests are made before the beginning of noise exposure. This would be at the start of the shift and, even better, after a week end away from work. This is due to temporary threshold shift, in which the hearing acuity is poorer after exposure to noise and better after some hours of absence from noise. Therefore, the true base line of acuity (and loss, if any) should be established under the most accurate conditions, whenever possible. The room in which audiometric testing is conducted must be as free from noise as possible, in order that some sort of standard testing conditions are established. There is little or no masking effect if ambient noise in the test room is kept below 50 db. A test room with 40 db. of ambient noise is preferable. In many industrial situations it will be difficult to find such a suitable room, and it may be necessary to construct a special room for this purpose. Prefabricated quiet rooms are available commercially.

Transfer of a worker from a non-noisy job to one that is potentially harmful should be preceded by an examination conducted with the same detail as a preemployment examination. Periodic examinations of workers are important after placement in a noisy environment. These periodic tests may be confined largely to audiometric tests for detection of early evidence of hearing damage or fatigue due to previously unsuspected sensitivity. Reexaminations should be made about 30 days after placement, to test for possible early effects of noise, and at semiannual or yearly intervals thereafter. The physician should interpret and evaluate the various medical data relating to each individual. He should determine the existence of hearing loss or pathological disorders of the ear, the need for referral to the worker's personal physician or to an otologist, the desirability of rehabilitation through the use of hearing aids, vocational or other training, and proper job placement of workers. The applicant with a detected hypersensitivity to noise should not be so exposed, whereas the otherwise qualified deaf individual would be ideal because of the absence of any possibility of further damage to his hearing.

The ideal method of preventing noise damage to the ear is by control or reduction of the noise at its source by engineering methods. This is often difficult to achieve in industry and requires the best engineering talent as well as considerable ingenuity. Noise measurement and analysis are essential steps in the control endeavor. When noise control is not feasible or is only partially successful, it may be necessary to resort to protection of the workers through the use of suitable ear plugs, ear muffs, or helmets. Personal protective devices designed to reduce the amount of noise reaching the auditory nerve also call for medical supervision. This is especially true of those devices that must be placed in the auditory canal. Sanitation and personal hygiene require that such devices be personal. In addition to advising on the hygienic problems involved, the physician may also aid in the education program that will be necessary to get full acceptance from the workers of the need for noise protection.

CONTROL OF ALGAE IN SWIMMING POOLS

To the Editor:—*What is the best algicide for use in a swimming pool? It does not have to be anything that is used repeatedly, because we usually change the water every week.*

Darius Gray Ornston, M.D., Philadelphia.

Answer.—Many chemicals are marketed for control of algae in swimming pools. Their effectiveness as algicides depends frequently on the amount used, the method of application, and the particular kinds of algae present. One of the algicides commonly used is copper sulfate, but it must be applied correctly and in the right concentration. If the algae are distributed through the water and not attached to the sides or bottom of the pool, the copper sulfate can be placed in a loose bag such as one made of burlap. The bag is then dragged or moved through the water just below the surface until the algicide has dissolved. About 2 ppm of commercial copper sulfate is sufficient to control the common planktonic algae found in many swimming pools. By applying 2.5 oz. by weight of copper sulfate for every 10,000 gal. of water in the pool, approximately that concentration is obtained. The treatment is most effective if applied before the algae become so abundant as to be visible. Where the water in the pool is changed each week, one treatment each time the pool is filled would be adequate. For control of algae attached to the walls, a treatment is applied when the pool is drained. As much of the growth as possible is scrubbed off, and then the walls are sprayed with a 5% solution of commercial copper sulfate.

The active ingredients in other algicides include such chemicals as chlorine, 2,3 dichloronaphthoquinone, quaternary ammonium compounds, rosin amines, colloidal silver, and 3-(p-chlorophenol)-1, 1-dimethylurea. Information available from local health authorities should be useful in determining the kind of algicide and the treatment permitted or recommended for swimming pools in any one locality.

MATERNAL OXYGEN AND FETAL DISTRESS

To the Editor:—*It is a common obstetric practice to administer oxygen to the mother if fetal distress develops during labor, the rationale for this being that presumably increased concentration of oxygen helpful to the fetus results. Are there any factual or experimental data to support this?*

Joseph Rini, M.D., Springfield, Mass.

Answer.—The oxygen administered to the mother is taken up by the blood plasma. The amount of increase is about 2%, but this is apparently sufficient to favorably affect the baby in utero.

The answers here published have been prepared by competent authorities. They do not, however, represent the opinions of any medical or other organization unless specifically so stated in the reply. Anonymous communications and queries on postal cards cannot be answered. Every letter must contain the writer's name and address, but these will be omitted on request.

SODIUM-FREE DIET

To the Editor —*How long a period of time may a person be kept on a complete sodium-free diet? A patient with congestive heart failure has been on a sodium-free diabetic diet for many months without any significant side effects He is taking also digoxin, 0 25 mg three times a day, aminophylline, 0 2 gm three times a day, quinidine, 0.2 gm three times a day, and potassium chloride, 10 grains twice a day If sodium chloride is so important for the physiological process, why does this man have no complications from the above-named diet?*

Julian Mowchan, M D , Oakwood, Ohio

Answer —Among animals only a few ungulate species seek salt outside the diet Some persons theorize that man should live like the great majority of animals and that the use of added salt is abnormal and even harmful When necessary, the resorptive power of the kidneys can conserve sodium so that practically none is lost in the urine, and the elimination by skin and intestine is covered by the salts of natural foods When there are excessive losses, as with profuse perspiration from heavy labor in a hot environment or, less often, with severe diarrhea, extra salt ingestion is necessary to save life Otherwise, the great mass of patients live comfortably on the most rigid sodium restriction even in hot weather The drugs mentioned will not interfere, but drastic diuretics such as the mercurials might create serious salt deficiency

ITCHING AFTER A SHOWER

To the Editor —*Immediately after taking a shower, a patient develops violent itching all over the body with no rash, lasting about 30 minutes Physical examination is negative, except for a history of allergy What treatment would be of value in this condition?*

Harry R Deane, M D , St Petersburg, Fla

Answer —A generalized itch occurring immediately after bathing may be due to a number of causes, among which may be mentioned hypersensitivity to heat, cold, type of soap used, hardness of water, dryness of skin, and time of year, especially during cold weather

Treatment should be along the following lines 1 Take an antihistamine in appropriate dosage one-half hour before bath 2 Rub mineral or vegetable oil over affected areas before bathing 3 Change temperature of water used If cold baths have been taken, change to warm If relieved, gradually take cooler baths and vice versa 4 Eliminate soap or change soap used or limit soap to areas such as groin, axillas, and feet 5 Take tub baths for a time, using water containing a soothing agent such as starch or oatmeal 6 If skin feels dry, apply twice daily an ointment containing some lanolin or similar product Hydrocortisone ointment or some similar steroid product may be used sparingly and only in severe cases

RETINITIS PIGMENTOSA

To the Editor —*Please discuss retinitis pigmentosa When senile cataracts accompany the condition should they be removed? What improvement in vision might be expected by their removal when retinitis pigmentosa has been present for many years?*

M D , New York

Answer —Retinitis pigmentosa is an abiotrophic degeneration of the outer layer of the retina (rod and cone units) that usually begins in childhood and usually, but not always, progresses unremittingly to blindness Central vision is usually retained until the last The disease has wide variation in its course and manifestations, several subtypes are included under the name of retinitis pigmentosa It is usually transmitted as a Mendelian recessive trait, but vitamin A deficiency and several toxic agents induce an end-stage similar to that of retinitis pigmentosa (iodoacetate) There is no time-tested effective treatment for it although various medicaments have been recommended from time to time, Dicumarol is the most recent of these (Leo and Lidman. *Am J Ophth* 39 46, 1955) Whether a patient will profit by removal of senile cataracts depends on the extent of retinal disease and on the maturity of the cataracts This would necessitate ophthalmologic evaluation of each case individually.

FRACTURE OF NAVICULAR AND RADIUS

To the Editor —*A 62-year-old woman was seen recently who had fallen and injured her left wrist X-ray examination revealed recent fractures of both the navicular bone and the distal end of the radius on the same wrist I have never seen these fractures occur together and can find no mention of it in the standard textbooks on fractures I am treating the wrist as though the navicular alone had been broken, since my feeling is that this bone is likely to cause more trouble*

Donald Meehan M D , Springville, N Y

Answer —If there is no displacement of the lower end of the radius, healing should take place without complications but it will require considerably more time than for a simple fracture of the radius Immobilization in dorsal flexion and radial adduction at the wrist with a light, smoothly applied, volar, molded plaster splint would be the treatment of choice The abducted thumb should be included in the splint, but the splint should stop short to permit movement at the metacarpophalangeal joints of the fingers and at the interphalangeal joint of the thumb

STABILITY OF PENICILLIN

To the Editor —*To what degree is the potency of procaine penicillin reduced by carrying vials in the physician's bag during summer? How long, in the matter of days, after having been in such a bag should a multiple dose vial of penicillin be discarded?*

M D , Ohio

Answer —Procaine penicillin in aqueous suspension is relatively stable Tests show that it does not lose significant potency after being held at 98 F (37 C) for periods of up to three months Even at temperatures of 48 C this preparation does not lose significant potency for a period of three weeks For all practical purposes, this drug may be carried during the entire summer in a physician's bag without fear of loss of significant potency However, even though little or no loss of potency occurs, this preparation may thicken after prolonged holding at high temperatures, markedly decreasing syringeability Procaine penicillin in oil with aluminum monostearate and dry procaine penicillin powder for injection are even more stable than procaine penicillin in aqueous suspension

SERUM IODINE LEVEL DURING PREGNANCY

To the Editor —*It has been said that elevated protein-bound iodine levels are to be expected in pregnancy Are data available concerning the time that this increase occurs, its variance during the pregnancy, and the rate of return to normal post partum?*

Wallace C Ellerbroek, M D , Long Beach, Calif

Answer —The normal values of serum precipitable iodine during pregnancy range between 6 2 and 11 2 mcg per 100 cc The normal range in nonpregnant women is 4 to 8 mcg per 100 cc This elevation is physiological and is noted as early as three weeks after conception It does not increase as pregnancy advances It drops to the normal range after delivery (Man and others *J Clin Invest* 30 137, 1951)

BAROMETRIC PRESSURE AND THE ONSET OF LABOR

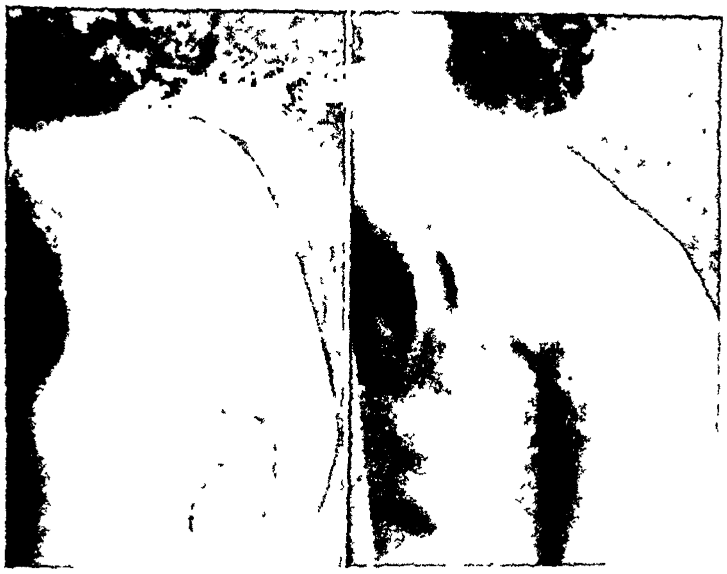
To the Editor —*Observation of many obstetric patients in two large hospitals has indicated that there appears to be some correlation between the onset of labor in patients at term and near term and a sudden marked fall in atmospheric barometric pressure Also it is known that in Leadville, Colo (2 miles above sea level), there is a high rate of premature births (highest in the United States) Surely the low barometric pressure is playing a role here Have others observed this phenomenon?*

V L Hicks M D , Kansas City, Mo

Answer —There is no proved association between a fall in barometric pressure and onset of labor. A sudden change of weather may, however, lead to a sudden apparent onset of or an increase in severity of preeclampsia and eclampsia.

TROPHIC ULCERS FOLLOWING HEAVY IRRADIATION

To the Editor:—*In reference to a query that appeared in the June 23, 1956, issue of* The Journal, *page 774, under the title of "Trophic Ulcers Following Heavy Irradiation," I wish to advise that it is not always true that skin grafting over these areas will consistently fail. We have had a number of successful cases. A woman was first operated on in 1941, elsewhere, for adenocarcinoma, grade 3, of the left breast, with metastasis to the axillary lymph nodes. This lesion had existed for one year prior to surgery. In March, 1942, she had extensive local recurrence in the axillary region in the upper end of the surgical scar, with supraclavicular nodes that extended to the sternomastoid junction making surgery impossible, even an intrascapular thoracic operation. With the patient's consent, she was given excessive deep x-ray therapy. In 1950 the irradiated areas began to break down and ulcerate, with extensive hyperkeratosis. Wide excision of involved skin was carried out at three subsequent operations with immediate skin graft. The figure shows recent pictures of the results. I am afraid that, if the query referred to above is taken literally, some patients will be denied relief of this distressing condition. I do not mean that it should be carried out in all cases, but there are certain instances where resection and skin graft can be used.*



Skin grafts of patient after excision of ulcerated skin areas due to irradiation.

TREATMENT OF CARDIOSPASM

To the Editor:—*I would like to comment on the answer to the question on treatment of cardiospasm, in the July 7, 1956, issue of* The Journal, *page 1034. The fact that the patient had cardiospasm for 20 years does not necessarily indicate that the esophagus is greatly dilated or angulated. If the organ is not angulated, unguided tubes such as Hurst dilators may be passed through the cardia into the stomach, but this seldom provides significant relief from symptoms. When the esophagus is dilated and angulated, Hurst dilators, or any other unguided instrument, will not enter the cardia but will press against the redundant wall of the most dependent portion of the esophagus, frequently at a lower level than the entrance into the stomach. Undue pressure may result in perforation of the esophageal wall.*

Esophagoscopy in a patient who suffers from cardiospasm may be a distressing procedure as a result of retained secretion in the esophagus, and if the organ is widely dilated and angulated the opening into the stomach may be difficult to identify. Even when the esophagoscope can be passed into the stomach, the degree of dilation of the cardia is seldom sufficient to provide even temporary relief from dysphagia. One dilation of the cardia with a hydrostatic dilator guided into the stomach by a previously swallowed silk thread will give complete and permanent relief from dysphagia in 75% of patients who suffer from cardiospasm. The other 25% may have occasional catching of food at the cardia and some may require subsequent dilation, but all can be given sufficient comfort so that other operative procedures are not required. Failure to relieve cardiospasm when using the Russell hydrostatic dilator indicates that the instrument was not maintained in proper position when being distended with water.

Porter P. Vinson, M.D.
Medical College of Virginia Hospital
Richmond, Va.

To the Editor:—*The reply to the question on the treatment of cardiospasm in Queries and Minor Notes in* The Journal, *July 7, 1956, page 1034, seems inadequate, in that too much emphasis is placed on mercury-weighted tubes, which are of little value, and insufficient attention is paid to more effective nonsurgical methods of dilating the cardia. Olsen and co-workers* (J. Thoracic Surg. *22:164, 1951), using metal bougies and hydrostatic bags employing pressures to 9.5-10.3 lb. per square inch, reported a satisfactory result in 60.2% of 601 patients treated with one course of dilation and 69.2% after one or more courses. Ten per cent of the patients were relieved of symptoms permanently with the use of metal bougies only. Vinson (Diagnosis and Treatment of Diseases of the Esophagus, Springfield, Ill., Charles C Thomas, Publisher, 1940) obtained similar results; subsequent dilation provided permanent relief for almost all. Esophagoscopy is rarely needed to carry out the dilation. Fluoroscopic aid may be of definite value in the location of the bag. Crump and co-workers* (Gastroenterology *20:30, 1952) use a metal dilator guided into the stomach by piano wire. It is then withdrawn to the cardia and the blades forcefully opened. The results in 72 patients were satisfactory after the first dilation in 82%. Ninety-five per cent were permanently relieved of symptoms after one to three dilations.*

The complications of the procedure, i. e., esophageal "splitting," aspiration pneumonitis, and hematemesis, are about 3%; the mortality is negligible. Except in children less than 10 years old results are comparable in all age groups. There is no relation between duration of symptoms and expected result. There is little or no relationship to the degree of esophageal deformity as seen fluoroscopically except in extreme dilation and tortuosity. No regression in the deformity can be demonstrated fluoroscopically after complete relief of symptoms; the motor function of the lower two-thirds of the esophagus remains impaired.

The experience of one of us (W. L. P.) is with the pneumatic dilator, still preferred, even though the statistical reports seem to favor the hydrostatic and metal dilators. The chief point of this comment is that the preferred and, indeed, if properly performed, almost routinely satisfactory method of treatment for cardiospasm is dilation of the cardia by the nonsurgical measures mentioned. It may be appropriate to mention that the Heller operation, although a splendid procedure when indicated, carries some element of risk. Experience has shown, furthermore, that postoperative regurgitation into the esophagus with peptic ulceration, stricture formation, and shortening of the esophagus, can develop.

Medical Care for Military Dependents • •
Jenkins-Keogh Proposal Revived for Next Congress • •
Burney Announces PHS Top Personnel Shifts • •
Foreign Service Openings for Public Health Nurses • •
Venereal Disease Program Moved to Atlanta, Ga. • •

MEDICAL CARE FOR MILITARY DEPENDENTS

By now 24 state medical societies have completed, or are in the process of, negotiation of contracts with the Defense Department for providing medical care to dependents of uniformed personnel. Society representatives bring to Washington a model local fee schedule, with at least 200 of the 700 items filled in with charges suitable to their areas. This is checked over with Defense Department officials, as are other provisions of the model contract. State societies are not required to accept all provisions of the contract drawn up by the Defense Department but are free to negotiate for any changes that would be more suitable in their particular situation.

When the program goes into effect Dec. 7, fiscal or disbursing agents selected by the state societies will be in charge of handling billings from physicians and making payments to them from Defense Department funds. To date the following state societies have completed or have started their contract negotiations: Michigan, California, Washington, Colorado, New York, Minnesota, Indiana, North Carolina, Oregon, Connecticut, Wisconsin, Massachusetts, Maryland, New Jersey, New Hampshire, Vermont, Rhode Island, Iowa, Illinois, Nebraska, and Montana.

REVIVAL OF JENKINS-KEOGH PROPOSAL

One of the sponsors of the long-standing Jenkins-Keogh proposal for establishment of individual tax-free pension plans has been laying groundwork for a revival of the legislation in the next Congress. Rep. Eugene Keogh (D., N. Y.) has written his colleagues in Congress urging them to endorse the proposal during their election campaigns. When the next Congress convenes the bill will be reintroduced, possibly with an amendment to permit a "take-down" of funds, Mr. Keogh wrote. This would permit physicians and others to withdraw money from their pension plan prior to reaching age 65, subject to a penalty equal to the taxes previously deferred on the amount withdrawn.

Mr. Keogh said it was hoped that an amendment along this line "will dissipate any remaining substantial objections to the present form of the bill, especially those originating in insurance circles." He added: "The sponsors of the legislation, including all recognized national professional associations and many other self-employed groups . . . and those who will introduce the amended bill, hope that if you are a member of the next Congress, you will support the amended bill. We think that if you make known to those professional, agricultural and business groups in your district your support of the bill, it will not only be of considerable assistance in your reelection but will assure its passage next year." The American Medical Association has long advocated passage of legislation along these lines. Mr. Keogh reports that support for the idea is growing and that he is more optimistic of action next session than at any previous time.

PUBLIC HEALTH SERVICE PERSONNEL CHANGES

Major shifts in top personnel of the U. S. Public Health Service have been announced by Surgeon General Leroy E. Burney. They are the first since he took office last August from Dr. Leonard Scheele, who is now with a pharmaceutical firm. The reassignments involve four physicians, all career officers in the PHS. They become effective Nov. 1.

Dr. Jack Masur, an assistant surgeon general in charge of the Bureau of Medical Services, is shifted to the Clinical Center in the National Institutes of Health at Bethesda, Md. Before becoming chief of the bureau in 1951, Dr. Masur was in charge of planning and construction of the 500-bed center. He entered the PHS in 1943 after serving in administrative posts at Lebanon Hospital and Montefiore Hospital in New York City.

To fill Dr. Masur's post, Dr. John W. Cronin, head of the Hill-Burton hospital construction program for the past seven years, is being promoted. Dr. Cronin has been with the service from the time he was an intern in 1932 and has had postgraduate training in psychiatry. The bureau, one of the largest in the PHS, supervises all PHS hospitals, Indian health and foreign quarantine programs, the Hill-Burton program, and dental and nursing resources activities. Dr. Van M. Hoge, now associate chief of the Bureau of Medical Services, also takes over the Hill-Burton directorship. Dr. Hoge was the first director of the Hill-Burton program when it was launched 10 years ago. He continues his duties in the bureau under Dr. Cronin. Dr. D. W. Patrick, current director of the center, will be given a new assignment as yet undesignated.

The Burney announcement stressed the importance of the Clinical Center, which was described as the "largest facility of its kind in the world for research in the major diseases of today." Present facilities are about to be expanded to permit even greater research in neurological and cardiac surgery. Dr. Burney also

has asked Secretary Folsom of the Department of Health, Education, and Welfare to approve an upgrading of the directorship of the Clinical Center so that it requires the rank of brigadier general rather than colonel. Dr. Cronin, meanwhile, will be nominated as assistant surgeon general with the rank of major general, which is required for the chief of the Bureau of Medical Services.

FOREIGN SERVICE FOR PUBLIC HEALTH NURSES

The State Department has openings for public health nurses in "most parts of the world" in its Foreign Service. They will be assigned to embassies for their two-year tours of duty, and as far as possible their wishes will be observed as to the country in which they will serve. They must have a degree with a public health major and a year's experience in some generalized public health program. For information, contact Miss Evelyn E. Weigold, Nurse Consultant, Department of State, Washington 25, D. C.

VENEREAL DISEASE PROGRAM

The government's $4,100,000 venereal disease program will be administered from Atlanta, Ga., at the Public Health Service's Communicable Disease Center, starting next February. Plans for the transfer, which will involve about 50 employees, were announced by PHS Surgeon General Leroy E. Burney. It was explained that, since venereal disease is communicable, the control program could be better operated from the disease center. The center now has a staff of over 800 persons. The latest move underscores the growing importance of the center, which now includes such operations as poliomyelitis surveillance, epidemic intelligence service, vector and rabies controls, as well as histoplasmosis and encephalitis programs.

REVISION OF BOOK ON CLINICAL CARE

The importance of encouraging your child to be creative and imaginative is stressed in a new edition of "Your Child from One to Six," one of a series of standard books for parents published by the Department of Health, Education, and Welfare. This volume incorporates recent ideas on the growth of children from infancy to school age. Whereas the last edition 11 years ago emphasized the physical care and health of the child, this version concentrates on the mental, social, and emotional development.

In the main part of the book thumb-sucking, shyness, and slow physical development are placed in proper perspective. The main thesis is that a child in this age group is an individual and will have his own course of development and his own reactions to situations. Parents can help the child by understanding him as an individual and by giving him the needed confidence, discipline, and love.

The medical section of the bulletin, revised by Dr. Marian M. Crane, chief of the research interpretation branch, discusses first the importance of regular examinations by the doctor. The mother can facilitate these examinations if she is prepared to answer questions on the child's eating, sleeping, and play habits. Another suggestion is to keep a record of your child's bruises, falls, and cuts.

The remaining part of the medical section is concerned with the prevention of disease. The bulletin lists the precautions necessary to avoid contracting such diseases as influenza, tuberculosis, dysentery, and roundworms. Good health routines, immunization plans, and sick room procedures are outlined carefully. In the final pages the symptoms and course of various childhood diseases are discussed. The bulletin is available from the Superintendent of Documents, Government Printing Office, Washington 25, D. C. It is priced at 20 cents a copy.

PERSONNEL

Brig. Gen. Wendell H. Duplantis is the new assistant administrator in charge of Operation Control Services, the nerve center of the Federal Civil Defense Administration. He retired from the Marine Corps last month after a career of 21 years. . . . James E. Webb is a new member of the National Advisory Cancer Council, which advises on research activities of Public Health Service's National Cancer Institute. . . . At the 63rd annual meeting of the Association of Military Surgeons medical awards will be presented to Col. Eugene C. Jacobs, Army; Capt. Robert S. Poos, Navy; Dr. George M. Lyon, Veterans Administration; Lieut. Col. Edwin J. Pulaski, Army; and Capt. Elinor Pearson, Army.

Familial Leptocytosis.—Familial leptocytosis, thalassemia, or Cooley's anemia is apparently an ancient disease. Anthropologic studies indicate it may have been present in Sicily in paleolithic times. However, it was first identified as a separate entity by Cooley and Lee in 1925 and again by Cooley, Witwer, and Lee in 1927. They described a series of cases of anemia with splenomegaly and peculiar bone changes occurring in children of Greek, Italian, Syrian, or Armenian descent. . . . A review of the existing Italian literature indicates the following pathogenesis of leptocytosis. A spontaneous mutation of the red cells occurred in the ancient race about the Mediterranean Sea, which inserted itself in the ethnic structures of some countries (mainly, Italy and Greece). The inherited defect consists of a morphologic alteration of the red blood corpuscles. The cell is formed with an adequate or excessive membrane, which contains little hemoglobin substance, so that the cell appears to be thinner (leptocyte) and of a smaller volume (microcyte) than the standard normal red blood corpuscle. As a result such a red blood corpuscle shows an increased resistance to hypotonic saline solution. It also possesses a life span of shorter duration than the normal cell which in vivo results in corpuscle losses. This condition causes a chronic stimulation of the bone marrow with medullary hyperplasia of the erythroblastic series. Immature cells showing stippling, polychromatophilia, and erythroblastosis appear in the blood. The bone marrow becomes hyperactive (erythroblastosis), and osteoporosis occurs (x-ray observation), as well as splenomegaly. Erythrocytes, together with leptocytes and microcytes, and the increased resistance to hypotonic saline solution make up the features of the peripheral blood picture.—P. R. Casesa, M.D., Familial Leptocytosis, *New York State Journal of Medicine*, May 15, 1956.

'LANOXIN' continues to offer the same advantages — only the name has been changed.

The full effects of each dose develop quickly to permit rapid appraisal of the need for additional drug. Moreover, the limits of the patient's therapeutic range, which may be reduced in the seriously ill, may be approached with relative safety because toxicity, if it develops, soon abates. For true balance and uniformity of therapeutic effect, prescribe 'LANOXIN' brand Digoxin.

Sincerely,

'B. W. & Co.'

VISUAL INTRACARDIAC SURGERY IN A SERIES OF ONE HUNDRED ELEVEN PATIENTS

Henry Swan, M.D.
and
S. Gilbert Blount Jr., M.D., Denver

• *The use of general hypothermia in order to permit cardiac surgery to be performed on the open heart with a dry field under direct vision has intrinsic, unknown risks. These have been analyzed in 111 patients, the largest group being 58 patients with atrial septal defects. Of 19 fatalities, 8 were due to cardiac failure, 4 to thrombosis, 4 to hemorrhage, and 3 to other causes. The hazards both of the cardiac arrhythmias and of the disturbances of clotting can be greatly reduced by not exceeding a limit of eight minutes of circulatory occlusion, by not using this technique for procedures that cannot be readily accomplished within this time limit, and by keeping the temperature within the range from 29 to 32 C (84.2 to 89.2 F). Within these limitations, pulmonary valvular and infundibular stenosis, atrial septal defect, and aortic stenosis can be readily repaired at low risk. The risk is justified by the sometimes dramatic improvement seen after operation in patients with otherwise hopeless conditions.*

This report is concerned with an analysis of our clinical experience with one method (hypothermia) for achieving the major goal of cardiac surgery; namely, open heart, dry field, and direct vision. Deep is our conviction that from the surgical point of view increasing experience will enable most if not all current and future operative procedures within the heart to be accomplished with deliberation under these conditions. By one technique or another, the risk to the patient will be as low or lower and with better results than current blind manipulations guided only by the sense of feel. Surely the accuracy that vision gives to technique, together with the versatility it allows in coping with unexpected variants of the defect, will effect results that are superior from all standpoints. This is already true of valvular and infundibular pulmonary stenosis, atrial septal defect, and ventricular septal defect. We believe it will eventually be true of all intracardiac procedures.

In the exploration of any new technique, however, though the successes be gratifying, the way is strewn with occasional bitter defeats that seem doubly difficult to accept as one realizes that increasing knowledge and experience will probably prove that many such failures would later be preventable. Yet, thus it is with all clinical exploration of new horizons, and one seeks strength in the conviction that in each patient the diagnosis was as certain as possible, the need for surgery was definite and urgent, and the background of experiment was as broad as possible. Not all the questions, however, can be completely solved in the laboratory; in the end, clinical trial must be made and the vital human problems faced.

The operations performed in this series of patients were all done during general hypothermia. The methodology of our management of hypothermia has been described in previous publications,[1] and will not be elaborated here. Moreover, the actual operative techniques have also been described,[2] so these will not be further discussed. We are primarily concerned here with the results of the procedures. When one is utilizing a new modality such as hypothermia, with its intrinsic but unknown risks, and then superimposes in addition a new technical method, such as open suture closure of atrial septal defect, open pulmonary or aortic valvuloplasty, or suture closure of ventricular septal defect, one may have difficulty in assessing the reasons for success or failure in a single patient. We have attempted to evaluate our results in spite of the complexity of the variables.

From the departments of surgery and medicine, University of Colorado School of Medicine.

when you say no salt
put zest into patients' food
with co-salt

Patients will never miss table salt when they season foods with fine, white, free-flowing Co-Salt...because Co-Salt tastes so much like salt it's hard to tell the difference. Looks like salt, sprinkles like salt. With Co-Salt, patients follow your diet more faithfully... and thus are better nourished. Used directly on food or in cooking.

co-salt

sodium-free salt substitute

contains no sodium, no lithium...is not bitter, disagreeable, or metallic in taste,

ingredients: Choline, potassium chloride, ammonium chloride and tri-calcium phosphate.

supplied: 2 oz. shaker top package
8 oz. economy size

send for samples.

postoperative physiological studies reveal that 15 of these 17 patients have achieved a cure, which we have arbitrarily defined as a postoperative residual systolic pressure gradient between the right ventricle and the pulmonary artery of 20 mm. Hg or less. In the 17 patients recatheterized, a systolic pressure gradient of less than 10 mm. Hg was noted in 9 patients and less than 20 mm. Hg in 6 patients. In the remaining two patients there were gradients of 26 and 28 mm. Hg. Diastolic pulmonary artery pressures have remained normal, and significant pulmonary regurgitation has not occurred in any patient. Although this series is still relatively small, it is our conviction that this current operative approach is a both safe and eminently effective one and is superior to the blind transventricular approach.

Infundibular pulmonary stenosis with an intact ventricular septum is a relatively rare congenital lesion. However, in this series such lesions have been evaluated in two patients, and resection of the infundibular stenosis performed. It is often difficult to be certain from the physiological studies as to whether the ventricular septum is intact, for oftentimes, although no shunt in either direction is definitely established, postmortem examination may reveal the presence of a small defect in the ventricular septum. However, when the stenosis is established as being in the infundibular area, there is no physiological evidence of either a left-to-right or right-to-left shunt at the ventricular level, and the right ventricle is hypertrophied with an elevated pressure, then surgery is definitely indicated. Since there is no defect in the ventricular septum, the surgeon can remove the area of infundibular stenosis completely without concern for the abrupt development of a significant left-to-right shunt after the removal of the infundibular stenosis.

Table 2.—*Results of Surgery in Patients with Atrial Septal Defects*

Disease	Patients, No.	Operations, No	Proved Total Cure	Improved	Unimproved	Dead	Too Recent to Evaluate
Atrial septal defect (secundum)	45	46	26	9	0	7	3
Atrial septal defect (primum)	1	1	0	1	0	0	0
Hiatus atrioventricularis communis	3	3	0	0	1	2	0
Atrial septal defect and pulmonary stenosis	9	10	1	4	0	2	2
Total	58	60	27	14	1	11	5

Table 3.—*Results of Surgery in All Patients with Pulmonary Stenosis*

Disease	Patients, No.	Operations, No.	Total Cure	Improved	Unimproved	Dead	Too Recent to Evaluate
Valvular stenosis	25	25	15	7	0	0	3
Infundibular stenosis	2	2	1	1	0	0	0
Trilogy	9	10	1	4	0	2	2
Tetralogy, infundibular	10	10	0	7	0	3	0
Tetralogy, valvular	7	7	0	7	0	0	0
Total	53	54	17	26	0	5	5

The two patients in this series considered to have had this anomaly have both had excellent results, and one is considered cured. Thus, in one patient the systolic pressure gradient between the right ventricle and pulmonary artery was completely abolished, and the postoperative studies revealed no evidence of a shunt in either direction. The remaining patient, completely asymptomatic, had a postoperative pressure gradient of 27 mm. Hg. Again, the currently suggested approach to this lesion is considered to be both safe and effective.

The indications for surgery in the patient with trilogy of Fallot are in general similar to those for valvular pulmonary stenosis with intact septums. Patients falling into this group usually, although by no means invariably, have a higher systolic pressure within the right ventricle, and, thus, almost always the indications for surgery are clear-cut. Early in our experience we had hoped that, with the regression of the right ventricular hypertrophy after valvuloplasty and the change in the pressure-volume relationship of this ventricle, the right atrial pressure would fall, the right-to-left shunt would be abolished, and possibly the foramen ovale might close, should that have been the defect in the septum. The follow-up course on some of these patients has not been sufficiently long as yet to prove or disprove this hypothesis. However, it would appear that in some of these patients the defect in the atrial septum will remain open and that a second operation for closure of the defect may be necessary, whether it be a dilated foramen ovale or a true atrial septal defect.

We have operated upon nine patients who fall into this category, with two deaths. One patient, 7 months of age, who had been very cyanotic, with a peripheral arterial saturation of 49%, died suddenly 14 hours after surgery. The operation and immediate postoperative course until time of death were uneventful. The other mortality was in a 19-year-old boy with a preoperative right ventricular systolic pressure of 175 mm. Hg and who was very cyanotic, with a peripheral arterial oxygen saturation of 74%. The valvular pulmonary stenosis was relieved without event; however, it was then decided to close the defect in the atrial septum, which was found by palpation to be of great size. The patient developed ventricular fibrillation before the atrium could be opened, and, although a normal sinus rhythm was finally established, the patient died six hours later. One patient on whom both pulmonary valvuloplasty and repair of atrial septal defect were done is now cured. The remaining four patients have all been greatly improved from the clinical viewpoint. Three have been catheterized postoperatively, one with complete obliteration of the preoperative right ventricle–pulmonary artery systolic pressure gradient. The remaining two had marked hypertrophy of the right ventricle and residual gradients of 33 and 31 mm. Hg.

The indications for resection of infundibular stenosis in the patient with a tetralogy of Fallot are less clear. However, in general, our experience has been that these patients are very significantly improved, and the improvement is certainly of an order equal to the anastomotic procedures of Blalock or Potts. However, the extent of the removal of the infundibular stenosis must be carefully judged, for, should the stenosed area be completely removed in the face of a large ventricular septal defect, dire consequences may result. With such complete relief of obstruction to outflow from the right ventricle, a large left-to-right shunt may be suddenly established, with resulting dilatation of the heart with myocardial failure or aneurysmal dilatation of the thin-walled infundibular chamber.[3] Thus, it is not considered wise to remove completely the stenosed area in these patients. Our results have in general been good with this procedure. The pulmonary artery pressure rises, and the pulmonary blood flow increases greatly. However, the right ventricular systolic pressure usually remains of the same order of magnitude as preoperatively. In general, then, removal of infundibular stenosis in the presence of a ventricular septal defect calls for partial excision. Total excision may result in great cardiac enlargement and congestive failure.

TABLE 4.—*Total Deaths in 111 Patients by Disease and Cause*

Disease	Hemorrhage	Postoperative Thrombosis	Cardiac Failure	Other
Atrial septal defect	1	4	2	
Hiatus atrioventricularis communis			2	
Trilogy	1			1 (Sudden death at 12 hr., cause undetermined)
Ventricular septal defect			4	
Tetralogy	1			2 (Transfusion anuria, death at 3 wk. of sepsis) (Postoperative aneurysm of right ventricle, died at attempted repair 3 mo. later)
Anomalous pulmonary veins	1			
Total	4	4	8	3

In 17 patients an open direct operative approach has been aimed at the pulmonary obstruction. Seven have had valvular obstruction and 10 infundibular. There have been no deaths in the first group and three in the second group. All patients have had marked improvement from the clinical standpoint, the cyanosis has disappeared or lessened to a striking degree, and their tolerance of exercise has been dramatically increased.

The patient with an atrial septal defect of the secundum type represents, in general, an ideal candidate for closure by direct vision during hypothermia. Although our criteria for operative intervention are still in the formative stage and will doubtless be altered as experience dictates, at the present time closure of a secundum type defect is being advised in all patients with a pulmonary index 2.5 times or more the systemic and in whom the total pulmonary vascular resistance is less than 350 dynes/seconds/cm.[5] Once again, there is no set figure for flow or resistance that can be considered as a rigid limit, and the over-all clinical evaluation of the patient remains of the utmost importance. However, it has been our experience that, in those patients with a pulmonary vascular resistance above 350 dynes, the risk of the operation has been great and the postoperative course has been complicated. Certainly, whenever possible, closure of the atrial septal defect should be urged and performed on children between the ages of 3 and 12 years, since, during this age period, the risk of the operation is least and the gain to be expected from operation is greatest. At the present time, 45 patients with atrial septal defects of the secundum type have been operated on, with 38 survivors. At surgery it was found that four of this number had, in addition, anomalous pulmonary venous connections to the right auricle or superior vena cava. In the last three of these patients, the defect was closed in such a way that drainage from these veins was into the left atrium at the completion of the closure.

Twenty-seven patients have been recatheterized following surgery, and it is considered that 26 have been cured, since complete obliteration of the previously existing shunt was demonstrated. In two patients there was a small residual left-to-right shunt. The first was the initial patient encountered with one pulmonary vein from the right lung entering the right atrium, and no attempt was made to alter the site of drainage when the atrial defect was closed. The remaining patient had a huge defect (7 cm. by 5 cm.), and, at that time, closure was being effected by interrupted sutures. It is assumed that a small opening between sutures has persisted. Clinically, however, this patient has experienced a very dramatic improvement. Currently, a continuous suture is used. This experience leads us to the conclusion that closure of atrial septal defect of the secundum type by this method is reasonably safe and is a curative procedure.

Our experience with a direct vision transaortic approach to aortic valvular stenosis is still limited. We believe that, even under conditions of direct vision, in the older age group when the aortic valve is markedly calcified and deformed, operative intervention offers relatively little except in rare instances. Ideal candidates are the young patients with congenital aortic valvular or subaortic stenosis or the patients below 40 years of age with acquired rheumatic disease but without evidence of calcification of the valve. To date, the open operation has been performed in three patients, one with rheumatic stenosis of the aortic valve and the remaining two with congenital aortic disease, valvular in one and subaortic in the other. There have been no deaths, and the operative and postoperative course has been uneventful. It is felt that the accuracy of the visual procedure will help prevent the production of aortic regurgitation, a lethal complication of the blind technique.

Cause of Deaths

An analysis of the cause of death in this series is illuminating and in a sense encouraging, since it seems likely that current techniques will afford considerable safeguard against at least two of the major causative factors. Table 4 records the deaths by cause. The cause of death was most frequently cardiac in nature—in four patients irreversible arrhythmia and in four others failure of the heart to tolerate the combined insult of a major operation and the attending manipulation, the hypoxia of circulatory arrest, and at times the additional trauma of resuscitation. These particular complications will be largely avoided by using our current temperature levels, since almost all fatal arrhythmias occurred below 28 C (82.4 F) or in connection with prolonged occlusion times.

The probable tolerance of the heart for surgery can largely be predicted. Therefore, the selection of patients for operation can greatly modify the over-all outcome in this regard. However, except in the face of circumstances that place the patient in a category that must be accepted as inoperable (for example, marked elevation of the total pulmonary vascular resistance or intractable cardiac failure), we will continue to offer operation to the desperately ill, even though it is realized by all concerned that there is a very significant operative risk involved. The risk without surgery in these patients, however, must be considered to be 100%.

The other major fatal complication was a disturbance in the clotting mechanism, either tendency to bleed excessively during surgery or intravascular thrombosis occurring in the postoperative period. These are both, in all probability, risks inherent to any operation during hypothermia. As regards the bleeding tendency, operation, hypothermia, and multiple blood transfusions are the ingredients, and each may play specific roles. A bleeding tendency (coagulation defect) in cyanotic cardiac patients undergoing surgery at normal temperature has been recognized.[4] Experimental alteration in the concentration of the formed elements of the blood and in the clotting mechanism during hypothermia has been widely noted.[5] The influence of multiple transfusions of stored blood on the bleeding diathesis is also well documented. Again however, current practice offers much hope that the incidence of this complication can be reduced. No patient whose body temperature was above 28.5 C (83.3 F) manifested this tendency to bleed excessively (coagulation defect). We believe the limitation of the degree of hypothermia to the 29 to 32 C (84.2 to 89.6 F) range, together with the use of fresh blood rather than stored bank blood, will essentially eliminate this problem.

Thrombosis

As regards thrombosis, the nature of the malformation itself may play a definite role, since it has occurred only in patients with atrial septal defects. In two patients with large shunts and massive enlargement of the pulmonary vascular bed, pulmonary venous thrombosis occurred, once on the fourth day and once on the eighth. We believe that the sudden reduction in the rate of pulmonary blood flow that occurs at the time of closure of the defect in these patients may set the stage for this complication. Currently, therefore, we are heparinizing postoperatively all adults with this disease. The other two episodes, one thrombosis of a cerebral artery on the second postoperative day and the other thrombosis of both jugular veins on the night of surgery, remain unexplained, although avoidance of any constriction in the neck during anesthesia is currently being emphasized. In general, it is believed that, by staying within our current limitations of the technique, one may expect a marked reduction in the occurrence of both cardiac arrhythmias and the disturbances of clotting mechanism.

Summary

In 111 patients who underwent open heart, dry field visual surgery during hypothermia, a large variety of congenital defects was repaired. We have come to believe that the optimal temperature level is the range of 29 to 32 C (84.2 to 89.6 F) and that avoidance of lower temperatures will largely eliminate two of the major complications, namely, cardiac arrhythmias and disturbances in the clotting mechanism. At this temperature, we believe that six minutes of circulatory occlusion is safe and eight should not be exceeded. Within these limitations, pulmonary valvular and infundibular stenosis, atrial septal defect, and aortic stenosis can be readily repaired at low risk. The eminently satisfactory results of open operation in these diseases make an eloquent plea for a broader adoption of open heart techniques.

Addendum

Since the time of this study, 19 additional patients have undergone operation without loss of life. Thus, at a temperature range of 30 to 32 C (86 to 89.6 F), there has been only one death in the last 30 patients undergoing open operation for pulmonary valvular stenosis, aortic valvular stenosis, or atrial septal defect. As currently employed, open operation during hypothermia for these conditions should present a risk of less than 5%.

4200 E. Ninth Ave. (20) (Dr. Swan).

The experimental background of this clinical series was supported by grants-in-aid from the U. S. Public Health Service and the American Heart Association and by a contract with the Office of the Surgeon General, U. S. Army.

CUTANEOUS SENSITIVITY REACTIONS TO CHLORPROMAZINE

J. Fred Mullins, M.D., Irvin M. Cohen, M.D.
and
E. Stanley Farrington, M.D., Galveston, Texas

- *Eighty-five patients manifested skin eruptions while being treated with chlorpromazine. While 57 of these had generalized reactions, almost all types of cutaneous eruptions occurred, with the exception of mucous membrane involvement. Dosage in these cases averaged 400 mg. or more a day. The lesions disappeared when the dosage was decreased or discontinued.*

Patch tests indicate chlorpromazine to be a primary irritant when applied full strength and may be of little value in determining potential reactors to systemic administration of the drug.

Among the many new tranquilizing-type preparations that have become commercially available within the past few years, the one that seems to have gained the most widespread use is chlorpromazine. This preparation is not unlike other effective drugs, in that after its use certain side-reactions or idiosyncrasies may develop. Some of the untoward reactions or complications that have been reported are orthostatic hypotension, obstructive jaundice, Parkinsonism, toxic delirium, asthmatic attacks, agranulocytosis, and numerous forms of skin reaction.[1] Lewis[2] has dealt primarily with skin manifestations, and others have reported dermatitis as a side-reaction.[3] The purpose of this paper is to describe the various cutaneous reactions that may result from the administration of chlorpromazine. An effort will be made to evaluate the use of the patch test in determining the presence of factors of primary irritation and sensitization and the value of this test in predicting susceptibility.

Material and Method

Our series consists of 85 patients manifesting skin eruptions due to chlorpromazine. It does not include approximately 200 other patients who have been observed but on whom records were inadequate for purposes of this study. Fifty-seven patients presented some type of generalized reaction. This group can be subdivided according to the following reactions: erythematous morbilliform with edema, urticarious, seborrheic, purpuric, papular, bullous, and miliaria-like. In the group of 18 patients with cases characterized by photosensitivity, the majority of the lesions were of an erythematous papulovesicular type, with one a severe bullous eruption. These lesions appeared only at the sites that were exposed to sunlight and occurred predominantly during the extended summer season characteristic of this geographical area. In 10 cases attributable to contact with the drug, the lesions were found predominantly on the dorsa of the hands and flexors of the elbows, neck, and face. The reaction was a typical erythematous eczematous dermatitis, which one would expect with an allergenic contactant. The majority of the patients in this series were given patch tests with full-strength solutions (25 mg. of chlorpromazine per cubic centimeter) by the closed and the open methods. In addition, volunteers were given patch tests with various concentrations by open and closed methods in an attempt to determine the primary irritant quality of this preparation.

Results

As can be seen in the table, this preparation can produce almost every type of cutaneous reaction. It is interesting to note that no mucous membrane lesions were observed in any of the patients studied. Of the subjects having generalized cutaneous eruptions, 35 of the 47 were females. With the exception of two cases, skin reactions did not appear until the dosage reached 400-600 mg. of chlorpromazine per day. During the hot summer months many of these subjects demonstrated a sweat gland obstructive reaction in the form of a miliaria-like eruption. The majority of eruptions were of the miliaria crystallina type; however, some of them seemed to have deeper obstruction of the sweat pores. Patch tests applied to these individuals showed that the full-strength solution gave positive reactions, but in most instances they were of the delayed type. In view of these findings, patch testing would appear to be of relatively little value in determining whether chlorpromazine was the responsible agent. As is shown below, this conclusion was confirmed by results obtained from routine patch testing of volunteers.

Total daily dosage, which ranged from 50 mg. to 1.2 gm., played little part in the production of photosensitization reactions. The highest percentage of eruptions in this category were of the papulovesicular variety and occurred at the sites of exposure. One severe bul-

---

Read before the Section on Dermatology at the 105th Annual Meeting of the American Medical Association, Chicago, June 12, 1956.

lous eruption appeared within two hours after a 20-minute exposure to sunshine. The lesions produced by photosensitization, with the exception of the single bullous reaction, were deep-seated, indicating that the site of disturbance was probably in the upper cutis. A considerable degree of brawny-type edema was associated with these lesions. It is well known that the wave lengths of summer sunlight differ from those of the winter.[4] Although this study was not specifically concerned with the effect of particular light wave lengths in the production of these dermatoses, the higher summer incidence is strongly suggestive that this difference may be a major factor.

The results of 48-hour patch tests utilizing the full-strength solution in 557 volunteers show: 79 individuals gave 1+ reactions, 36 showed 2+ reactions, 6 had 3+ reactions, and 2 gave 4+ reactions. There were 32 who gave a 1+ to 3+ reaction in a delayed manner, the reaction appearing about the fifth to seventh day. No reactions were observed in 402 subjects.

In an additional group of 845 individuals who had multiple test concentrations applied, some had three types of tests: full-strength closed, full-strength open, and 10% closed. In others, combinations of only two of these tests were used. A total of 114 had positive reactions. There were 101 positive reactions in 338 test subjects who received the full-strength closed patch test. Nine positive reactions were seen in 218 patients receiving the 10% closed patch test, and there were four positive reactions in the 289 individuals given the full-strength open test. In two instances paradoxical reactions occurred in which the individual reacted to the more dilute solution or open test but did not react to the full-strength closed test. This group also contained a number of subjects with delayed reactions.

Skin Reactions to Chlorpromazine from Systemic Use

Type Reactions	No of Cases	Dosage Range, Mg./Day	Mean Dosage, Mg./Day
Erythematous morbilliform	47	200-2,400	800
Photosensitization	18	50-1,200	200
Urticarious	7	200-1,200	500
Petechial	2	700	700
Bullous	1	400-800	600

Ten cases of contact dermatitis resulting from the subjects having worked with chlorpromazine were found. In a majority of instances the subjects were nurses or hospital employees who were required to handle this preparation as part of their duties. As would be expected, the principal sites of reaction were the dorsa of the hands and flexors of the arms, face, and neck. These lesions, which appeared from two to eight weeks after contact, were rather recalcitrant to the usual methods of therapy and resembled other types of allergic epidermal contact dermatitis. Although the degree of reaction varied with the concentration of the patch test, all these persons demonstrated flare-ups of their contact areas after the patch test procedure. Three of these patients showed a delayed type of reaction, particularly if their previous dermatitis had completely cleared. It was believed that the contact region was aggravated by sunlight, although at this time we do not have adequate statistics to support this finding. Some of the volunteers demonstrating delayed patch test reactions associated appearance of a reaction with exposure to sunshine.

Comment

There are many features about the cutaneous reactions to chlorpromazine that are a decided variation from those to other systemically given medicaments that produce skin reactions. First, the reactions produce a minimal amount of symptomatology as compared with other drug eruptions. Second, these reactions clear quite rapidly in a period of two to five days when therapy is discontinued. Once the dosage has been decreased or discontinued, the lesions disappear, and, in the majority of the cases studied, the preparation could be readministered with no recurrence. We attributed this to the fact that in none of these cases was the dosage returned to the previous high. There is a possibility that a form of desensitization has been produced, but this requires more study for corroboration. Cases in which dermatitides have cleared without interruption of therapy have been described.[5] Although there were purpuric and petechial eruptions in some instances, there was no alteration in the platelet count. In several of the cases we noted that the individuals predisposed to seborrhea had a decided flare of their seborrheic dermatitis. The fact that no mucous membrane lesions have been observed in these cases places this drug in a unique category.

We cannot account for the fact that we have seen no cutaneous reactions in the Negro race, but one could speculate that this is because of either the low case incidence in this series or better tolerance of sunlight. The generalized reactions have been much more frequent in women, but the cases of photosensitization are approximately equal in the two sexes. The contact-type dermatitis was also more prevalent in women, but this is probably occupational. Routine positive patch tests were found equally divided between men and women.

The rather marked number of reactions to the full-strength closed test puts this preparation into the primary irritant category. By the same token, the patch test method is precluded as an indicator of whether a prospective patient might react to this substance. It is thus similar to other drugs that give dermal reactions, in that the patch test is of little value in determining sensitivity. However, we feel that definite epidermal sensitization to this product does develop, as demonstrated by the cases of contact dermatitis. Due to the marked flares of the involved areas when the full-strength patch test was utilized, it is felt that a 10% concentration with the closed patch test or the open drop method should be used when testing for sensitivity. The mild sweat retention syndrome that was demonstrated in a number of cases is attributed to the inflammatory action manifested in the regions of the lower epidermis or upper dermis.

Summary and Conclusions

Eighty-five persons tested had various types of reactions to chlorpromazine. In the majority, patch tests, as well as results obtained from testing several hundred volunteers, revealed that this substance is a primary irritant when applied at full strength. This suggests that patch tests are of little value in determining whether a patient might react to chlorpromazine given systemically. It is suggested that a 10% solution in a closed patch test or full-strength open tests be utilized when attempting to determine contact sensitization reactions. There is probably a critical dosage level that is necessary to produce a reaction in the majority of cases. In this study the range was above 400 mg. of chlorpromazine per day and in most instances was near 600 mg. per day. It is thought that the dosage level plays no role in the production of a photosensitization reaction. Almost all types of cutaneous reactions have been induced by chlorpromazine, with the exception of mucous membrane lesions. The skin reactions following systemic administration of this drug clear r[illegible] the dosage is decreased or discontinued, whereas contact dermatitis is usually severe and recalcitrant to therapy.

PRELIMINARY OBSERVATIONS ON USE OF FRENQUEL IN HOSPITAL PSYCHIATRY

Sidney Cohen, M.D.
and
Richard R. Parlour, M.D., Los Angeles

• *The effects of Frenquel were studied in 100 psychotic patients. Symptoms proved to be more useful than etiology in classifying the results, and many disturbed patients were quieted regardless of the accepted diagnosis. Improvement, if it occurred, was unequivocal and convincing. Twenty-two of the psychotic patients, for instance, were classified as subacutely disturbed, and 13 of these were definitely improved. Among 20 psychotic patients with subacute conditions classified as quiet, however, there was improvement only in six. The highest percentage of successes was among 11 acutely psychotic patients, 8 of whom were definitely improved. Many of the patients received 100 mg. of the drug intravenously in the beginning and continued receiving from 80 to 180 mg. daily in divided doses by mouth, but as a rule the dosage was 40 mg. by mouth four times a day. Six case histories are given to illustrate the uses of Frenquel. It did not manifest specific antihallucinatory properties, did not produce the immobilization that can be obtained with chlorpromazine or reserpine, and did not afford good control of anxiety in the nonpsychotic patient. Its greatest value was in controlling the hyperactive, acutely disturbed patients whose usual emotional defenses are in process of breaking down. In such patients it can be used over longer periods of time, for it proved to be singularly free from side-effects.*

Our interest in Frenquel [α-(4-piperidyl) benzhydrol hydrochloride] was stimulated in part by earlier studies with pipradrol (Meratran) hydrochloride, an antidepressant and antifatigue compound, and in part by the work of Fabing,[1] who reversed, with intravenous administration of Frenquel, the hallucinations and perceptual and emotional distortions produced in normal subjects by lysergic acid diethylamide (LSD-25). The published reports of clinical experiences are incomplete at this time.[2] From impressions derived from the study of 100 cases, however, an attempt has been made to answer five questions: 1. What are the indications for the use of Frenquel? 2. Does it possess a specific antihallucinatory effect? 3. How do the results of Frenquel therapy compare with those of reserpine and chlorpromazine hydrochloride? 4. Is Frenquel synergistic with the other tranquilizing drugs? 5. Are there any side-effects in therapeutic dosage levels?

Indications for Use

The indications for the administration of Frenquel seem to depend not on the clinical diagnosis but rather on the patient's behavioral pattern and the course of the illness. In general, indications for the use of this drug are (1) an acute psychotic reaction and (2) an increase in psychotic manifestations, such as disorientation, confusion, delusions, hallucinations, or hyperactivity. The following conditions are worthwhile indications for a trial of Frenquel: acute schizophrenic reactions or exacerbations of a chronic schizophrenic process, acute manias, and delirious

lous eruptic

mias due to endogenous or exogenous toxins. The table summarizes the results of Frenquel therapy in 100 psychotic patients. In evaluating improvement, it appeared more significant to classify the patient by the terms "quiet" or "disturbed" rather than by etiological diagnosis. Of this group, two-thirds were schizophrenic; patients with manic-depressive psychosis, toxic psychosis, and cerebral arteriosclerosis made up the rest. Disturbed behavior and the acuteness of the illness appeared to be prognostically positive factors. Psychiatric rating scales were not used, because we were interested in more than subtle behavioral changes. Where definite improvement is recorded, either the patient's condition went into a complete remission or the psychotic process was unequivocally improved.

Anxiety in the nonpsychotic patient is not well controlled with Frenquel. Eighteen patients with severe anxiety symptoms due to acute myocardial infarction were given a course of this drug. Two of the 18 developed toxic psychosis complicating their serious cardiac disease. While taking Frenquel, their confusion, disorientation, and panic-like state abated; but, when they were given placebos, their disturbed condition recurred, being brought under control again with the resumption of use of Frenquel. The remaining 16 showed no definite response to the drug. We inferred from this experience that Frenquel cannot be expected to modify anxiety in the nonpsychotic individual. However, it was gratifying to find a drug without hypotensive properties that could be used to reverse the psychotic delirium that is seen sporadically after a myocardial infarction.

TABLE 1.—*Evaluation of Improvement in Patients on Frenquel Therapy*

Condition and Classification	Definite	Slight or Questionable	No Change
Acute	8	3	...
Subacute			
Quiet	6	6	8
Disturbed	13	2	7
Chronic			
Quiet	...	6	24
Disturbed	6	5	6

Antihallucinatory Activity

Since hallucinations and perceptual and emotional distortions produced by lysergic acid diethylamide had been reversed by Frenquel,[2] it was anticipated that Frenquel might have a specific antihallucinatory activity. Our findings do not support this assumption. Although some patients lost their hallucinations, and many became less disturbed by them as their mental disorder ameliorated, there seemed to be no preferential reduction of the hallucinatory segment of their illness. Hallucinatory and delusional perceptions would seem to be projections of psychotic anxiety and are attenuated by a reduction of the anxiety. To test the premise that Frenquel is not solely an antihallucinatory agent, the 30 "quiet" patients with chronic hallucinations reported in the table were selected for treatment. No material subjective changes were observed. On the other hand, the six "disturbed" patients with chronic schizophrenia (see table) who showed definite improvement in their total clinical picture also ceased reacting to their hallucinations.

Comparative Results and Combined Therapy

Twenty-seven patients had been given prior courses of electroconvulsive therapy, reserpine, or chlorpromazine. In general, these were schizophrenic patients who had done poorly under the electroconvulsive treatments or who had improved initially but later become worse. The majority also had had previous treatment with reserpine or chlorpromazine and had shown variable degrees of improvement while receiving these drugs, but they had had exacerbations when the drugs were withdrawn. These patients were given Frenquel in order to compare its effect with those of the other forms of treatment. It was found to be a satisfactory tranquilizing agent, but, just as with other ataraxics, there were treatment failures. Some patients were improved with use of all three drugs; others responded to only one of them. All the tranquilizing agents give satisfactory results in those psychotic patients with a recent onset or intensification of anxiety or hyperactivity. However, even in this prognostically favorable group there are treatment failures. In an attempt to explain this situation, Sarwer-Foner and Ogle[3] point out that, in the patient whose hyperactivity is, in itself, a defense or who equates passivity with femininity, extreme and antitherapeutic anxiety may develop with the administration of the tranquilizing drugs. We have seen this paradoxical response in a few patients with character disorders.

Within the limits of the specific indications, Frenquel seems to be comparable to reserpine and chlorpromazine in ataraxic effect, that is, in its ability to diminish mental confusion. However, it does not possess the immobilizing action of these agents. Under immobilization we include the loss of spontaneity, muscle weakness, and sedation that both reserpine and chlorpromazine can produce. In certain situations it is desirable to immobilize the patient; for example, when he is dangerously disturbed. Some of the best therapeutic results attributed to chlorpromazine and reserpine have been due not to their ataraxic effect but to their ability to immobilize otherwise unmanageable patients. Nevertheless, in some cases, immobility is undesirable and may represent a toxic action of the drug.

A small number of schizophrenic patients who had not improved on therapy with one tranquilizing agent were treated with a Frenquel-reserpine or a Frenquel-chlorpromazine combination. This combined therapy has produced responses that could not be achieved by giving a single drug. Since the precise mechanism of action of these agents is still unknown, it is impossible to explain why treatment with more than one compound should have real advantages. Reserpine may be involved in release of serotonin[4]; and chlorpromazine seems to produce changes in enzymatic activity, especially phosphorylation, in certain areas of the brain.[5] Because Frenquel is sometimes effective when other tranquilizers fail and is ineffective in some instances when the others are helpful, we have assumed that it acts on other neurochemical substrates.

Dosage and Side-Effects

Many of our patients were given 100 mg. of Frenquel intravenously at the institution of treatment and continued receiving orally amounts varying from 80 to 180 mg. daily in divided doses. As a rule, 40 mg. four times a day was ordered. When it was apparent that the drug produced no side-effects whatsoever in these amounts, an attempt was made to determine whether massive doses would improve the therapeutic results. Ten of the patients whose condition had changed only slightly on administration of 160 mg. daily were given 1,200 mg. daily for three weeks. On this regimen they showed no further improvement, but it was impressive to note that no side-effects or measurable disturbances of renal or hepatic function were detected.

An unsuccessful effort was made to uncover complications due to Frenquel therapy in our patients. No hypotensive reactions occurred. Psychotic patients with hypertension showed no drop in blood pressure as they had with reserpine. One patient commented on an unpleasant taste in his mouth while taking Frenquel. With proper indications, Frenquel may be the drug of choice because of its lack of adverse side-effects and its rapid action. Often the patient's response to the first intravenous injection will apprise the physician as to whether the patient will respond to Frenquel therapy. The drug should be withdrawn or another added if, after a few days' treatment, no beneficial effects are observed.

Report of Cases

CASE 1.—A 45-year-old man who had had no previous overt emotional difficulties sustained an acute coronary thrombosis just before admission to the hospital. His mother and father had died suddenly of heart attacks a few years previously, and three months before his illness his wife had deserted him. Shortly after his admission the thrombosis extended, leaving him seriously ill. He had frequent hallucinatory episodes and uncontrollable crying spells. Meperidine (Demerol) hydrochloride, and reserpine, 0.5 mg. daily, did not control his panic-like emotional state. Since the patient's blood pressure readings were at hypotensive levels, the physician did not desire to increase the dosage of reserpine. Immediately after Frenquel therapy was begun, the patient was more cheerful. His weeping became infrequent, and the hallucinations did not recur. Use of all sedatives and narcotics could be discontinued. Thus, where small amounts of reserpine had been ineffective, an excellent result was obtained with Frenquel in this patient with an acute psychotic reaction.

CASE 2.—A 39-year-old patient had been hospitalized for 11 years because of physical and verbal assaultiveness, alternating with periods of complete negativism and mutism. Several courses of electroconvulsive therapy during this time had been without benefit. A lobotomy one year previous to our study quieted the patient somewhat, but he still required almost continuous restraint and was periodically destructive or withdrawn. His auditory hallucinations were especially bothersome to him. While receiving 400 mg. of chlorpromazine daily, he seemed somewhat more relaxed and stopped breaking windows. Frenquel, 80 mg. daily for three weeks, was substituted, with the patient showing marked reduction of hyperactivity and aggressiveness. Then chlorpromazine, 1,600 mg. daily, was given instead of Frenquel; the patient became agitated, requiring frequent neutral packs and restraints. When Frenquel therapy was resumed, the patient quickly showed an excellent response and no longer needed restraints or hydrotherapy. He still occasionally paces the floor and gnashes his teeth, but he claims that he is no longer troubled by hallucinations. He has recently gone on his first furlough from the hospital in 11 years. He has been on maintenance therapy with 80 mg. of Frenquel daily for the past six months without relapsing to his previous destructive behavior. Thus, Frenquel was better than chlorpromazine in handling this difficult patient.

CASE 3.—A 57-year-old patient with hebephrenic schizophrenia, whose illness has extended over the past 20 years, was given reserpine, 6 mg. daily, to control his destructive, assaultive behavior. The therapeutic result was satisfactory. However, when reserpine therapy was discontinued, his hyperactivity recurred. Upon receiving 160 mg. of Frenquel, he showed the same measure of improvement that had been noted with reserpine. In this case, then, Frenquel was as effective as reserpine.

CASE 4.—A 25-year-old patient with paranoid schizophrenia had been hospitalized for 10 months because of assaultive and suicidal behavior, apparently in response to visual and auditory hallucinations. His ward physician summarized his treatment as follows: 160 mg. of Frenquel produced the same tranquilizing action as 16 mg. of reserpine and was more effective than 1,400 mg. of chlorpromazine daily. He stated further that Frenquel had no detectable effect upon the patient's hallucinations.

CASE 5.—A 64-year-old patient had been hospitalized for four years with a condition diagnosed as chronic brain injury due to alcoholism. He was restless, confused, and disturbed. When he was given 2 mg. of reserpine, his behavior was gratifyingly improved. After reserpine therapy was discontinued because it caused excessive drowsiness, the patient gradually relapsed. Frenquel therapy was started, with the result that his behavior again improved and he was no longer "dopey" as he had been while receiving reserpine. On this regimen, the former good result of reserpine therapy was regained and the undesirable side-effect was eliminated. Thus, Frenquel alone was able to control the psychomotor overactivity, and the grogginess that accompanied reserpine therapy could be avoided.

CASE 6.—Although this psychotic patient with cerebral arteriosclerosis was 89 years old, he represented a real problem in management because of his assaultiveness. He would attack attendants and other patients in response to delusions and had to be kept in restraints or oversedated with barbiturates. Chlorpromazine produced syncopal attacks, and reserpine was ineffective in controlling his condition. Therapy with Frenquel in 160-mg. daily doses resulted in a marked decrease in his assaultiveness. Each time the use of Frenquel was discontinued, to determine whether it was actually the effective agent, the nurses would protest to the ward physician. All observers are now agreed that the quieting effect noted while the patient was receiving Frenquel was not fortuitous. Frenquel was the agent of choice in this management problem.

Conclusions

Frenquel [α(4-piperidyl) benzhydrol hydrochloride] is of value in the hyperactive, acutely disturbed psychotic patient whose usual emotional defenses are in the process of breaking down. In the functional psychoses, a specific antihallucinatory property was not demonstrated. Frenquel does have effective ataraxic properties, although it will not produce the immobilization that chlorpromazine or reserpine can accomplish. The effects produced by Frenquel when combined with reserpine and chlorpromazine are encouraging and should be studied further. Since Frenquel is singularly without side-effects, it is the drug of choice when the other ataraxics produce undesirable reactions.

TREATMENT OF LABIAL ADHESIONS IN CHILDREN

O. William Anderson, M.D., Seattle

• *Labial adhesions, in which the opposing epithelial surfaces of the labia minora stick together without any union of the deeper tissues, were observed in a number of young patients over a period of five years. Three cases are cited to show how these adhesions appear and disappear irregularly. At times it is easy to separate them; at other times it is painful. They are likely to recur when separated, but tend to disappear with maturity. When they cause symptoms such as dysuria, they should be separted. If they do not cause symptoms they should not be treated, but they should be brought to the attention of the parents and their generally harmless nature should be explained.*

Anyone who examines a large number of children and includes as part of his routine examination an inspection of the external genitalia will commonly find the labia minora fused together in the midline in the female infant and child. Even though the condition is a common one, there has been relatively little written on the matter. The purpose of this paper is to suggest that these adhesions be treated in a manner different from that recommended in what few articles have been written on the subject. Vulvar synechias, vulvar fusion, gynatresia, and coalescence of the labia minora are other names that have been given to these adhesions. However, since it is only the labia minora that are involved and since there is no true tissue union between the two labia but only a sticking together of the epithelial surfaces, the name labial adhesions seems adequate and will, therefore, be used in this paper.

No doubt many of the older doctors were aware of these adhesions and their nature, but it was not until 1936 that the first report appeared in American literature. This was by Nowlin and Adams,[1] who presented eight cases. A second article, published in 1949 by Nowlin and co-workers,[2] reported that they could find the reports of only 29 cases in American literature. However, they stated that the foreign literature was quite extensive. A clue to the actual frequency of these adhesions can be obtained from an article that was written by Bowles and Childs[3] and appeared in 1943. These latter two doctors tabulated 20 cases seen in their practices in less than one year. It is probable that the experience of these latter two reporters has been similar to that of most pediatricians, who have assumed that everybody else was aware of the frequency of these adhesions and so there was no use in writing about them. Thus it can be seen that, reading the literature, one gets an entirely erroneous concept as to the frequency of the condition. However, if one is not aware of the nature of this condition when first confronted with it, he is apt to make the mistake of believing the child has a serious congenital deformity. There are, in the few articles written, a number of instances cited in which this interpretation of the nature of these adhesions has caused unnecessary alarm on the part of the parents of the child.

Acquiring of Adhesions

In the earliest reports on this condition, it was assumed that the adhesions were congenital because they were present when the child was first examined, and the assumption was made that they had always been there. Thus, in 1940, Campbell[4] postulated an embryologic explanation that there was a midline fusion of the labioscrotal folds similar to the fusion that develops in the male but lacking the density of scrotal fusion. However, the large number of routine physical examinations that have been done on children in recent years have revealed adhesions in patients free from them in previous examinations, thus proving that the adhesions were actually acquired. Bowles and Childs,[3] in their report on 20 cases, stated that in one patient the fusion was definitely present at birth but that in all of their other patients it was noticed first in later infancy. Since the majority had had previous examinations, they were thus known to have acquired the condition. The one case observed at birth is unique, so far as I know. Its uniqueness is better realized when one considers that, as shall be seen later, these adhesions tend to disappear as the genitalia attain their adult characteristics. Then, when one remembers that the female newborn infant's genitalia temporarily have many characteristics of the adult's due to a leakage of some of the mother's female hormones into the baby's circulation, it can be understood why these adhesions are seldom seen in the newborn infant.

When it was realized that the adhesions were acquired, then, naturally, came the question as to why these children acquired them. The most commonly stated explanation for the appearance of the adhesions has been that they follow an inflammatory process in the vulva, at which time the edges of the labia are denuded and are then able to adhere one to the other. This has not been a satisfactory explanation of the cause. Many children who are more or less poorly cared for have some irritation of the vulva but no adhesions. On the other hand, children who are well cared for and are at all times free of any inflammation in this area commonly have adhesions. My experience has been that certain children tend to form adhesions for no apparent reason. By this I mean that the girls in whom these adhesions are present are, as a group, no different in their anatomy or in any other way from any other group of girls, insofar as I have been able to discern. Also, it has been observed that, when the adhesions are separated, they will often recur; and they recur repeatedly unless the mother is instructed to make almost a daily inspection to keep them separated. A possible explanation for the presence and recurrence of these adhesions is that the mucus secretions in such girls contain a certain peculiar musilaginous property that causes these two opposing surfaces to adhere, while, in girls with a more fluid type of mucus secretion, there is no tendency for adhesions to develop.

Lack of Symptoms

There are ordinarily no symptoms resulting from the presence of these adhesions. Other writers have noted this also. However, there is an occasional case of a child who does have some trouble. I have seen four cases in which a child was complaining of mild dysuria, which was, in each case, relieved by separating labial adhesions. Some writers have suggested that the adhesions might lead to urinary tract infection and be conducive to masturbation, but there are no well-documented instances in which this has been true. Barysh[5] mentions a patient who had enuresis in whom he found these adhesions; though there was no recurrence of the adhesions after he separated them, the enuresis persisted. Thus it would seem logical to assume that the adhesions were not the cause of the enuresis.

If it is agreed that the adhesions cause little trouble in the child, another question is: How does their presence affect the adult female? The answer is that, with maturity, the adhesions dissolve and disappear spontaneously. One must draw this conclusion, because, whereas the condition is known to be common in children, it is questionable that it is ever found in the adult. Campbell[6] reports having found firm adhesions with a tiny labial orifice in a 69-year-old female, and Taylor,[6A] in 1941, reported a case in a woman 74 years of age. If these were first observed at this age, one would wonder if they had not been acquired in later life in a manner similar to that in which the infant or small child acquires her adhesions. This would seem logical when one remembers that, in the elderly female, the genitalia atrophy and undergo changes so that they come to resemble the child's genitalia.[7] The fact is that adhesions in normal young and middle-aged adult women have not been reported.

Campbell[4] says that urinary disturbances could occur in children with marked labial fusion, and, as puberty is reached, the menstrual flow could be retained by the minute orifice, causing its collection in the vagina. However, none of his patients had menstruated, and he does not document any cases in which there were any of these complaints. In a similar vein, Bowles and Childs,[3] in their article on the subject, maintain that failure to eliminate labial synechias may occasionally be the cause of serious urinary and menstrual dysfunction or may prevent normal sex life. They do not, however, document any cases in which this has been true.

Treatment

In regard to treatment, all of the authors reviewed gave more or less the same advice, namely, that the adhesions be separated at the time they are discovered, regardless of whether or not the patient is having any symptoms due to the adhesions. It is recommended that an anesthetic be used, if necessary, while the adhesions are being separated. Then it is recommended that the raw labial edges be kept separated for some days while they are healing. This can be done with bland ointment or petrolatum or a pledget of cotton kept inserted between the labia until healing has been completed. Mothers are further advised to make frequent inspections thereafter and for an indefinite period of time to prevent recurrent adhesions. Since this latter instruction is commonly given, it is apparent that others have had experience similar to mine, namely, that adhesions tend to recur in certain children.

Prior to five years ago, it was my practice to separate the labial adhesions assiduously, as is common practice with most other practitioners. It was observed that the adhesions were reappearing, and separation was repeatedly being done on the same children.

There can be no question that separating of the adhesions is painful to the child, the degree of the pain depending somewhat on how firm the adhesions are. After separating the adhesions, one will observe that there is a red raw line on the edge of each labium where the adhesion has been broken. These raw edges, however, do not bleed. It was my practice to instruct the mother to put petrolatum on these edges until they had healed, but it was never my practice to instruct the mother to make a daily inspection of the child's genitalia for an indefinite period of time. Too-frequent attention to the child's genitalia is not advantageous, from a psychological point of view, if for no other reason. On several occasions the mother reported that the child had painful urination for 24 hours after the separation of these adhesions. This is easy to understand, since the passage of urine over the raw surface created by the operation no doubt would be painful. If the mother reported at the time the child was having trouble, she was advised to have the child urinate in a warm bath and thus gain relief.

For approximately the past five years, it has been my practice, whenever adhesions have been found on routine examination, to leave them entirely alone. However, at the time they are observed, they are pointed out to the mother and their presence described to her. At the same time she is told that this finding is purely incidental, that the adhesions are obviously causing no trouble, and that with maturity, or perhaps sooner, they will disappear. She is also told that it has been my experience that they seldom cause trouble and that if they are separated, they will probably recur. She is reassured that, if they do cause trouble, the trouble will probably be discomfort with urination and that the discomfort can easily be cured by separating the adhesions at the time the child is having the trouble. This treatment plan, which might be called the "no treatment plan," has been entirely satisfactory, and in every case the above explanation, when given, has been satisfactory to the mother also.

Report of Cases

CASE 1.—On routine examination of a girl who was first seen when she was 8 years old, firm labial adhesions were found. When their presence was pointed out to the mother, she stated that they had been present at every examination that the child had had since infancy and that at each examination the pediatrician had separated the adhesions. When an effort was made to separate the adhesions in the usual manner, it was soon apparent that the child was going to give a considerable amount of resistance and would certainly require an anesthetic. Since the adhesions were causing the child no trouble, it was agreed that they would simply be watched. One year later, when the child was 9 years old, the adhesions had partially disappeared and there was a good-sized opening between the anterior half of the labia. Again, when the child was 10 years of age, the adhesions were complete and firm. Two months after this examination, the child came in with the symptoms of frequency of urination and dysuria of two days' duration. The urine was clear, but she had firm, complete adhesions. The child permitted their separation without anesthesia, and there was immediate relief of symptoms. One year later, when the child was 11, the adhesions were again present and the child permitted their separation. Since this last examination the child has been followed by an internist, and there has been no further recurrence of the adhesions.

Case 2.—A child was seen at birth, at one month, and at 2 months, with no adhesions. At the 4-month and 6-month examinations, adhesions were present and were broken. At 9 months, there were no adhesions present. At one year, adhesions were present and were broken. At one and one-half years, adhesions were present and broken. There is no note on this subject from the 2-year examination. At the 3½-year and 4½-year examinations, adhesions were present and were left unbroken. At the 6-year examination, very firm adhesions were present with no opening seen, but they were left unbroken. At the 7-year examination, no adhesions were present. From age 2 on, each annual examination included a urine examination, which was always negative.

Case 3.—The younger sister of the patient in case 2 was seen at birth, one month, and 2 months with no adhesions present. At the 4-month examination, adhesions were present and were left unbroken. There is no note on this subject from the 6-month, 9-month, and one-year examinations. At the 18-month examination, adhesions were present and were left unbroken. At the 2-year, 3-year, and 4-year examinations, adhesions were present and left unbroken. At the 5-year and 6-year examinations, no adhesions were present. From 2 years of age on the child had yearly urine examinations, all of which were negative.

Conclusions

Labial adhesions are common in certain children, possibly due to some peculiar tenaciousness of the mucus secretions on the surfaces of the labia. Every doctor should recognize these adhesions in order to avoid causing alarm to parents. These adhesions seldom cause any trouble, but, if symptoms should develop that can be blamed on the presence of the adhesions, the labia should be separated at that time. Since these adhesions do cause little trouble and their removal is painful, and since they tend to recur and do tend to disappear with maturity, in most cases a "no treatment plan" should be tried.

GRANULOMAS OF THE AXILLAS CAUSED BY DEODORANTS

Louis Rubin, M.D., Rockford, Ill., Albert H. Slepyan, M.D., Highland Park, Ill., Leonard F. Weber, M.D.
and
Irene Neuhauser, M.D., Chicago

• *A new clinical entity, in the form of a previously unseen skin eruption, appears to be developing from the use of certain deodorant and antiperspirant preparations. While the clinical appearance and pathological examinations are consistent in all patients observed to this time, the exact etiology of the granulomatous lesion is still to be determined. This chronic condition, while evidently resistant to treatment, in the acute stage may be somewhat alleviated by topically administered steroids.*

A few months ago we submitted to The Journal a preliminary report on four cases of unusual eruption in the axillas after use of certain deodorants.[1] Since these cases are occurring more frequently, we are prompted to submit a more detailed clinical report so these cases may be more easily recognized. The original cases were all quite characteristically alike clinically and on histopathological examination and different from previously described eruptions in the axillas. All followed the use of a deodorant for a period of a few days to several months.

Report of Cases

Case 1.—A 37-year-old female office worker in December, 1955, developed an eruption in both axillas consisting of dusky reddish-brown papules that measured 1 to 4 mm. in diameter. These were very closely set in the domes of the axillas, but were more discrete at the periphery. Some of the lesions resembled vesicles, but yielded no fluid when punctured. Itching was mild. During the following six months the lesions flattened slowly, but considerable hyperpigmentation remained. Daily applications of stick deodorant had been used for two weeks prior to appearance of the eruption.

Histological sections, stained with hematoxylin and eosin, were prepared from a biopsy specimen of a typical papule in the left axilla. Upon first examination with the low-power lens, dense granulomatous infiltrate was seen, involving practically the entire corium. The infiltrate consisted of numerous epithelioid cells and giant cells closely packed together to form a tuberculoid pattern (fig. 1). Lymphocytes were present, but were not as numerous as expected. Most of the giant cells resembled the Langhans' type, as seen in tuberculosis, but some had the appearance of foreign body giant cells. There was no sharp circumscription of the tubercles that is so characteristic of sarcoidosis or sarcoid reaction. Necrosis was absent. The epidermis had lost its rete-peg structure and appeared thin, probably due to the pressure of the infiltrate from below. Polaroscopic examination of the same sections did not reveal foreign bodies.

Case 2.—A 30-year-old housewife suddenly developed a papular eruption in each axilla in January, 1956. For one month previously she had used daily applications of a stick deodorant.

From the Department of Dermatology, University of Illinois College of Medicine, Chicago.

When first seen three months after onset of the eruption, she had numerous flesh-colored, smooth-surfaced, semiglobular, semitranslucent, discrete papules 1 to 4 mm. in diameter, which at first glance resembled vesicles. A few of the lesions were arranged in lines. Itching was minimal. Previous treatment with superficial x-ray therapy and hydrocortisone ointment had improved the condition only slightly.

Examination of histological sections stained with hematoxylin and eosin, from a biopsy specimen of a papule in the axilla, revealed a tuberculoid granuloma in the corium. The granuloma consisted of epithelioid cells and Langhans' giant cells surrounded by lymphocytes, to form the characteristic tuberculoid pattern (fig. 2). Necrosis was not discernible, and numerous small blood vessels were included in the granulomatous mass. Again the sharp delineation of tubercles necessary for a diagnosis of sarcoidosis was absent. The infiltrate followed along the course of vessels downward into the corium. Polaroscopic examination for foreign bodies was negative.

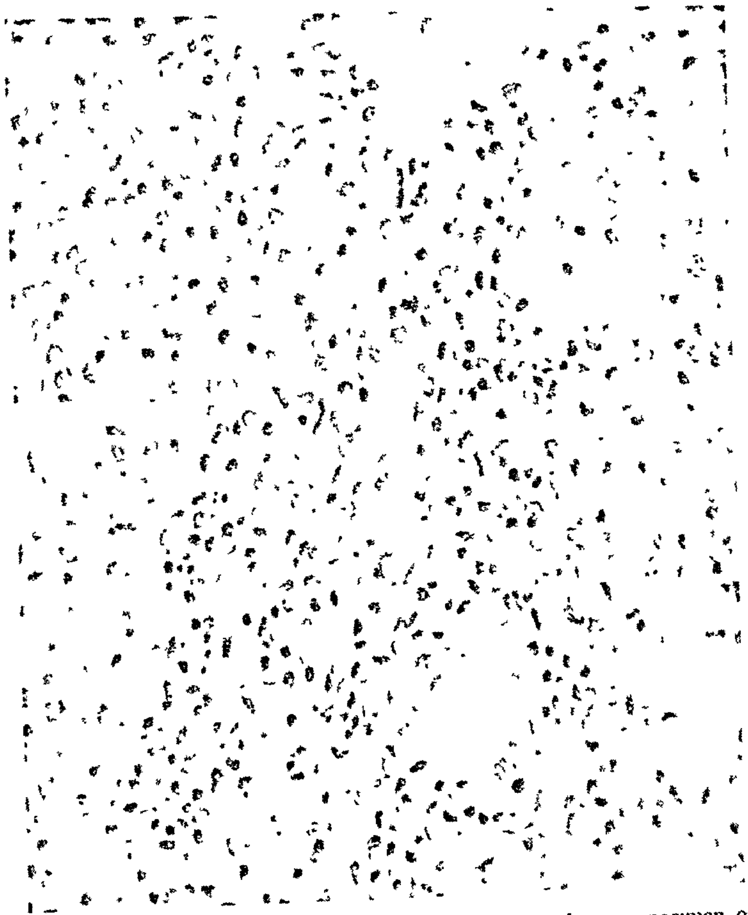

Fig. 1.—Photomicrograph of section prepared from biopsy specimen of typical papule in left axilla of patient in case 1.

Case 3.—A 56-year-old female stated she applied a stick deodorant to each axilla on March 17, 1956. The following morning the axillas were shaved. Two days later a moderately pruritic eruption appeared. When she was first examined five weeks later, there were innumerable dull, brownish-red pinhead-to-matchhead-sized papules in both axillas (fig. 3). Many of the papules were shiny and somewhat translucent. Pricking of the lesions did not reveal fluid. On diascopic pressure, "apple jelly" color was noted. After five weekly treatments with superficial x-ray therapy and application of hydrocortisone in lotion and cream form, there was little change except for a somewhat more yellow color and slight scaling. Intradermally given purified protein derivative of tuberculin, first strength, gave a negative reaction; the second strength showed a faint split-pea-sized reddish papule.

Sections stained with hematoxylin and eosin showed the essential pathology in the upper corium. A fairly dense granulomatous mass consisting of epithelioid cells, Langhans' giant cells, lymphocytes, and an occasional eosinophil surrounded a hair follicle (fig. 4). Many small blood vessels were included within the granulomatous area. Again polaroscopic examination did not reveal foreign material.

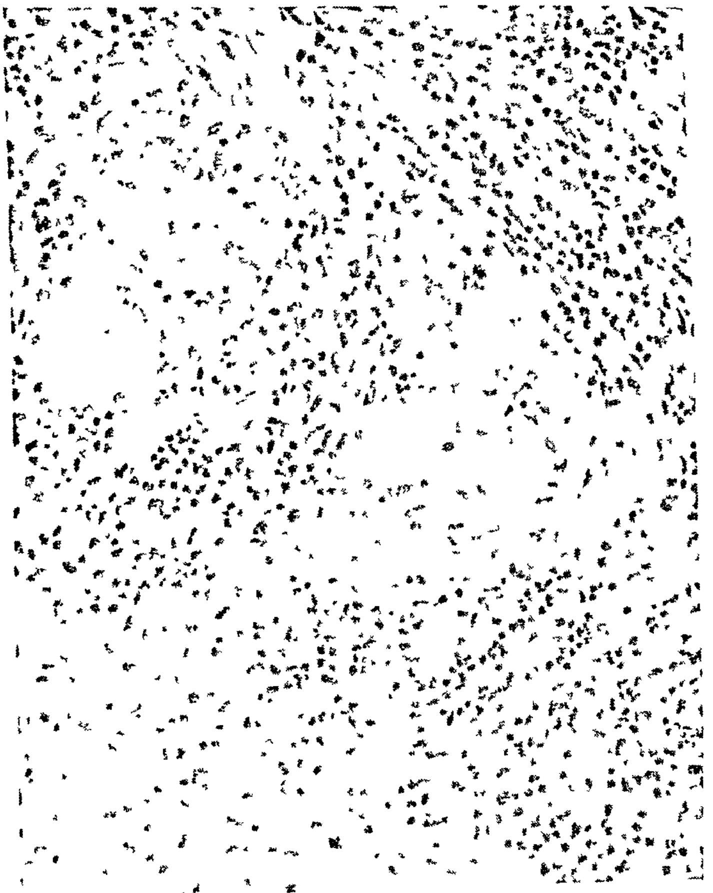

Fig. 2.—Photomicrograph of section prepared from biopsy specimen of papule in axilla of patient in case 2.

Case 4.—A 31-year-old female schoolteacher stated that two days after applying a deodorant lotion she noted burning and itching of the axillas. She had applied the lotion in the morning and had shaved the axillas that night. When examined 10 days later, both axillas were studded with BB-sized (about 2 mm. in diameter), dull, reddish-brown discrete papules. The lesions appeared glossy, with an occasional overlying telangiectatic vessel. Microscpoic examination of a typical papule revealed the tuberculoid structure seen in the other patients.

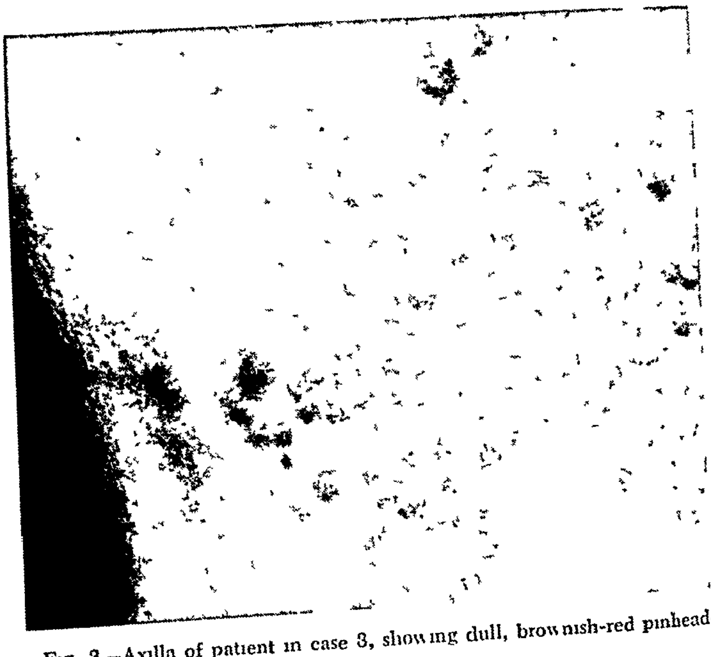

Fig. 3.—Axilla of patient in case 3, showing dull, brownish-red pinhead-to-matchhead-sized papules.

Comment

In each of the four cases the histological sections showed a similarly striking microscopic pattern. The composition of the deodorant stick used by the patient in case 2 is as follows: glycerin, 3% by weight; Carbitol, 3; dichlorophene, 0.375; hexachlorophene, 0.375; alcohol (SDA no. 40), 50; water, 9.45; sodium stearate, 8.5; propylene glycol monostearate, 2; cetyl alcohol, 1; sodium zirconium lactate solution, 22; and perfume, 0.3. The stick deodorants used by the patients in cases 1 and 3 were also "gel"-type sticks containing sodium zirconium lactate. The granuloma in case 4 was caused by a lotion-type deodorant that contains chlorhydroxyaluminum sulfate, but no zirconium.

Fig. 4.—Photomicrograph of section prepared from biopsy specimen of papule of patient in case 3.

An attempt to demonstrate the presence of zirconium in a biopsy specimen from the patient in case 3 was reported by A. E. Osterberg, Ph.D., of Abbott Laboratories, as follows: "This sample, which when desiccated weighed only 0.563 mgm., did not show any zirconium by spectrographic analysis. This means that there is less than 0.3 mcg. of zirconium present. Since the sensitivity of spectrographic analysis is of the order of 0.3 mcg. of zirconium, it is suggested that a biopsy specimen of 10 mgm. would increase the sensitivity and give a more positive determination."

Patients seen by us subsequently, and some reported to us by other dermatologists, have in some instances shown more diffuse erythema and more severe pruritus of irritant reaction in addition to the tuberculoid-type reaction. Other patients have shown evidence of overtreatment dermatitis, and the characteristic papular eruption became evident only after the acute process had subsided. In all cases the condition has been chronic and resistant to therapy, apparently does not respond to x-ray therapy, and is only ameliorated by use of topically administered steroids.

As yet we have no proof of the cause of the unusual reaction observed, but we are investigating the role of sodium zirconium lactate, the entire deodorant preparation, and its individual components. The role of abrasion is also being investigated, because of the appearance of some lesions in lines, suggesting occurrence in razor abrasions. The deodorant preparations used by several of the patients suggest in their advertising that they may be used immediately after shaving the axilla.

Summary and Conclusions

In four cases of a new and unusual type of eruption in the axillas due to deodorant and antiperspirant preparations, the clinical appearance was characteristic and the histopathological pattern revealed a characteristic granuloma suggesting a tuberculoid reaction. Since the original patients were observed, 11 others have been seen by members of our group. It appears that these cases are becoming more frequent. Therefore, further study is indicated to trace the offending mechanism.

Cancer Concept.—The specious statements that "nothing is known about cancer" and "no man knows the cause of cancer" are commonly made, thoughtlessly no doubt, by medical men who should know better. Thousands of articles in journals and books in medical libraries bear witness against them, as does the unceasing work of the many competent investigators in well-equipped laboratories, who daily produce cancers at will. A great deal is known about hundreds of cancers, and known causes run into hundreds as well. Moreover, doctors daily diagnose, treat and cure indubitable cancers as they do other diseases. . . . The cancer concept depends on a sharp change in behavior observed in body cells themselves. It is a change in which, relative to the rest of the body, they themselves play the part of an invading agent almost as foreign as that of a different form of life such as a bacterium or a virus, and that in a medium not altered otherwise than by the consequences of the change itself. These altered cells no longer conform internally or in external relationships to the regular pattern that characterized their predecessors, but now breed true in a persistent divergence from that pattern. . . . The cancer cell still wears the insignia of a body cell, but its proliferation no longer keeps the old line or subserves the needs of host-tissue maintenance. The new tissue develops a local imitative, inconstant pattern of its own, acts as an intruder and disturbs the general metabolic balance of the body. The change belongs to the cell and persists whether the inducing agent is discernible or not. Disappearance of the agent does not result in restoration of the status quo.—Sir Peter MacCallum, The Place of Surgery in the Treatment of Cancer, *The Medical Journal of Australia*, March 3, 1956.

tant treatment. These persons are to be made as comfortable as possible. They are given adequate doses of morphine, if available, and placed in the lowest priority group for evacuation and definitive treatment. They do not receive therapy until all patients are cared for in the higher priority groups.

The major effort of available medical personnel should be directed toward administering therapy to casualties having from 15% to 40% involvement. If the entire 40% are deep burns, such persons should be placed in the expectant group. Some casualties with 20% superficial burns might be discharged to self-care.

Percentages are not necessarily hard and fast areas of delineation. Each patient should be evaluated according to the depth of his burn, the area of involvement, and his ambulatory state. Since most of the burns are expected to be flash burns, a large number of partial-thickness burns will occur. If the burning insult occurs following secondary fires, however, the depth and extent of injury might be increased.

Casualties having burns involving less than 15% of the body surface should be discharged to self-care if the location of their injury does not interfere with ambulation. Although many individuals having burns that involve 15% of the body surface are hospitalized today, experience has proved that most of these patients can take care of themselves if they can be supplied with water, food, electrolytes, and antibiotics. In a disaster situation, however, self-care will not be feasible if a casualty has a severe burn of the face, if edema interferes with sight, or if a deep burn of the leg makes ambulation impossible. Casualties who have partial-thickness involvement of 15% of the trunk might care for themselves. Many individuals with minor burns might be utilized to help care for the more seriously injured.

In the event of thousands of casualties, it is expected that most of those who survive will be those with burns of such configuration that they can care for themselves. Many casualties who have slight full-thickness involvement might be expected to care for themselves initially and then receive treatment later in a hospital where grafting can be performed. Casualties who have minor second-degree burns might be expected to care for themselves; at the same time they might either assist in the care of other individuals or resume their regular tasks.

It is expected that most of the sorting will be carried out by the casualties themselves. It is hoped that those who can continue to carry on some type of work might make themselves useful and not overburden the medical facilities.

Supportive Therapy

The main type of initial, supportive therapy is supplying water and electrolytes. Normally the patient's loss of sodium and fluids is replaced by intravenous administration of lactated Ringer's solution. In time of disaster, such replacement therapy will have to be carried out by means of orally given electrolytes. A solution of salt and soda made by placing 3 gm. of salt and 1.5 gm. of sodium bicarbonate into 1 liter of water is an effective solution for replacement therapy. Should the number of casualties be relatively small, with an adequate number of trained medical personnel available, then fluid therapy might be given intravenously. It is doubtful whether the subcutaneous route would be of much value, because fluid and electrolytes are not absorbed rapidly in a burned individual.

In order to provide a replacement solution, it might be possible to have salt, soda, and some type of water-purification tablet placed in small packages to be given to burned patients for mixing with water. The salt-soda solution is well tolerated by burned patients. It provides good replacement of electrolytes for the first 48 hours when the burns are not extensive. Any burned casualty who is to be treated, such as those sustaining an injury of less than 40% of the body surface, could probably receive adequate replacement therapy by the oral route. Burns with deep involvement will require later colloid and blood therapy. In most instances, this supportive therapy will not be available within the first few days. There is ample evidence to show that, unless a burn is very deep, burns involving less than 40% of the body surface can be treated initially without whole blood. The anemia that usually follows such an injury should be corrected later.

Although burn therapy for moderate-sized wounds may be undertaken in a hospital without giving antibiotics, it would be desirable to use antibiotics in casualties discharged to self-care. The main reason for such prophylactic therapy is to prevent severe infections caused by beta hemolytic Streptococcus (Lancefield group A). Since this organism is sensitive to most antibiotics, any broad-spectrum antibiotic given orally should be sufficient for the first few days after injury. At the time a casualty receives the salt-soda solution, he might be provided with a sufficient amount of a broad-spectrum antibiotic to last him for several days.

Since tetanus is a potential threat in burned patients, it is advisable to give antitetanus therapy as soon as it can be obtained. Almost without exception, all military personnel are immunized against tetanus; hence, a single injection of tetanus toxoid is all that will be necessary for this group. In the event of large numbers of unimmunized casualties, antitoxin should be administered if available. However, it will be exceedingly difficult to undertake such therapy because of the tremendous amounts of serum needed and the large number of trained personnel necessary to administer this antitoxin.

It will be almost impossible to provide food of high-protein content for a vast number of burned patients. Therefore, it might be possible to provide some type of powder having high-protein content that can be taken with water as a dietary supplement.

Wound Care

Although the present belief is that most burns have less chance of becoming infected when they are cleansed, such a procedure will be impossible in a disaster situation. There is ample evidence that the lack of cleansing is a minor compromise, especially when burns are exposed. In the event of a disaster, almost all burned areas will have to be treated by the exposure method because few dressings, if any, will be available. Should the disaster occur in a cold region, it will be necessary to furnish blankets or some type of covering for the casualties. If time permits and dressings are available, they should be utilized on individuals who would benefit most from their use. It might be wise to prepare some type of mittens for use on burned hands. If flash burns occur on the hands and face, a burned casualty discharged to self-care can be more effective as a soldier or an assistant if he has something to cover his hands and if he can see.

There has been considerable thought and a great deal of discussion concerning the use of a bland ointment for painful second-degree burns. However, most second-degree burns weep; and, as soon as the initial layer of plasma dries, they are no longer painful. In special instances, such as in the case of a combat soldier, it might be wise to give him some type of bland ointment to cover the burned surface. This would offer him some immediate relief. Psychologically, at least, this would make him feel that his burn had been treated, and he would be able to return to duty as an effective combat soldier. The type of ointment to be used in such situations is now under study. When a selection is made, it is believed that the individual soldier can be issued a small tube of ointment that can be inserted into his first-aid packet.

Burn Centers

Some thought has been given to the initial management of burns in time of disaster. Little discussion has resulted on what might happen to vast numbers of casualties after the first few days. In a military disaster, if the tactical situation allows, the burned soldiers may be moved to a particular area designated as a burn center. If this center is located several miles from the disaster zone at a specified fixed installation, all burn casualties will be cared for in this vicinity. On the other hand, if burned casualties have to remain within the area where they are injured, it might be possible to collect them in a certain region or in a large building. Later care should be given in an installation especially designated for burn therapy. Still another phase of sorting or triage, as this procedure is termed by military physicians, might be necessary in the so-called burn center. Casualties who are able to return to duty after one grafting procedure should be taken to the operating room first.

The difficulty in dealing with thousands of burned casualties is to find space in an operating room and time to carry out the multiple grafting procedures that are necessary. Once the casualties who are able to return to duty after one grafting procedure are treated, the remainder can receive grafting operations according to their needs. In many instances, casualties may need coverage of large, open burned surfaces before space in an operating room is available. The loss of protein and electrolytes through large granulating surfaces might be prevented by means of cadaver homografts. These homografts might be laid on the wound when a dressing is changed. This procedure serves as a biological dressing until space is available in the operating room for autografting. It is ideal for those patients who are to be grafted with their own skin to have complete coverage at the time of initial surgical intervention. If there is insufficient time or if conditions are not such that the wounds can be covered completely at the first grafting procedure, then the autografts should be put on and the remainder of the open granulating areas should be covered with homografts. In this manner, each patient will have complete coverage after the initial grafting procedure. This is necessary because a considerable period of time might elapse before space in the operating room is available for a second grafting.

One of the great needs in a burn center is the provision of blood and some type of high-protein therapy. Large quantities of protein are lost after a burn injury, and skin grafting will take well only as long as a patient does not become completely depleted of his protein reserves. A patient may remain in negative nitrogen balance for a prolonged period; but if he does not deplete his reserves then autografts and even homografts will take. It is a real problem to prevent protein depletion. It is doubtful that adequate protein diets can be served if thousands of casualties are involved. Protein-replacement therapy will have to be carried out by a palatable protein supplement that can be given several times a day.

In grafting procedures, it is desirable for large sheets of skin to be placed over flat surfaces. If surgeons skilled in burn therapy are not available in the event of a vast number of casualties, it will be necessary to compromise on the grafting procedure. Any surgeon can take skin from a person if electric dermatomes are available. If the problem involves large granulating surfaces, the autografts should be cut to postage-stamp size, instead of being applied in large sheets, as these grafts can cover a much larger surface. The cosmetic effect, however, is far superior if sheets of skin can be used.

Summary

In the event of a mass casualty situation involving the use of nuclear weapons, it is obvious that major compromises in burn therapy will be necessary. These compromises will be mandatory in all phases of burn therapy, from early resuscitation to late grafting procedures. In the early phase, therapy to be considered includes (1) oral electrolyte therapy, (2) use of the exposure method except when an individual might be rendered effective by the use of dressings, (3) omission of local wound care involving an operating room, (4) orally given antibiotics, (5) self-care or "buddy system" treatment for all burns involving less than 15% of the body surface except in critical areas such as the face and feet, (6) concentration of care for casualties having burns involving 15 to 40% of the body surface, and (7) low priority for evacuation and treatment for all persons with more than 40% of their body surface involved, providing most of the burn is a full-thickness burn. In the later phases, therapy to be considered includes (1) cadaver-homograft skin applied as a ward procedure, (2) autografts applied in postage-stamp size rather than in sheets, (3) protein supplements by oral ingestion, (4) first priority for grafting of patients with small areas of burns because of early discharge from the burn center, and (5) delay in grafting procedures on many casualties beyond the optimal per
In time of disaster, it will be impossible to exc
full-thickness burns or initiate routine rehabil

IMPACT OF NUCLEAR WEAPONS ON MILITARY AND CIVILIAN MEDICAL ORGANIZATIONS

Brig. Gen. Major S. White (MC), U. S. A. F.

• *Successful offensive tactics in nuclear warfare depend on the development of small, mobile, self-sufficient tactical elements capable of rapid dispersion and regroupment. Successful defense similarly depends on the development of units that will not offer an easy target for a nuclear weapon; they must be flexible and mobile, yet linked by centralized control. The medical support, in particular, must include casualty-treatment units widely dispersed in each community and capable of operating for short periods with communications destroyed. All individuals therein must be trained in first aid for assistance to both themselves and others; organic medical support attached to tactical units must be as small as possible; all other supporting medical units must be mobile, widely dispersed, and centrally controlled; rapid transportation must be available. Individuals concerned with medical care must be available for transfer to and from distant areas, and they must be under some type of disciplinary control, the nature of which, whether civilian or military, should be decided before the emergency arises. Experience gained from a joint Army and Air Force maneuver in 1955 demonstrated these points, but the pattern can also be adaped by civilian communities to the problem of supplying medical care under disaster conditions.*

National defense today is based upon preparation for both general and local wars. In either type, nuclear weapons will play a predominant part. These weapons will be highly selective in their action. They may be used tactically in the local or "limited" war to pinpoint relatively small military targets, or they may be used strategically in a general or "all-out" war to destroy large industrial centers. The three defense forces of the United States—the Army, Navy, and Air Force—are redesigning their combat and support units, which include medical organizations, to meet the requirements imposed by this type of warfare.

Combat units have always striven to obtain the maximum of mobility, in order to gain the initiative, to achieve surprise, and to concentrate fire power. Extreme flexibility must also be obtained. To do this, tactical elements must be small, mobile, self-sufficient, and capable of rapid dispersion and regroupment. One of the main objectives of this type of organization is to present as small a target as possible for a nuclear weapon. Medical support for these new combat needs can be readily met by the inherent flexibility of most of the nation's military medical units. However, area and centralized control are the factors that must be added to permit support on a local or regional basis.

"Exercise Sage Brush" Tests

The organization of military medical support for atomic warfare is illustrated by examples from the joint Army-Air Force maneuver "Exercise Sage Brush" held in the fall of 1955. During this period, 140,000 soldiers and airmen from units throughout the United States participated in the largest joint maneuver held since World War II. The primary purposes of the exercise were to train units for modern combat and to test new techniques and weapons. Therefore, simulated atomic weapons and numerous means for their delivery were made available to the commanders of both the defending United States forces and the invading aggressor forces.

In a nuclear war, as this exercise was, it is axiomatic that for both survival and victory the first order of the day is to obtain air supremacy. This is gained by destruction of the opponent's air power through an air war. Once air supremacy is achieved, freedom of movement is assured for one's own ground and air forces, with denial of this freedom to one's opponent. Air forces can then support ground troops in the exploitation phase of war or in the elimination of any enemy ground troops that might remain. In Exercise Sage Brush, the hope for initial survival of all forces was based on the wide dispersion of tactical units. As can be seen in figure 1. dispersion caused the distances over which the maneuvers took place to be extensive. Air bases of the opposing air forces involved in the air war are shown spread throughout 13 states of the southeastern United States. The shaded portion of the map indicates the ground area in Louisiana over which the field armies maneuvered.

Air Force and Army Organization

In the air forces, the dispersion shown ensured that a wing of 75 aircraft would not be based entirely on one airfield. To have done so would have made possible the destruction of the wing's three squadrons through the successful delivery of one atomic bomb. Therefore, all of the wings were divided, with one squadron or less assigned to any single air base. The problem of supply to these dispersed units was met by the use of air transport. This air transport was. in turn, available for the evacuation of medical casualties and governed the organization of air force medical support that was provided in two ways: one, through the organic medical personnel and equipment assigned to a squadron; the other, through an area support unit covering the entire theater. The squadron medical unit consisted of

---

Surgeon, Headquarters Tactical Air Command, Langley Air Force Base, Va.

Read before the Section on Military Medicine at the 105th Annual Meeting of the American Medical Association, Chicago, June 14, 1956.

a flight surgeon and three enlisted aeromedical technicians. This team was equipped with a compact air-transportable dispensary. It provided for early treatment and for the aviation and preventive medicine care that was considered the minimum essential in the squadron and relied on evacuation to theater units for further medical support. Theater area support was organized into a tactical aeromedical wing under the centralized control of the Air Force commander. This wing consisted of units varying from small 36-bed air-transportable infirmaries to 150-bed fly-away hospitals. It also included an aeromedical evacuation group and other elements for dental, veterinary, laboratory, and preventive medicine services as well as for medical supply. All hospitals had their personnel organized into several disaster teams, consisting of physicians, nurses, and auxiliary helpers. These teams, with emergency supplies, could be detached and sent to the assistance of areas incurring large numbers of casualties.

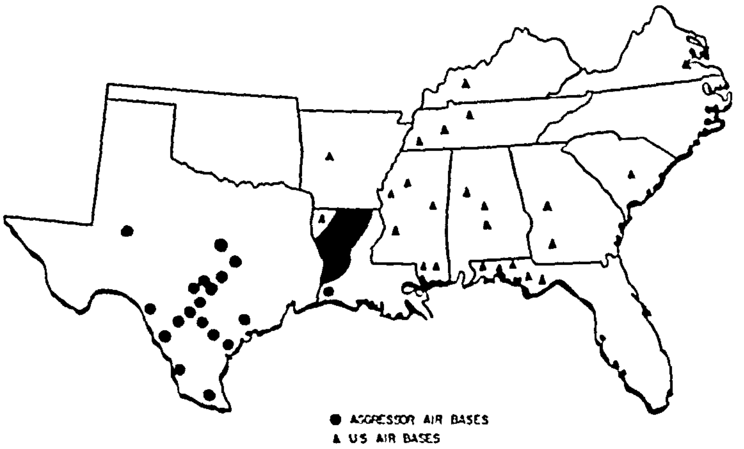

Fig. 1.—Extent of maneuver area in Exercise Sage Brush, showing Air Force units in 13 southeastern states and Army troops in shaded area in Louisiana.

Through centralized control, flexibility of assignment was possible. Hospitals and other units were based in areas where the greatest work load was expected or were moved rapidly in whole or in part as the tactical situation dictated. Need for such control will be even more acute as greater dispersion becomes possible in the future, with combat aircraft developing vertical take-off and landing capabilities. Then squadrons will be dispersed in elements of one or several planes. The contined adaptability of medical support for such a situation was demonstrated in Exercise Sage Brush, when squadrons were dispersed in small elements through the assignment of an aeromedical technician with each element and flying visits by the squadron flight surgeon.

Army forces, similar to the air forces, also had their units organized into the smallest possible tactical elements for self-sufficiency and dispersal. In the forward battle zone, or division area, the medical elements organic to the division were used for early emergency care. Direct support of these units and area medical support in the rear were provided by 300-bed to 400-bed field hospitals. These functioned as one complete unit or were partitioned into independent elements of 100 beds each. In addition, evacuation hospitals, medical supply depots, and clearing and ambulance companies provided support under the control of a centrally located medical group headquarters. Aircraft also were used, as in the Air Force, to supply isolated units and evacuate transportable casualties. For both ground and Air Force troops, supplemental medical supply units were available for delivery to organizations suffering large numbers of casualties. The supplemental supplies were designed around a basic unit of drugs and dressings needed to care for 100 casualties of the type expected in nuclear warfare. Multiples of this basic unit were delivered as required, depending on the number of wounded reported.

The experiences of Exercise Sage Brush demonstrated that, with a rapidly changing tactical situation and the occurrence of mass casualties, it was necessary to have a headquarters exercising centralized control. In the event of destruction of the central headquarters, control was passed to an alternate headquarters. Under such guidance, medical organizations were used to their full effectiveness, as it was possible to assign them throughout the combat area as needed. Good communications and airlift were also essential for successful operations. In their absence, as occasionally did occur, it was necessary for an isolated unit to rely on its self-sufficiency. Self-sufficiency means, among other things, that each individual of a unit must be well trained in the principles of first aid, for administration to himself and to others. Such training will in many cases provide the only medical care available initially after an atomic bomb strike.

Destruction from Nuclear Weapons

The extent of damage and the pattern of a nuclear war is seen in figure 2, which illustrates the bases of the United States air forces that were destroyed by aggressor atomic air attacks in the first two hours of the maneuver. The magnitude of any single bomb burst shown can be appreciated if a comparison is made to the high-explosive bombs dropped by air during World War II. If every bomber plane of the allied air forces of the United States and the United Kingdom had been loaded to capacity with high explosives and all had dropped their bombs in one satu-

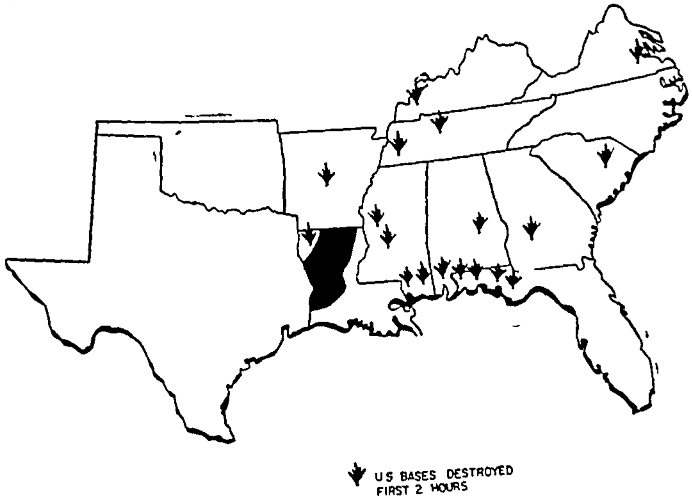

Fig. 2.—U. S. Air Force bases destroyed by atomic bombs in first two hours of Exercise Sage Brush.

ration raid, the result would have been only a fraction of that represented by a single atomic burst in figure 2. Similarly, figure 3 shows the number of atomic weapons used on ground troops during the entire maneuver. Again, the devastation shown is catastrophic. As a result of such action, it is evident that past experiences of destruction covering time periods of months and years are now compressed into periods of minutes and hours. The decisive phase of a war may be over in a few hours or days, as it was in this maneuver. On the other hand, it is possible that a war might be prolonged due to many factors, political or military. In the latter instance, the type of medical support provided in Exercise Sage Brush would have been adaptable to the situation, because of the flexibility of medical units and the availability of airlift. Air transport could have moved medical support as needed and cleared casualties from forward areas to well-equipped hospitals in the rear. Thus, tactical units would have been relieved of a logistical burden and would have preserved their ability for rapid movement and exploitation.

Principles for Organization of Medical Groups

Lessons learned from this maneuver indicate that our Army and Air Force medical organizations in existence and being developed can cope with the problems of nuclear and thermonuclear warfare if certain principles are followed. These principles are as follows: 1. All individuals must be trained in first aid for assistance to both self and others. 2. Organic medical support attached to tactical units must be of the smallest size possible. 3. All other supporting medical units must be mobile, widely dispersed, and centrally controlled. 4. Rapid transportation must be available.

These same principles can apply to the organization of civilian medical groups in preparation for any disaster. If adapted to civil defense, it would mean that first-aid and self-aid training must be given to all citizens. Casualty-treatment units must be organized in advance to be manned by designated physicians and helpers. These units must be widely dispersed in a community and be capable of operating for short periods with communications destroyed. Large hospital units must be organized on a team basis for dispersal or for sending assistance to other areas. Similarly, all means of transportation for both supplies and patients must be organized on a team basis for local or regional use. Plans for centralized control of all elements of medical coverage must be developed in each geographical area. Each community must coordinate with neighboring areas on disaster plans. Local and state governments must be prepared to furnish regional aid. It is conceivable that, as plans progress, a national, central control headquarters will be required to coordinate the individual efforts of military and civil agencies.

Relative to civil defense, it is appropriate to quote I. S. Ravdin,[1] who has outlined the action he felt necessary as follows:

> Civil defense on a local or even a regional basis is, in my opinion, unrealistic. We must develop a plan that will permit the transfer of those concerned with medical care from distant areas and the assignment of those available at the local area. Whether these individuals will be under complete civilian control or whether they will, once they are called to duty, be under military control should be decided before the emergency arises. What needs to be recognized now is that they must be under some type of disciplinary control. The future can not be left to chance.

Summary

Thermonuclear warfare requires that military tactical units be small, dispersible, and self-sufficient and that they possess extreme mobility and flexibility. Medical support must be adapted to this type of organization. This is done by providing in a tactical unit only the medical personnel and equipment to give minimum essential early treatment and preventive medicine supervision. Additional support is given by use of mobile medical units assigned on a regional basis as required, through centralized control. Air transport is used to supply dispersed units and to evacuate patients. Examples of the use of this new type of organization were illustrated for both Army and Air Force units in the large joint maneuver "Exercise Sage Brush" held in the fall of 1955. Civilian communities can organize along similar lines to furnish medical care under disaster conditions. This concept provides for dispersed medical units, use of self-aid, and support through mobile units under centralized control.

ROLE OF THE GENERAL PHYSICIAN IN THE ATOMIC AGE

I. Phillips Frohman, M.D., Washington, D. C.

• *It is essential for all physicians, and particularly the general physician, to be alerted to the new health and hazard problems related to the peacetime use of nuclear radiation. This knowledge will also aid him well in event of atomic warfare.*

The use of radioactive substances alone has increased tremendously in industry, pharmaceuticals, and medicine in general. Employment exposures to nuclear products impose an immediate responsibility to the physician to be aware not only of the side-effects of radiation but more so of the diagnosis and treatment of overexposed patients. The complaints of malaise, lassitude, and anorexia unsupported by the usual clinical causes; gastrointestinal symptoms; dermatological conditions; or bizarre or unrecognized hematological changes in those patients working with or in the vicinity of nuclear radiation should alert the physician to consider these symptoms as perhaps manifestations of overexposure to radiation.

Today the supposed safe limit of 300 mr per week total body exposure is only approximate and not conclusively free of danger. Even those patients not overly exposed may develop "radiophobe" attitudes, with obsessions necessitating careful and patient guidance by the physician.

This is a new branch of clinical medicine, still not propounded in the medical literature nor included in the medical school curriculum, yet it faces some of us today and will face many of us in practice in the near future.

I am extremely grateful to the members of the Section on General Practice for having honored me with the chairmanship in the past year. A number of subjects suitable for presentation as the chairman's address were considered, some were reconsidered, some were written about and the articles published in various medical journals, and others were discarded. In my review of the medical progress of the past decade and the effects of such progress on the general physician, I found that the swift tempo of research has been so overwhelming that it is often difficult for any physician, whether specialist or general physician, to remain abreast. This is particularly true if one tries to grasp the impact on medicine of the development in nuclear physics.

Research in Nuclear Radiation

The amount of research already done in the field of nuclear radiation must be tremendous. To realize this, we have merely to use our powers of logical inference, based on the spectacular results we have been permitted to view. The greatest portion of this research is not published, for reasons of national security.

At a meeting held in Washington, D. C., on April 28, 1955, on "Nuclear Radiation Hazards and Their Political Implications," sponsored by the Federation of American Scientists, Dr. M. Stanley Livingston, professor of physics at the Massachusetts Institute of Technology, remarked in his opening address upon the extreme difficulty of securing enough qualified persons to fill the panel. Many scientists hesitated or were not given clearance to speak on a subject about which so much information was still being classified. Others declined to enter the discussion for fear of involvement in an issue sufficiently controversial to provoke security clearance trouble. Thus we see that much of the work done in nuclear radiation has not been made available to the medical profession in general and cannot have been exposed to the acid test of widespread clinical observation.

Present Dangers in Atomic Medicine

Dr. Bentley Glass, geneticist and professor of biology at the Johns Hopkins University, states that there are two grave dangers in the present situation. One is our ignorance about the effects of radiation, and ignorance is always a danger. The other concerns the matter of "average" dosage. As the number of test explosions increases and the long-lived isotopes accumulate and as the industrial atomic energy plants multiply and the disposal of atomic waste products becomes more and more a critical problem, the cumulative exposure to radiation may exceed the "safe dosage" of 0.2 r per year, which was the average amount received by the Oak Ridge and Hanford workers in 1949.[1] This leaves me with the frightening thought that, when the bulk of atomic research is finally dumped into our laps and literature, we physicians will have to assimilate the mass of it, rather than the slow piecemeal of it as we would prefer.

I firmly believe that the discovery of nuclear radiation will produce the greatest change in the lives of mankind since the discovery of fire. I believe that the amount of productive atomic and radiation research and the use to which this research will extend in medicine in the very near future will far surpass that of any group of new drugs discovered in the past 50 years—and this includes the steroids and antibiotics. I also believe that our historians will refer to the 20th century as the atomic rather than the antibiotic age of medicine.

No doubt, the atomic age will be said to have begun at that point in time when man learned not only how to release, but also how to control, the energy that binds the nuclei of atoms. The "control" part appears to be the knottier of the two problems at present. In fact, the peacetime atom may thrust on the general physician a whole new set of health and hazard problems, many of considerable magnitude. We can be certain that in the near future we will be living in a world more radioactive than at present, since the use of atomic or nuclear radiation will steadily increase in industry, hospitals, pharmaceutical manufacturing plants, metallurgical research, biological research,

---

Chairman's address, read before the Section on General Practice at the 105th Annual Meeting of the American Medical Association, Chicago, June 12, 1956.

atomic submarines, aircraft carriers, plastic industries, and many other aspects of our technical culture. In all of these, we physicians may find the invisible hazards more insidious in onset and more frightening in climax than any of the dramatically visible occupational hazards we occasionally encounter at present. Even with the best equipment and protective devices, there is always present the potential danger of radiation leakage, unforeseen accidents, and that common frailty—human carelessness. Furthermore, we have with us always the accident prone, and no safety equipment has yet been devised that will shield them from themselves.

Perhaps I had better pause right now to assure you that this paper has nothing to do with atomic warfare. It is not my purpose to discuss the role of the military in the use of nuclear power but rather the role of the general physician, the "front line physician," in this, the atomic age, which is rushing down the corridors of time to meet us head on. And we, I might add, are unprepared for the encounter. Most of us are babes in the wood where the problems and potential results of exposure to nuclear radiation are concerned. If I can succeed in alerting even a few general physicians to the fact that a new era is at hand and that we are not prepared, I shall have accomplished the purpose of this address.

Effects of Exposure

In any discussion on the effects of radiation, we must always keep in mind that radiation is absorbed, and that its absorption takes place in the basic biological unit of life, the body cell. The pharmacological reaction to radiation that takes place in the body cell is much like that of drugs. Both produce local as well as general (systemic) effects. These effects may appear immediately or after varying amounts of time, both may produce morphological as well as functional changes, and drugs as well as radiation produce reversible as well as irreversible effects. Here the similarity between drugs and radiation ends. The reversible effects of cellular drugs (such as anesthesia) is a common fact in the field of pharmacology and is familiar to all physicians. But the reversible effects of radiation, though theoretically possible, have been demonstrated only through artificial interference by such means as cooling or washing the irradiated tissues. Unless such interference is introduced, irradiated cells and tissues are damaged irreversibly.[2]

In many instances, the apparent increase in function of irradiated cells is an expression of premature aging.[3] After exposure to radiation doses that do not produce cell death immediately, vital functions proceed at an accelerated pace until cell death occurs. Vital energies are exhausted prematurely due to the impact of irradiation and the disorganization of factors controlling the orderly use of these energies. We are well acquainted with the example of how menstruation may be stimulated when irradiation of the ovaries is attempted. Here the therapeutic result is achieved at the price of partial destruction of the atretic graafian follicles, which causes the amenorrhea, and at the possible further price of inducing hereditary changes in the ovary of the irradiated woman.

The knowledge of the side-effects of irradiation is an unqualified necessity and is indispensable in the clinical diagnosis and treatment of patients exposed to radiation. The effects of radiant energy on living matter, particularly of humans, is of the greatest importance to all physicians, especially the general physician. We must be capable of evaluating these effects as either therapeutic or toxic. The ever-increasing use of radioactive substances in recent years is borne out by these figures. It has been shown that the use of radioactive iodine has increased from a few millicuries to almost 50,000 mc. per month; and that radioactive phosphorus has increased to almost 13,000 mc. per month; and radioactive gold, which was almost unknown in 1950, is now being distributed at the rate of more than 50,000 mc. each month.[4] This vast increase in the use of these radioactive drugs in so short a time certainly shows that there is a definite radioactive pharmaceutical business in progress.

The utilization of ionizing radiation for the purpose of sterilization of drugs and foods, suture materials, and other pharmaceutical agents opens new fields for the peacetime use of atomic energy. I would like to mention some of the sequelae of the atomic age of concern to physicians in general practice.

In a recent issue of THE JOURNAL, a case of aplastic anemia secondary to intravenous therapy with radioactive gold was reported.[5] On Jan. 11 and 12, 1956, newspapers carried the story of four men who, having been exposed to radioactive cobalt, faced weeks of uncertainty as to the results of this exposure. It seems that one of these men needed a piece of string and picked up the first piece he came upon at his place of work. This piece of string, unfortunately, had a capsule of radioactive cobalt attached to one end. This radioactive cobalt capsule was used in the steel plant to detect defects in structural steel and piping. How long he held it in his hand is unknown, but it eventually reached his pocket, and when he arrived at his car he transferred the string and cobalt to the glove compartment. The other three men were riders in the car and thus were innocently exposed to radiation. Here is but one example of the carelessness and ignorance I mentioned, and this may very well be repeated many times over in the next decade. This example is cited in order to show that we general physicians must be prepared at all times in the future to see patients in our offices who are walking demonstrations of careless and ignorant exposure to these atomic forces.

Examination of Patient

Let us now explore the potential physical findings we general physicians might uncover in this type of patient were he to visit us in our offices, not knowing he had been exposed. In this paper I cannot cover completely all of the findings, diagnoses, and treatment of radiation exposure. Physicians and scientists much more learned in this field than I am have contributed a great deal to present-day medical and scientific literature. It is my purpose to [illegible] few of you to learn all you can about this [illegible]ching atomic era in medicine so that [illegible]ared for the oftentimes [illegible] sympt[illegible]

Just as important as the meticulous history will be the place of employment, the type of material with which the patient might be in contact, and whether the patient is in his routine work exposed to ionizing radiation in any of its forms. Some of the most important early complaints our patients might present could be malaise, anorexia, and lassitude. When these complaints are not supported by other usual clinical causes, they may very well be the first expressions of an overexposure to radiation. These signs are of the utmost importance: Exposure in any of these patients may be due to careless handling of material, an undetected breakdown of protective measures, or simply the expression of unusual constitutional sensitivity of the patients to ionizing radiation. This could occur in such persons as those with vagotonic conditions—in spite of observation of and strict adherence to all safety measures. Later there may be a low-grade nausea, possibly with vomiting or diarrhea or both, which might very well be attributed erroneously to other diseases or infections. But if we are vigilant and never fail to consider the irradiation exposure potential of patients employed where such exposure is possible, much time will be saved in arriving at the probable diagnosis.

A careful examination of the skin, hair, and fingernails is mandatory in any patient working in plants using radiation. The presenting complaint may be simply itching of the skin, a burning sensation, or perhaps nothing but a slight reddening of the irradiated exposed areas. The physician might be confronted by an unexplained pigmentation, one not conforming to the usual problems in dermatology in general practice. Here again the accurate history is most important. Symptoms such as abnormal epilation of the scalp in women or of the face in men should alert the physician to the possibility of radiation exposure.

Exposure may produce a burning sensation of the eyes with undue lacrimation.[6] Any cataract formation, especially on the posterior pole of the lens in young persons, should arouse suspicion of exposure to radiation. The reaction in the blood stream will be of the utmost interest to the general physician. The systemic effects of prolonged exposure to irradiation are serious. There may be aplastic anemia with fatal termination.[7] And chronic exposure may increase the incidence of leukemia.

It has been shown in the writings of Henshaw and Hawkins [8] that the incidence of leukemia in radiologists is approximately 8 to 10 times greater than in other physicians. Must we not consider those working in nuclear industry, unless closely observed and more closely protected, in the same category? The exact dosages required to produce blood alteration with a depression of the peripheral blood elements are not known, but the degree of depression of these blood elements is believed to be the best index of the severity of acute radiation injury and perhaps an index to the amount of exposure.

Complete preemployment blood studies on all of our patients working with, in, or about radiation plants will be of critical importance. These should consist of hematocrit determinations and leukocyte, neutrophil, lymphocyte, and platelet counts. They should, in fact must, be done by physicians experienced in such blood studies; otherwise, the patient's specimens should be sent to a pathologist. Any blood smears from patients exposed to radiation that show a blood picture unrecognizable or bizarre to the general physician should most certainly be dispatched to a qualified pathologist, preferably one schooled in the effects of radiation exposure on the blood. Following this, bone marrow, liver, and spleen biopsy studies may be in order. In the preemployment physical examination of patients applying for positions in atomic nuclear reactor plants or in industries using radiation, it might be wiser to exclude from such employment any person whose total white blood cell count is above or below the recognized upper and lower limits of normal until definite rules and regulations are established by proper authorities for this condition.

Effects of Radiation on Sterility and Genes

The always puzzling problem of sterility will be an added burden of diagnosis and treatment to the general physician and medical men in general, especially sterility in the male patient. It is, and has been, known for many years that the reproductive organs are highly sensitive to radiation. The genes, too, are susceptible, with the production of radiation-induced mutations. The effects in the first generation may not be detectable, but how are we to decide just what will be inflicted on future generations—even if the ancestral dose was small? Literature [9] tells us that the progeny of radiologists and others exposed to radiation are subject to a significantly higher percentage of congenital malformations than those of persons not so exposed. To the general physician, the implications of this finding will be magnified alarmingly when he first encounters malformations and realizes that they will appear even more frequently in subsequent generations. It is not inconceivable that the actual morphology of our descendants may depend upon the vigilance and acuity of physicians practicing today. We must be equipped and ready to detect even the slightest symptom of overexposure, for nowhere in the literature could I find evidence that a method of countering radiation's irreversible effects was even in the offing. There may come a time, however, in our rapidly expanding and forward-moving industrial atomic age when certain short cuts in protection from radiation may occur. This is the danger period.

Maximum Dosages

There is such a thing as the maximum permissible dose of radiation, and this is defined by the International Commission on Radiological Protection as "that dose of ionizing radiation that, in the light of present knowledge, is not expected to cause appreciable bodily injury to a person at any time during his lifetime."[10] It is further stated that the "maximum total dose to which the body may be exposed continuously or intermittently is currently established as 300 mr per week, whereas exposure to the hands and forearms may be five times this amount and still be considered to be within safe limits." But—and here is the most important statement: "These supposed safe limits are only and at best approximations, and there is no conclusive evidence that even such levels are completely free of danger. This maximum permissible exposure rate has been modified and reduced in the past. In the near future with the expanded use of ionizing radiation this permissible exposure rate may have to be modified and reduced further."

Safety Measures

For the purpose of the general physician in his daily practice with those working in or about radiation, irrespective of the safeguards, the wisest precaution to protect patients would be the advice of Ritvo, D'Angia, and Rhodes,[7] "that excess radiation comprises any radiation which can be avoided." It is likewise important that all plants dealing with radiation—in no matter what form—adopt safety patterns calculated to minimize or eliminate all dosages, no matter how small, how infrequent, or how harmless these dosages appear to be.

Many devices have been employed to measure exposure. This represents no problem. The difficulty lies in measuring the individual—and the machine has not been invented that can do this. The pocket dosimeter and the Victoreen ionization chamber can both register the amount of radiation John Doe has absorbed, but John Doe himself remains as unpredictable as he has always been, physicians and psychologists notwithstanding. What his particular physiological reactions will be to even the so-called minimum dose always remains uncertain. What is harmless to mankind may be lethal to one man—and that one man may be your patient, or mine. Thus, to rely upon any instrument to report the amount of exposure and to accept this without further investigation of the individual himself would be to abandon the caution upon which our profession is based and to do a grave injustice to the patient.

Other Problems

Another problem we will undoubtely face will be the radiophobes—patients obsessed with a probably groundless fear of overexposure. This can be complicated by the known effects of radiation on the reproductive organs, since the relationship between sex and the psyche is a familiar one to all of us. Distinguishing a person with bona fide radiation poison from the radiophobe will require skillful diagnostic techniques, patience, and understanding. It is for this reason that the general physician must familiarize himself with the fundamentals of medical radiation biology in order to give competent and confidence-inspiring advice to these patients.

In the past few months in newspapers throughout the country much has been written about proposed nuclear power plants to be erected in the immediate future in this country. True, while we are happy about the enrichment of our national economy through the uses of atomic energy, we, as physicians, must be cognizant of the potential dangers inherent to this industrial evolution. Two very important characteristics differentiate the potential hazards of nuclear fission products from the more conventional industrial poisons. First, fission products in nuclear reactor plants do not assault the senses, even in lethal doses and concentrations. Second, nonlethal doses or exposures can produce permanent injuries that may not become evident for many years after the original exposure. Furthermore, the nuclear fuels, such as plutonium and uranium –233, are highly toxic if inhaled or ingested.[11] It is important for all physicians to know and understand the toxicology of these reactor fuels and of the other products used.

Medical Education and Radiation

To prepare the future physician for the atomic era of medicine, education in the field of radiation biology is a "must" for the medical student, the intern, and the resident. Yet, I wonder how many, if any, medical schools in this country are properly staffed with a separate department to teach radiation biology and the pharmacodynamics of nuclear activity as applied to medicine. Must we wait until the full impact of the entire mass of research envelopes us completely and the literature becomes too complex for orderly sorting before our schools inaugurate adequate teaching facilities and staff in this all-important new field? The longer we wait, the more difficult the task of weighing, analyzing, and sifting the information so that it can be effectively imparted to students.

At the moment we seem to be ensnared in an incongruous situation wherein the physical scientist controls the "atomic pile of education and knowledge," and the physician passively stands aside. Would it not be eminently appropriate to have physicians engaged in full-time medical research in radiation biology teach those who must combat the human side-effects of that research? Physicians may then instruct medical students, interns, residents, and nurses. Needless to say, the obvious benefits would apply indiscriminately to all—to the laboratory scientists and physicians as well as to the general public.

Recently a nine-man study group presented their findings, suggestions, and conclusions to the Joint Atomic Energy Committee[12] on the peaceful uses of atomic energy. This panel maintained that "the speedy progress in atomic medicine depends on three principal factors: training of an adequate number of doctors, nurses, and technicians; construction and staffing of adequate research facilities; and provision for rapid communication of the most advanced medical knowledge." This group further stated, and I quote, "It is our strong feeling, however, that medical institutions and research centers should not assume a passive role and expect the government and more specially the (Atomic Energy) Commission, to assume all or even a major portion of the responsibility for providing research facilities, equipment, and materials." To further substantiate my feelings in the matter of nuclear energy radiation—its use and misuse—this same nine-man group presented a definite six-point program to the Atomic Energy Commission in their report. They stated:

"1. Provide all medical schools with adequate facilities for training in atomic medicine techniques. 2. Create additional research centers with appropriate equipment, including reactors. 3. Design low-cost atomic medical equipment suitable to the needs of the 6,100 hospitals and medical clinics without atomic facilities and provide at least minimal facilities to this group as rapidly as possible. 4. Make available at reasonable prices the

, by management of the patient and his family, a variety of rehabilitative measures—in other by a totality of psychiatric therapy in which the al treatment merely represents an essential ating measure, especially if the physician has eded in avoiding certain undesirable side-effects night potentially aggravate specific psychological s.[1] Shock therapy itself, therefore, does not relieve primary traumatic neurosis that originally evoked the warning or tension anxiety (fig. 1), but it does interrupt the vicious cycle between the warning anxiety on the one hand and panic and depression on the other (fig. 2), thus relieving the secondary traumatic state of the ego,[3] i. e., the secondary traumatic neurosis induced by the warning anxiety itself.

WARNING OR TENSION ANXIETY
PRIMARY TRAUMATIC NEUROSIS

Fig. 1.—Relationship of trauma, anxiety, panic, and depression. + denotes excitation, — denotes inhibition.

How does shock therapy accomplish this result? The paralysis of the ego in the form of depression, resulting as it does from the impact of excessive quantities of excitation by warning anxiety (fig. 1), has all the earmarks of a paradoxical reaction in the Pavlovian sense, in that it appears to be a state of profound inhibition or paralysis induced by excessive excitation. Furthermore, we are justified in assuming that warning anxiety, which is largely unconscious and which can be precipitated or aggravated by an injection of epinephrine, is essentially a subcortical phenomenon. Panic and depression, on the other hand, pervade the conscious mind and cannot be precipitated or intensified by intravenously injected epinephrine and hence appear to be mediated and perceived chiefly within the cortex of the brain.

Electroshock diminishes cortical excitability, and it appears to be for this reason that the subcortical warning anxiety can then no longer overstimulate the cortical ego into panic or depression. The ego and its defenses appear strengthened after electroshock therapy, for the excitation threshold of the cortex has been raised (fig. 2). This dynamic alteration in the threshold gives the ego an opportunity to strengthen and regroup its defenses,[4] a process that can be aided by psychotherapy, although it often takes place spontaneously after successful electroshock therapy.

Warning or tension anxiety, while no longer disruptive to the ego because of the latter's raised threshold to stimulation, can of course still be perceived at certain stages or intensities of treatment. This anxiety may come even more prominently to the fore (fig. 2) because its presence is no longer obscured through its secondary paralyzing effect upon the ego, which in turn had an inhibitory effect upon the anxiety due to spread of inhibition (fig. 1). This obviously explains the apparently reciprocal relationship between warning anxiety and depression that I pointed out earlier, based on the fact that I was able to convert and reconvert one into the other by specific physical measures.[2]

The residuum of warning anxiety, conscious or unconscious, that the patient is likely to be left with after electroshock therapy has to be dealt with in one way or another. Often in his improved state the patient is able to look at the underlying issues that aroused the warning anxiety in a new light, much as we all are able to do with minor problems after a good night's sleep or when we find that something we had dreaded did not materialize. This resurvey in turn diminishes the anxiety engendered by the issue. A beneficent cycle has been set up. A similar result can be brought about by follow-up psychotherapy in patients who may not be able to attain this strengthening and maturing by themselves.

In particularly severe illnesses, massive shock therapy may be utilized to the point where not only excessive response to, but even awareness of, warning anxiety is suppressed temporarily. The disadvantage of this last method is that the warning anxiety is merely suppressed and during the convalescent phase is likely to erupt again disturbingly and precipitate relapse. I prefer release and ventilation of the warning anxiety by the added use of nonconvulsive-stimulation treatment, which enables the therapist to deal simultaneously with it and the underlying issues, thus paving the way for subsequent psychotherapy of the primary traumatic conflict.

Tranquilizing Drugs

The action of the new tranquilizing drugs, chlorpromazine and reserpine, is fundamentally different from that of shock therapy, in that these drugs appear to suppress the primary, epinephrine-precipitable, subcortical warning or tension anxiety while exerting only an indirect influence on the secondary cortical manifestations—the traumatic state of the ego—in inverse proportion to the degree to which important ego functions have been disrupted in the direction of paralysis or inhibition by the anxiety. For this reason tranquilizing medication, especially with chlorpromazine, is most effective in manic states. This may be due to the fact that the manic state is a condition most directly power-driven in the direction of excitation by epinephrine-precipitable tension anxiety, as I pointed out elsewhere,[5] and in which important ego functions are least weakened. Conversely, for the same reason, and in remarkable accord with the fact that inhibitory cortical processes are more readily extinguishable than excitatory ones,[6] manic psychoses are least readily relieved by electroshock therapy, which is an extinction type of treatment, unless the treatment is carried to the point of obliterating even the mere perception of warning or tension anxiety. Another reason for the superb clinical results of chlorpromazine therapy in manic patients is that manic psychoses tend to be of naturally short duration. Hence, if the manifestations of the psychosis can be suppressed for the natural duration of the manic episode, the patient can continue to live a rather normal life and may even be able to keep on working without experiencing either the social disadvantages of morbidity or the undesirable suppression of cortical functioning produced by electroshock.

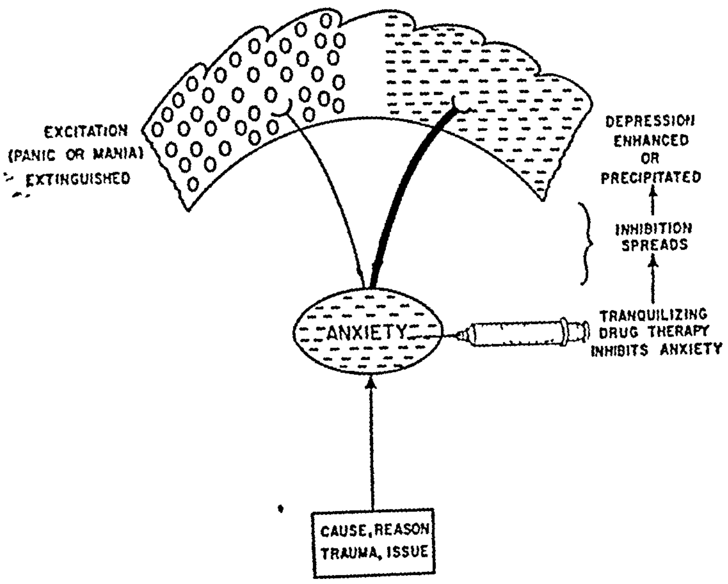

Fig. 3.—Effect of tranquilizing drug therapy. — denotes inhibition; O denotes extinction.

Depression is at the other end of the scale of effectiveness of the new tranquilizing drugs. Chlorpromazine and reserpine not only are entirely ineffective in most cases of depression but are actually contraindicated because they may aggravate the condition. The reason for their ineffectiveness is obviously the fact that, in depression, paralysis of the ego is most profound, the ego being in an inhibitory state already. Inhibition of ego functions is not only not relieved but is actually aggravated by these drugs, because not only has this inhibition of ego functions become independent of continued overstimulation of the ego by the warning anxiety that originally paralyzed the ego into depression but, by a process of negative induction leading to spread of inhibition, the inhibited state of the ego has extended to include the original warning anxiety as well (fig. 1). This fact explains the reciprocal relationship of anxiety and depression in contradistinction to the simple vicious-cycle type of relationship that exists between warning anxiety and panic (fig. 1). Thus it comes about that further suppression of the original warning anxiety by means of drugs will actually deepen the existing depression (fig. 3), or it may even precipitate depression. Conversely, enhancing the warning anxiety by injection of epinephrine, for instance, may relieve depression temporarily.

Depression is indeed the most significant mental and emotional complication arising from the use of these tranquilizing drugs. If administration of chlorpromazine, for instance, is continued too long after control of a manic psychosis (as occurred with three patients in my own experience, in whom this drug was administered over periods ranging from four to seven months in an attempt to tone down mild residual hypomanic states) or if reserpine is given to depression-prone individuals for relief of hypertension,[7] these drugs may precipitate depression, which, however, can be promptly terminated by withdrawal of the drug. Gastrointestinal symptoms of withdrawal of chlorpromazine can be avoided by administration of Donnatal (a combination of hyoscyamine sulfate, atropine sulfate, hyoscine hydrobromide, and phenobarbital), which is then rapidly withdrawn.

The new tranquilizing drugs are less consistently effective in catatonic and excited schizoaffective states than they are in manic states. In catatonic and hallucinatory paranoid states I have found reserpine relatively more effective than chlorpromazine. In most other anxiety and panic states and in related regressive neurotic and psychotic syndromes, I have found the use of chlorpromazine and reserpine generally unsatisfactory from the long-range point of view, with a few remarkable exceptions in which patients responded very well. All those who did respond well were marked by agitation and overactivity, and these are the patients who seem most amenable to chlorpromazine therapy. Reserpine, on the other hand, was useful in some patients in phobic states. All these patients, however, had one thing in common with manic patients: while the ego boundaries had been breached by panic anxiety, any secondary paralysis of important ego functions was absent or relatively slight, the clinical picture being dominated by excitation. As might then be expected, none of the obsessive-compulsive patients was benefited at all, not even temporarily.

The great variety in the response of patients with neurotic and borderline states to tranquilizing drugs may be in part explained by the fact that one of the more important effects of these drugs is that they enhance suggestibility. West[8] has shown that the use of these drugs increases the ease with which these patients can be hypnotized or otherwise influenced by suggestion. This highlights the fact that additional therapeutic actions and/or attitudes of the physician may play a decisive role.

Chlorpromazine is useful in relieving states of excitation in the psychoses arising from chronic alcoholism and in states of pathological alcoholic intoxication[9] as well as in cases of drug addiction for relieving nervous-system excitation released by withdrawal of narcotics.[10] Both chlorpromazine and reserpine are useful in senile psychoses. In a patient with presenile sclerosis (Alzheimer's disease) with marked agitation, overactivity, and increased stream of talk, a remarkable degree of social improvement was brought about by administration of chlorpromazine. Chlorpromazine and reserpine have also been found helpful in the control of chronically disturbed patients in mental hospitals. In the majority of these patients, this method of control merely suppresses symptoms without bringing about actual recovery; however, physicians who have used large doses of reserpine in such hospital populations of persons with apparently chronic, incurable schizophrenia have consistently reported a social recovery rate of 20%, so that many such patients are able to return home after many years of hospitalization.

Other New Drugs

A number of additional new drugs have become available that differ from the tranquilizing drugs in varying degrees. I should like to divide these into three groups: (1) relaxant drugs, (2) ataraxic (deconfusing) drugs, and (3) antiphobic drugs. The action of relaxant medication, such as that exemplified by the new drug meprobamate (Miltown),[11] is similar to that of the tranquilizing drugs, except that its inhibitory effect is less profound. This is an advantage in the psychoneuroses, in which marked reduction of drive such as that brought about by tranquilizing drugs is often anxiety provoking and thus tends to counteract the desired effect of the medication. Because of its less profound inhibitory action, meprobamate also does not tend to precipitate or aggravate depression, but for the same reason it is also much less effective in the treatment of psychotic states of excitement.

Ataraxic (deconfusing) action has been described as the characteristic effect of Frenquel[12] [α-(4-piperidyl) benzhydrol hydrochloride]. In contrast to the tranquilizing drugs, Frenquel does not depress the activity of the hypothalamus either clinically or in the electroencephalogram; it counteracts the effects of lysergic acid diethylamide (LSD-25) and of mescaline without inducing sedation and restores the resting activity in the electroencephalogram after its disruption in the form of enduring arousal by lysergic acid diethylamide or mescaline.[13]

Antiphobic medication, as with Benactyzine (2-diethylaminoethyl benzilate hydrochloride), is fundamentally different from tranquilizing medication in that it selectively abolishes "neurotic" inhibitory avoidance responses engendered by stress without inhibiting the orienting response and conditional reflex responses.[14] Consistent with the conceptual scheme presented in this paper, this drug has proved itself in the hands of others[15] as well as myself to be a mild antidepressant in clinical states of depression in human beings, of both manic-depressive and involutional type. Further studies of these and related compounds promise to shed further light upon the neurophysiological and biochemical aspects of emotional and mental disorders and to aid in their treatment.

Summary

Electroshock therapy relieves the secondary traumatic state of the ego (panic and/or depression) by reducing the excitability of the nervous system, especially the cortex. Unconscious (subcortical, epinephrine-precipitable) warning anxiety can then no longer overstimulate the cortical ego and thus frighten it into panic or paralyze it into depression, as it did formerly along the lines of Pavlov's paradoxical reaction. The ego and its defenses appear strengthened after electroshock therapy, because its excitation threshold has been raised. The new tranquilizing drugs (chlorpromazine and reserpine) relieve the primary, unconscious, subcortical, epinephrine-precipitable warning and tension anxiety that impels states of excitation. They are thus capable of relieving states of agitation and overactivity, especially manic psychoses and organic-toxic states, in which secondary inhibitory or disorganizing effects upon the ego are slight or readily reversible. The action of certain newer groups of drugs, which may be classified as relaxants (such as meprobamate [Miltown]), ataraxic (deconfusing) (such as Frenquel [α-(4-piperdyl) benzhydrol hydrochloride]) and antiphobic (such as Benactyzine [2-diethylaminoethyl benzilate hydrochloride]), is different from that of the tranquilizing drugs. They require further study of their psychophysiology and clinical indications.

CLINICAL NOTES

MEASUREMENT OF BLOOD PRESSURE IN OBESE PERSONS

Kenneth W. Trout, M.D.
Charles A. Bertrand, M.D.
and
M. Henry Williams, M.D., Valhalla, N. Y.

The clinical measurement of arterial blood pressure by the auscultatory method is known to be subject to error. The initial technique, introduced by Riva Rocci,[1] using a 5-cm. cuff, was subsequently demonstrated to be erroneous by the investigations of Von Recklinghausen in 1901.[2] Von Recklinghausen established the clinical method for measurement of blood pressure by showing that sufficiently accurate results were obtained by means of a wider cuff. He postulated that the cuff transmits pressure directly to the artery and that this is not modified by the soft tissue, provided the soft tissue is of normal elasticity and the proper cuff width is employed. The standard 13-cm. cuff is now widely used, although falsely high blood pressures may be obtained in obese patients[3] and low values may be obtained using the 13-cm. cuff in children with small arms.[4]

The object of this study was threefold: (1) to demonstrate the error in taking blood pressure by the conventional method in subjects with large arms; (2) to investigate the accuracy of a new forearm method for measuring blood pressure; and (3) to explore the role of tissue composition as a cause of error in subjects with large arms.

Method

In the forearm method the standard 13-cm. cuff was placed on the forearm with its midpoint 13 cm. from the olecranon process, and the blood pressure was determined by either auscultating or palpating the radial artery. For comparative purposes the blood pressure was obtained in 100 persons, both by the usual method (cuff on upper arm and auscultation of brachial artery) and by the forearm technique. The circumferences of the upper and lower parts of the arm were determined by a tape measurement 13 cm. proximal and distal to the olecranon process. The pressure readings were taken in routine examination of 100 consecutive patients and staff members of a general hospital.

The brachial or radial intra-arterial pressure was determined in 14 additional persons. In eight persons there was no significant difference between the forearm and upper-arm pressure readings, and these served as a control group. Six patients had a marked discrepancy between the pressure readings at the two sites and comprised the second group. These six were originally selected because of extreme obesity. The blood pressure was determined after the patient rested either supine or sitting comfortably with the arms supported until the blood pressure reached a steady state. The circumferences were measured as already described, and numerous blood pressure readings were taken at the two sites on both arms with a standard width cuff with metal clips and a mercury manometer. An arterial needle was then introduced, after procaine hydrochloride infiltration, into the brachial or radial artery, and the arterial pulse was recorded by means of a Statham strain gauge and amplifier. At the same time, or immediately before and after, the blood pressure was determined by the cuff method in the same arm.

In order to study the role of tissue elasticity, six normotensive subjects were chosen whose blood pressure was the same in each arm. One of the upper arms was loosely wrapped with cotton to a circumference of 45 cm. The blood pressure was then taken with the 13-cm. cuff and the cuff progressively tightened, thus compressing the cotton. Serial blood pressure determinations were recorded in both arms, the opposite arm serving as a control. In six normotensive patients one upper arm was increased in size to 45 cm. with less compressible gauze wound firmly around the arm, and the blood pressure was again recorded simultaneously in both arms.

Simultaneous Measurements of Blood Pressure in Upper Arm and Forearm and Recording of Intra-Arterial Pressure

* Eight normal subjects who had no significant difference in blood pressure readings by the three methods.

† Six obese subjects who all had false elevation of the blood pressure measured in the upper arm.

Results

In 79 of 100 subjects there was a difference of 10 mm. Hg or less in systolic pressure taken by the standard as compared with the forearm technique. Seventeen subjects showed a difference of 10 to 20 mm. Hg, and four subjects had a difference of over 20 mm. Hg. In these four subjects the upper arms were obese, the arm circumference ranging from 28 to 36 cm. in each instance, and the pressure was always higher in the upper arm. Six subjects had muscular arms measuring over 35 cm. in circumference and yet had less than 10 mm. Hg difference between upper and forearm measurements.

The table shows the results of the intra-arterial pressure determinations and of the pressures recorded

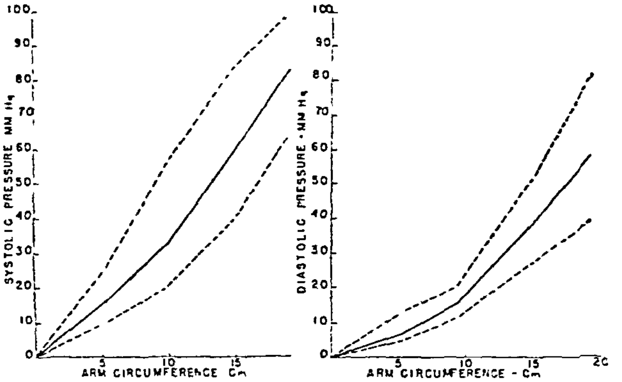
in the upper and lower arm with the sphygmomanometer in 14 subjects. In the patients with a difference in pressure at these two locations, the forearm pressure correlated closely with the intra-arterial pressure. In all members of this group the body surface area was 2.1 sq. m. or above and the circumference of the upper arm exceeded 38 cm. In addition, the upper arms of these six individuals were flabby and consisted, for the most part, of rolls of fatty tissue. The figure indicates the systolic and diastolic errors (artefact) encountered in the normotensive subjects whose upper arms were increased in circumference by adding compressible cotton. As the arm circumference was progressively increased with cotton, similar systolic and diastolic overshoot, or artefact, occurred. When this was repeated with the less compressible gauze there was only a negligible (5 to 8 mm. Hg) rise in pressure until the gauze became 15 to 20 cm. thick, at which point there was a 20 to 40 mm. Hg systolic error and a 20 to 30 mm. Hg diastolic error.

Comment

In 1941 Ragan and Bordley[3] demonstrated the error incurred by taking the blood pressure in large arms with the standard 13-cm. cuff. After investigating such patients with a 20-cm. cuff, they concluded that the 20-cm. cuff did not regularly increase the accuracy of the determination and was apt to give erroneously low reading, particularly in obese patients with actual hypertension. The forearm technique, herein described, appears to give accurate systolic and diastolic readings, so that it can be used when the standard technique reveals hypertension in obese persons with large flabby arms. The reasons for such falsely high pressure readings are not entirely clear.[5] The patients in the present study in whom there was a large error in upper arm readings all had flabby tissue in addition to having large upper arm circumferences. This led to the study of blood pressure readings in normal subjects made artificially obese by wrapping the arm with cotton and gauze. It would seem, from the large error introduced by the cotton as opposed to the small error produced by the gauze, that there is a loss of pressure across compressible substances that may result in falsely high readings. The finding of comparable blood pressure recordings in upper and lower arms in well-muscled individuals with large arm circumferences tends to support this hypothesis.



Left, error in systolic pressure caused by wrapping the arm under the cuff with cotton. The solid line represents the mean of results obtained in six subjects, and the broken lines are the maximum variations recorded. *Right*, error in diastolic pressure caused by increasing the arm circumference with cotton.

Summary and Conclusions

Falsely high blood pressure readings may be obtained in people with obese upper arms. In markedly obese individuals, the true arterial blood pressure may be more accurately determined by measuring blood pressure in the forearm rather than in the upper arm. Tissue composition as well as the arm circumference may contribute to the erroneously high blood pressures recorded in obese subjects.

DIAGNOSTIC VALUE OF BULBOCAVERNOUS REFLEX

Jack Lapides, M.D.
and
John M. Bobbitt, M.D., Ann Arbor, Mich.

Difficulty in urination is often the first clinical manifestation of a lesion of the sacral part of the spinal cord. No other obvious sign or symptom may be present, since the motor defect can be too low to involve movements of the lower extremities, and the sensory deficit, if present, is in the perineal region, an area where anesthesia is not discovered readily by the patient. Even a complete physical examination might not disclose the lesion, since one ordinarily does not test for sensory deficits in the saddle area. Since obstructive uropathy is the usual cause for a decrease in size and force of stream, the patient undoubtedly would be subjected to a urologic investigation. Endoscopy and cystometry might lead to a correct diagnosis if bladder sensation were absent. However, if sensation were intact and only the motor side involved, then the diagnosis might be missed and an unnecessary prostatectomy performed.

In the child, dysfunction of the sacral part of the spinal cord is seen most commonly with spina bifida and myelomeningocele, while, in the adult, trauma, neoplasm, and herniated intervertebral disk are the usual etiological factors.

Every patient with a history of hesitancy in urination, decrease in size and force of stream, and straining to void or urinary retention should be subjected to an examination for intactness of the sacral part of the spinal cord, for the motor and sensory neurones concerned with urination are situated at sacral spinal seg-

ments 2, 3, and 4. The integrity of the sensory component can be ascertained by testing the saddle area for reaction to pinprick. An effective method for determining the status of the motor side involves the use of the Bors [1] modification of the bulbocavernous reflex.

When the glans penis in the normal male or the clitoris in the female is compressed firmly between thumb and index finger, reflex contraction of the bulbocavernosus and external sphincter ani muscles occurs. The shortening of the bulbocavernosus muscle is difficult to feel, whereas tightening of the anal sphincter is readily perceived by placing the index finger in the distal portion of the anal canal or the anus. Although the reflex test can be done by one individual, it is best to have two people perform the examination: one to squeeze the glans penis and the other to note the contraction of the anal sphincter. Occasionally the response is quite delicate, and one individual may not detect it if he is preoccupied with eliciting the reflex.

In order to obtain a good response of the anal sphincter, the patient must be relaxed, for the reflex contraction will not be felt if the musculature of the pelvic floor is already in a contracted state. In addition, the examiner should not compress the glans penis more frequently than once every four seconds, in order to allow the reflex arc an adequate recovery period.

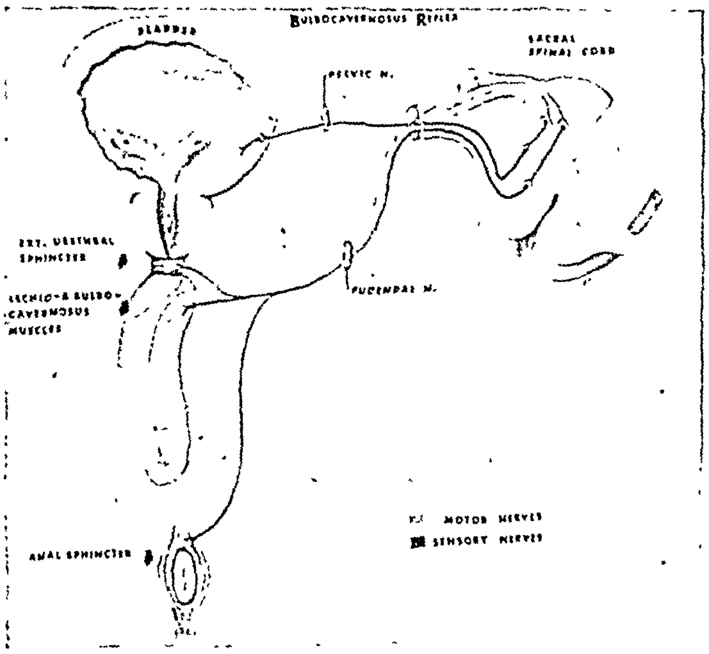

Diagram illustrating the components of the bulbocavernous reflex arc and its relationship to the innervation of the bladder.

The bulbocavernous reflex arc is depicted in the figure and is composed of fibers from the pudendal nerve. When deep pressure is applied to the glans penis or clitoris, subcutaneous Pacinian corpuscles are stimulated to send sensory nerve impulses along the dorsal nerve of the penis or clitoris to afferent neurones situated in the posterior root ganglions. These sensory neurones, in turn, stimulate (through internuncial neurones) motor neurones of the external anal sphincter and bulbocavernosus muscles. The motor impulses are transmitted along fibers of the deep perineal branch of the pudendal nerve. The synapses of the bulbocavernous reflex arc are situated in the sacral part of the spinal cord; occasionally the synapses may lie as high as L-5.[2]

The urology section at the University of Michigan Medical Center has found the bulbocavernous reflex so informative it has been incorporated as part of the routine physical studies of patients with urologic complaints. The value of the bulbocavernous reflex is demonstrated by the following two cases seen recently.

Report of Cases

CASE 1.—A 48-year-old man was referred to the Veterans Hospital with the diagnosis of prostatism and acute urinary retention. The patient related that he had noted the onset of hesitancy, dysuria, and straining to void about three weeks prior to admission. His micturitional difficulties increased gradually in severity and led to complete urinary retention the day before hospitalization. He was admitted with an inlying urethral catheter in place. Physical examination revealed a chronically ill-appearing male with multiple subcutaneous nodules. The prostate gland was normal in consistency and contour. The bulbocavernous reflex was absent; patchy saddle anesthesia was present. Cystometrography revealed a large bladder capacity with decreased exteroceptive and proprioceptive sensation; there were no uninhibited contractions, and the patient was unable to void. In view of the subcutaneous nodules and evidences of dysfunction of the sacral part of the spinal cord, a tentative diagnosis of neoplasm metastatic to skin and spinal cord was made. Endoscopy confirmed the examiner's suspicions by demonstrating no signs of obstructive uropathy. Subsequent studies disclosed bronchogenic carcinoma with extensive metastases to skin, bone, and the sacral part of the spinal cord.

CASE 2.—A 37-year-old male was admitted to the University Hospital with the complaint of intermittent low back pain present since 1944. Recently the pain had increased in severity and radiated down the right lower extremity. Physical examination was negative, except for moderate limitation of motion in the lumbosacral spine and an absent ankle jerk on the right. A diagnosis of ruptured nucleus pulposus was made, and it was decided to treat the patient conservatively with traction. On the morning of the second day of hospitalization, the patient complained of hesitancy and difficulty in urinating. Urologic consultation was requested, and examination revealed no abnormalities except for an absent bulbocavernous reflex. On the basis of this finding, myelograms were made immediately; these revealed a complete block at L-5 to S-1. An emergency laminectomy was performed, with the removal of the ruptured disk. Postoperatively the patient voided with ease. The bulbocavernous reflex response was normal within several days after operation. In this case the reflex was of utmost value in that it gave immediate objective evidence that the herniated disk was impairing the function of the sacral part of the spinal cord and was thus giving rise to urinary difficulties.

Summary

Bladder dysfunction is frequently the first sign of a lesion of the sacral part of the spinal cord. Every patient with difficulties in micturition should be examined for integrity of this part of the spinal cord. The Bors version of the bulbocavernous reflex has been found to be extremely valuable in determining abnormalities of the conus medullaris.

COUNCIL ON PHARMACY AND CHEMISTRY

Report to the Council

The Council has authorized publication of the following report from the Committee on Toxicology.

H. D. Kautz, M.D., *Secretary.*

The following report is a summary of the 1956 annual meeting of the Committee on Toxicology. These proceedings have been digested in order to bring to the medical profession timely reports on subjects that might not otherwise come to the readers' attention. Certain of the more important topics considered and actions taken thereon by the Committee are set forth.

Bernard E. Conley, *Secretary*
Committee on Toxicology.

ANNUAL MEETING OF THE COMMITTEE ON TOXICOLOGY

The Committee on Toxicology held its annual meeting on March 29, 1956, at the headquarters of the American Medical Association, Dr. Torald Sollmann, Chairman, presiding. In addition to the Chairman and Secretary, the following members were present: Drs. J. M. Arena, H. B. Haag, A. J. Lehman, E. Press, and Mr. J. C. Ward. In addition to headquarter's representatives, Drs. E. W. Constable, State Chemist, North Carolina; K. P. DuBois, Toxicity Laboratory, University of Chicago; and W. J. Hayes and S. W. Simmons, United States Public Health Service, attended as guests of the Committee.

Abstracted reports of some of the more important discussions and actions follow:

Kerosene Poisoning.—A subcommittee on poisoning by kerosene was appointed to study measures for improved safety in the use of petroleum distillates. Progress was reported on current projects to develop a monograph on kerosene poisoning and to promote precautionary labeling. Proposals for the clinical evaluation of various methods of treatment and laboratory investigation of methods for determining amounts of absorbed kerosene were discussed. The Committee agreed to join the American Academy of Pediatrics and the American Public Health Association in a joint clinical study of the treatment of poisoning by kerosene and petroleum distillate.

Exploitation of Nonprescription Drugs.—During the past year, several instances potentially harmful to the public health, especially that of children, have occurred. Representative situations include promotion of a clown-shaped medicine bottle designed to attract children to the container, promotion of vitamin pills on a children's program in a manner appealing to the toddler's tastes for sweets, and distribution of aspirin by vending machines. Since drugs cause 20% of the accidental deaths (33% in children under 5 years) and 22% of the suicides from nongaseous poisons, the Committee feels compelled to comment on these developments.

Devices intended to tempt children to accept drugs as something other than medication can have only unfortunate consequences. Medicine containers designed as toys tempt the very young to take freely of their contents. Vending machines for the automatic dispensings of aspirin, vitamins, and other nonprescription drugs are subject to the same censure. Such machines operate unattended, and children cannot be expected to discriminate between those that dispense gum and candy and those that dispense drugs. Accordingly, the Committee moved that it be placed on record as against the use of vending machines for drugs in public places accessible to children and others lacking in mature judgment.

Poison: Definition and List.—The Committee has been repeatedly asked to define and enumerate substances that it considers poisonous. To this end, definitions of poison presented in 11 current textbooks on pharmacology and medical jurisprudence submitted by 25 leading pharmacologists and representative legal definitions of 16 national and local government agencies in this country and abroad were collected and examined.

There is no uniformity of legal or scientific opinion as to what constitutes a poison. Various laws, both state and national, vary widely in their definitions. Statutes that employ dosage values vary in their specifications from 5 grains to 5 gm. as the "destructive," "deadly," or "fatal" quantity for "(adult) human life." Those state laws not utilizing a quantitative definition employ vague, indefinite, and generally unsatisfactory terms such as "noxious," "deleterious," or "virulent poisons" to specific chemicals classed as poisons.

Since a precise definition that would fit all circumstances is not possible, the Committee felt that any substance that, when improperly used, may produce harm by chemical action should be provided with an appropriate precautionary label statement. Such precautionary statements should provide warnings for different categories of hazards.

A list of several hundred poisonous substances compiled from legal and trade sources in this country and abroad is also under consideration for adoption.

Public Education About Poisons.—A report of a conference between a Committee representative and school health workers in Richmond, Va., was given regarding means for education of the public about poisons. The school health workers felt that a variety of approaches should be used, such as poster contests on chemical safety and distribution of pamphlets similar to those given away during Fire Prevention Week. They felt that the 30 million school children could be made watchdogs for chemical safety.

The value of radio and television programs presented in such form as to be appealing to both children and parents was stressed. Local chapters of the American Red Cross and the Parent-Teacher Associa-

PROGRESS REPORT OF AMERICAN DIABETES ASSOCIATION ON ORALLY EFFECTIVE HYPOGLYCEMIC SULFONYLUREAS

GUEST EDITORIAL

Arthur R. Colwell, M.D.
Dwight Ingle, Ph.D.
Maurice E. Krahl, Ph.D.
Rachmiel Levine, M.D.
and
Henry T. Ricketts, M.D.

Almost a year has elapsed since the beginning of the current revival of interest in the sulfonylureas as hypoglycemic agents. The first announcements, made in the German medical press in October, 1955,[1] were quickly relayed to other countries, including Canada and the United States. Intensive study is being conducted here and the sale of the drugs is being postponed pending substantial proof of safety in prolonged use, mechanisms of action, and clear indications for therapy. Two pharmaceutical firms are supplying their products, now known as carbutamide (BZ-55) and tolbutamide (Orinase, U-2043), to clinical investigators who are observing their action in many laboratories and in several thousand diabetic subjects.

Three conferences have been held during 1956 (two in Indianapolis and one in Kalamazoo) in which leading researchers in the United States and Canada have reported current data and debated their significance. Symposiums on the subject have been or will be published in current issues of several medical journals.[2] The intensity and caution with which the developmental work has been conducted here can well serve as a model for products of this nature. It is reminiscent of the care with which insulin itself was studied before general release. The evidence in support of current concepts concerning mechanisms of action and clinical use of these compounds cannot be reviewed in a brief editorial report such as this. Interested readers are referred to the mass of data already or soon to be reported.[2]

The compounds do not appear to increase utilization of glucose by the peripheral tissues. Early suggestions that the liver might be the major site of action have not received convincing support, although the output of glucose from the intact organ does seem to be reduced. With larger than therapeutic doses, thyroid hyperplasia results from chronic use of carbutamide in animals and radioiodine uptake is reduced in man, but these appear to be side-effects, as with thiourea compounds. There seem to be no measurable effects of the new drugs on anterior pituitary or adrenocortical function.

At present the best estimate as to the site of action points to the pancreas. The early German studies suggesting alpha-cell destruction with inhibition of glucagon production have not been confirmed. On the other hand, an effect dependent on the presence of beta cells is strongly suggested by almost uniform lack of response to the drugs in alloxanized subjects and those who have undergone total pancreatectomy and in "total" spontaneous diabetes, especially in juveniles. An effect on beta cells to cause release of insulin is indicated by studies on direct pancreatic perfusion, cross circulation, and islet size, but the fact that certain physiological actions of the compounds are unlike those of insulin casts some doubt upon this hypothesis. Insulin itself inhibits ketosis, enhances the peripheral utilization of glucose, increases the glycogen content of muscle, and raises the blood pyruvate level. At the moment it is not clear whether sulfonylurea action is accompanied by such criteria of insulin effects.[2c] Data of different investigators are conflicting on this point. This may be due to the manner by which the drugs affect insulin secretion, or possibly we are dealing with the release of hypoglycemic agents other than insulin.

Members, American Diabetes Association Informational Committee on Antidiabetic Compounds (Chairman, Dr. Colwell).

(*d*) Report of Third Lilly Conference on Carbutamide, *Indianapolis*, Sept. 13-14, 1956, Diabetes, to be published.

Therapeutically the compounds reduce hyperglycemia and glycosuria in many persons with mild and early diabetes. They are virtually ineffective in severe forms of the disorder where insulin-dependence is manifest. The diabetics likely to respond best are those who need insulin the least, as a rule. For this reason they may be the very same patients who should restrict food intake, lose weight, and conserve natural islet function, and not receive help from drugs. There are hints that beta-cell exhaustion may follow long-continued use of the drugs—an additional reason for the utmost caution in their wide application.

Toxic reactions to carbutamide seem to be on the order of those seen with other sulfonamide compounds. A recent survey shows severe hematological, hepatic, and generalized allergic reactions in about 2% of some 7,000 patients and milder side-effects, such as skin rashes and gastrointestinal symptoms, in an additional 3%.[2d] In another study the incidence of side-effects in 279 cases was about 9%.[2d] There have been a number of fatalities.[2d] No similar objective data are available yet on tolbutamide. Maintenance dosages of about 1 gm. daily and blood levels in the range of 10 to 15 mg. per 100 ml. appear to be effective and safe in most instances, but it must be borne in mind that allergic reactions may occur with much smaller amounts.

The usefulness of these drugs probably will be limited to those diabetics who do not really need insulin. In some cases these drugs will be useful, also, to those who refuse to take insulin, who are allergic to it, or who should not take it because of occupational hazards.

THE PHYSICIAN AND DISASTER

Recent natural disasters occurring in the United States and abroad once again serve as a reminder to the practicing physician of his responsibilities to the community, over and above the immediate care of his patients. After floods, hurricanes, tornadoes, fires, and lightning and vehicular accidents, the public, besieged with reports of what has been done to bring calm out of chaos, is rarely told how to prepare for similar future calamities. At an even later date, the medical journals come forth with preventive medical programs for the protection of food supplies, sanitation procedures, and evacuation techniques based on past experience, but mainly directed at the public health facilities of an area.

What of the private practitioner? Where does he find out what to do when the next disaster strikes? Nothing in the medical literature or in the wealth of civil defense material can make him part of a planned disaster service team while he is sitting in his office or making home and hospital calls. Also rare is the medical society whose disaster plan is so complete that members not only know their duties but have even had trial or practical examples.

Much of the so-called medical unpreparedness has been blamed on lethargy and disinterest, along with multitudes of other excuses. The situation is analogous to the disease that has many purported cures—no one really knows the answer. Today's community physician would gladly give of his time and effort if he only knew when, where, and how his particular services were actually needed. It cannot be called unusual that many a well-intentioned physician has voluntarily proceeded, or has been directed, to some disaster scene only to find the situation completely under control and half a dozen more of his colleagues standing around knowing they were not needed but unable to leave due to conceivable public reaction, or the remote possibility of their services being required at a later time.

What appears to be necessary in the event of most natural disasters is a type of medical aid program planned and sponsored by the local medical society. This should be based on a particular community's needs and fully coordinated with local health, police, and other disaster officials. As only one example, a society forms a panel of four or more physicians who would usually be available when the need arose. If and when medical aid is called for, the number-one physician on the roster will be contacted (or number two if the first cannot be reached) and escorted to the disaster scene. This physician then would assume the responsibility of requesting and securing additional selected medical personnel if actually required or alerting hospitals and other medical care facilities to have medical aid waiting for casualties to arrive. Much better care can be afforded patients where proper equipment exists and where no one hospital receives more than it can properly handle. An example of another type of program is given on page 985 of this issue.

Naturally there are many ways to obtain the same successful medical disaster plan, but it appears that to achieve any result the leadership must be in the hands of those who are actually to perform the service. Of course, cooperation between adjacent communities will have to be organized, but this should be secondary to taking care of one's own. Integrating a locally devised, practical disaster plan with state and national civil defense would perhaps be more workable than directing the medical profession "from above" without regard to cultural patterns and existing resources. A compendium of the best local ideas could then be adapted to a nationwide plan.

ORGANIZATION SECTION

REPORT OF JOINT COMMISSION ON ACCREDITATION OF HOSPITALS

The August, 1956, bulletin of the Joint Commission on Accreditation of Hospitals (660 N. Rush St., Chicago: Kenneth B. Babcock, M.D., director) is reproduced below for the information it contains that will be of interest to many physicians.—Ed.

A meeting of the Board of Commissioners of the Joint Commission on Accreditation of Hospitals was held on July 28, 1956 in Chicago. Raymond Peterson, M.D. was welcomed as a new Commissioner. Dr. Peterson represents the American Medical Association and was appointed to serve the unexpired term of the late Rolland J. Whitacre, M.D.

"Stover" Report

The Commissioners representing the American Medical Association presented the report of the Committee of the American Medical Association House of Delegates to Review the Functions of the Joint Commission on Accreditation of Hospitals. This report was approved by the House of Delegates in June, 1956.

CONCLUSIONS OF THE COMMITTEE

1. *Accreditation of hospitals should be continued.*
2. *The Joint Commission should maintain its present organizational representation.*
3. *The Board of Trustees should report annually to the House of Delegates on the activities of the Joint Commission.*
4. *Physicians should be on the administrative bodies of hospitals.*

The Board of Commissioners reviewed the report carefully and expressed on record that Wendell C. Stover, M.D., Chairman, and his committee had conducted an objective study of the functions of the Commission and that the report of their findings was judicious and statesmen-like.

Because we would like to share this excellent and important report with you, a copy is enclosed. It is complete except for a reproduction of the "Standards for Hospital Accreditation", the names of the Commissioners, and the corporate structure of the Commission which were included in the original report. The reference committee of the Council on Medical Education and Hospitals of the American Medical Association added a single recommendation urging the Commission to study "the problem of the exclusion from hospitals and arbitrary limitation of the hospital privileges of the general practitioner" and to seek methods whereby hospital privileges can be determined and granted "on the basis of professional qualifications and demonstrated ability."

In order to understand the actions of the Board of Commissioners, we urge that you read the "Stover" report first. We would also like to solicit your help in extending this information as widely as possible by sharing this Bulletin with your staff and associates.

ACTIONS OF THE BOARD OF COMMISSIONERS

1. Agreement.
2. Agreement.
3. No action by the Board of Commissioners indicated.
4. Very close liaison between the medical staff and the governing board of a hospital must be maintained. The method used to accomplish this should be determined locally.

   By way of explanation, the Commissioners think that the composition of the governing board of a hospital should be determined at the local level and that the Commission should not specifically state whether physicians should or should not be members. From its inception, the Commission through its publications has stated that in accredited hospitals close liaison between the medical staff and the governing board is essential. To assure good quality patient care, good working relationships are vital. However, the selection of the most effective way to accomplish this goal in the individual hospital can best be determined locally.

   We call your attention to the recommendations made in June, 1953 by the Joint Committee of the Boards of Trustees of the American Medical Association and the American Hospital Association on Hospital-Physician Relationships. We quote as follows—

   > "The general purpose of hospitals and physicians is to aid each other in the delivery of the best possible medical care to patients. To attain such a purpose requires full cooperation among medical staffs, governing boards and administrative heads of hospitals. One important method of attaining this objective is that duly designated representatives of the medical staff shall have full and direct access to the governing board with due consideration to the position of the administrator as chief executive officer of the hospital. The various methods by which the medical staff may have access to the hospital governing board follow. These methods are not listed in the order of their desirability, and there may be other acceptable liaison plans developed depending upon local conditions.

a. The executive committee of the medical staff and a committee of the governing board with the hospital administrator can serve as a joint committee.

b. Representatives of the medical staff can serve as members of the medical staff committee of the governing board with the hospital administrator.

c. Representatives elected by the medical staff can attend meetings of the hospital governing board.

d. Members of the medical staff can be members of the hospital governing board."

To repeat, the Standards for Hospital Accreditation state that the "governing body . . . should . . . establish a formal means of liaison with the medical staff preferably by a joint conference committee" (a or b above); however any one or combination of the above methods that prove effective are acceptable.

5. *General practice sections in hospitals should be encouraged.*	5. The present policy of the Commission with respect to general practice sections should be continued, that the decision as to the establishment of a general practice department should be made by the local medical staff.
6. *Staff meetings required by the Joint Commission are acceptable, but attendance requirements should be set up locally and not by the Commission.*	6. Referred to a committee for study; a report and recommendations to be submitted at the next meeting of the Board of Commissioners to be held in December, 1956. Since this Conclusion constitutes a change in the Standards, the established procedure for changing standards was followed. In April, 1954, the Commissioners voted that the following procedure for changing the Standards for Hospital Accreditation be adopted: "Any proposal for a change, addition or deletion in the Standards for Hospital Accreditation of the Joint Commission on Accreditation of Hospitals shall be presented and discussed at a regular meeting of the Board of Commissioners. A committee shall then be appointed to submit recommendations at the next regular meeting of the Board of Commissioners. If agreement to the proposed change is unanimous among those present and voting, the proposal will be adopted. If there is one or more dissenting votes, action will be deferred until the next meeting of the Board, at which time a majority vote will be decisive."
7. *The Joint Commission should not concern itself with the number of hospital staffs to which a physician may belong.*	7. The Standards for Hospital Accreditation do not restrict multiple staff appointments.
8. *The Joint Commission is not and should not be punitive.*	8. Agreement.
9. *The Joint Commission should publicize the method of appeal to hospitals that fail to receive accreditation.*	9. In the event a hospital is not accredited following a survey, the process of appeal will be explained in the letter notifying the hospital that it has not been accredited. The original Bylaws of the Joint Commission on Accreditation of Hospitals in Article III, Section 8 provide for such hearings. A copy of the Bylaws was distributed with the first issue of the Bulletin of the Commission in November, 1952.
10. *Reports on surveys should be sent to both administrator and chief of staff of hospitals.*	10. Copies of the covering letter and recommendations sent to the administrator following a survey will also be sent to the chief or president of the medical staff and the president of the governing board.
11. *Surveyors should be directly employed and supervised by the Joint Commission.*	11. There is no objection in principle that surveyors could be directly employed and supervised by the Commission. Whether or not this is done is a decision for each member organization of the Commission to make.
12. *Surveyors should work with both administrator and staff.*	12. Agreement.
13. *New surveyors should receive better indoctrination.*	13. The orientation program for surveyors is being steadily strengthened.
14. *Blue Cross and other associations should be requested not to suspend full benefits to nonaccredited hospitals until those so requesting have been inspected.*	14. Pertains to individual Blue Cross Plans and cannot be acted upon by the Joint Commission on Accreditation of Hospitals.
15. *The American Medical Association should conduct an educational campaign for doctors relative to the functions and operations of the Joint Commission.*	15. No action.

16. *The Committee also suggests that the American Medical Association and the American Hospital Association encourage educational meetings for hospital boards of trustees and administrators either on a state or national level to acquaint these bodies with the functions of accreditation.*

17. *This Committee asks to be discharged upon submission of this report to the House of Delegates.*

16. No action.
Although it is inappropriate for the Commission to take action on Conclusions 15 and 16, the Commission will actively support the member organizations in accomplishing these objectives.

17. No action.

Change in Published List of Accredited Hospitals

In publishing the annual list of accredited hospitals, the practice has been to separate the fully accredited and provisionally accredited hospitals. These designations have been used for many years and the attitude has developed that provisional accreditation implies a secondary type of accreditation. This attitude is incorrect. The Commission has interpreted provisional accreditation to mean that a hospital meets the Standards for Accreditation to a degree that recognition should be given and that the potentialities for full accreditation exist. To avoid perpetuating a misunderstanding, hospitals will now be accredited for one year or for three years. In the annual published list no distinction will be made between hospitals accredited for three years and those accredited for one year.

Except for the publication of the annual list, there are no other changes in policy or administrative procedure. Accreditation for three years applies to those hospitals now fully accredited and accreditation for one year applies to those now provisionally accredited. Following a survey, the hospital will be informed of the period of time for which it is accredited. Those accredited for one year will be visited the following year. If on the second successive survey the hospital is again accredited for one year, it will be notified that following the third survey it must have improved patient care to warrant three year accreditation or be reduced to non-accreditation.

Certificates of Accreditation will be issued only to those hospitals accredited for three years.

Accreditation of Psychiatric Hospitals

The Board of Commissioners considered the program of accreditation of psychiatric hospitals. Daniel Blain, M.D., Medical Director, American Psychiatric Association, and Raymond W. Waggoner, M.D., Member, Central Inspection Board of the American Psychiatric Association, were invited to participate in the discussion. It was decided that a committee of the Board of Commissioners would request a meeting with representatives of the American Psychiatric Association to discuss the program further and submit a report at the next meeting of the Board of Commissioners.

PUBLICATIONS ON INDUSTRIAL HEALTH AVAILABLE

The Council on Industrial Health, American Medical Association, 535 N. Dearborn St., Chicago 10, announces the availability of two publications. "Absence from Work Due to Non-Occupational Illness and Injury" has been taken from the proceedings of the session on work absence of the Annual Congress on Industrial Health held in January, 1956. The publication is the work of the Committee on Medical Care for Industrial Workers, a joint committee of the Council on Industrial Health and the Council on Medical Service of the American Medical Association. It contains the statements of 22 representatives of the medical profession, management, and labor who participated in panel discussions entitled: "Where Are We?" "What Are We Doing?" "What Can We Do?" and "How Can We Make Better Use of Records?" Single copies are available without charge from the Committee on Medical Care for Industrial Workers. Additional copies are 50 cents each through the Order Department of the American Medical Association.

"Guiding Principles of Medical Examinations in Industry" has been reprinted from THE JOURNAL, July 7, 1956. Single copies will be furnished without charge by the Council on Industrial Health. Requests for multiple copies should be addressed to the Order Department, American Medical Association. Purchase orders or checks with orders will facilitate handling. The price scale is as follows: 2 to 25 copies, 6 cents each; 26 to 50 copies, 5½ cents each; 51 to 100 copies, 5 cents each; 101 to 200 copies, 4½ cents each; additional hundreds up to 1,000, $4.40 per hundred; and additional thousands, $44 per thousand.

FIRST FILM IN "MEDICINE AND THE LAW" SERIES

The role of the medical expert witness is the theme of the first of a film series on medicine and the law being produced by the Wm. S. Merrell Company of Cincinnati in cooperation with the American Medical Association and the American Bar Association. Entitled "The Medical Witness," this 30-minute film illustrates what doctors should and should not do when testifying in court. Its primary purpose is to teach doctors and lawyers how to present cases requiring expert medical testimony thoroughly and accurately so that a just decision can be made. C. Joseph Stetler, Director of the A. M. A. Law Department, stated that the need for educating doctors in courtroom technique is borne out by the fact that between 60 and 85% of all court cases involve medical testimony and require physicians as witnesses. The Law Department is assisting in the supervision of the filming of the series. This motion picture will be premiered Tuesday, Nov. 27, at the A. M. A. Clinical Session in Seattle. Prints will be available for showings at state and county medical society meetings through the A. M. A. Film Library after Dec. 15.

COUNCIL ON MEDICAL SERVICE

A STUDY OF MATERNAL MORTALITY COMMITTEES

This is part 4 of a series of articles by the Committee on Maternal and Child Care of the Council on Medical Service reviewing the organization and operation of maternal mortality study committees. The purpose of this specific study is to obtain information that may be utilized in the preparation of guides and, in turn, may be helpful in the development and operation of maternal mortality committees in other areas of the United States. The descriptive material to follow is concerned with the Maternal Welfare Committee of the Illinois State Medical Society.

Downstate Illinois Maternal Mortality Study

History.—The Maternal Welfare Committee of the Illinois State Medical Society is a long-established committee that has continuously promoted improvements in maternity care. Some of its early work included publication of pamphlets, such as "Advice to Expectant Mothers" and "What Price Abortions?" which were distributed widely by the committee under the seal of the Illinois State Medical Society. In addition to these early efforts toward improving lay education, the committee, in cooperation with the Illinois Department of Public Health and the departments of obstetrics and gynecology of the University of Illinois and the other medical colleges, participated in postgraduate professional education for improving maternity care throughout the state. The educational program consisted of lectures to county medical societies by speakers from the various universities and from the committee. A visual education program was developed at the University of Illinois to which its department of obstetrics and gynecology contributed space and facilities and the part-time services of its department personnel. This program involved the annual production of an exhibit to be shown first as a part of the scientific exhibit of the state medical society and secondly at the annual meeting of the American Medical Association. The exhibits were then returned to the university for use in undergraduate and postgraduate teaching.

The exhibits were demonstrated personally throughout the meetings by the professor of obstetrics, who was thus available for consultation to physicians attending the meetings. The exhibits were photographed, and lantern slides were made for use in undergraduate teaching at the university and in county medical society meetings. Twenty-four such exhibits have been produced, covering practically all phases of obstetrics. Photographs of the exhibit material, mounted on five 3-by-5-ft. panels, have been circulated to hospitals in the downstate area for study by physicians, nurses, and house staffs. Refresher courses were offered at the university during the summer months, and lectures were given by members of the four university medical schools as well as clinical demonstrations by the staff of the University of Illinois.

One of the valued programs in Illinois, developed by the Illinois Department of Public Health with the assistance of the department of obstetrics and gynecology of the University of Illinois and approved by the Illinois State Medical Society and the U. S. Children's Bureau, has been the inspection and licensing of hospitals. All hospitals giving maternity service are required by statute to be licensed and must comply with the regulations that were initially established by the passage of the Maternity Hospital Licensing Act of June 24, 1915. In the latest revision of this act, on July 1, 1953, the required regulations became a part of a General Hospital Licensing Act, administered by the Bureau of Hospitals. Among the requirements are acceptable records; for example, each hospital must submit to the Bureau of Hospitals a monthly report that shows the number of mothers and infants cared for, the types of delivery, operative procedures employed, the incidence and types of complications encountered, the frequency of abortions and ectopic gestation, and the number and causes of stillbirths and neonatal and maternal deaths. All hospitals at the end of each year are sent copies of their cumulative individual tabulations with those of their birth group and the entire state average. Much information of interest to the obstetric specialty is found in these statistical reports, and many hospitals make use of these data in their staff discussions and medical audit.

As early as 1937, the Maternal Welfare Committee recommended to the state medical society the appointment of county maternal and child health committees to study all maternal, infant, and fetal deaths occurring in their counties. In 1947, a program was prepared by the Division of Maternal and Child Health of the state health department and presented to the Maternal Welfare Committee and to the council of the state medical society. This program called for a thorough analysis of each death associated with gestation occurring in the hospitals outside of Chicago; it was approved by the committee and the state society and went into operation in January, 1948. (This maternal death study was exclusive of Chicago, where the subcommittee on maternal mortality of the Joint Maternal Welfare Committee of Cook County has been actively engaged in such a study since 1938.) Although improvements had been made in the maternal death rate in Illinois prior to 1948, information concerning maternal deaths was limited to that given on death certificates. It was believed that greater progress could be made in maternal care by differentiating each maternal death as to obstetric and nonobstetric causes; through a thorough appraisal of prenatal care; and by a determination of sequence of symptoms, thoroughness of laboratory studies, adequacy of consultation, correctness of diagnosis, method of treatment, autopsy findings, and questions of preventability and responsibility. The objective, then, of this joint project was to broaden knowledge of factors responsible for deaths associated with gestation, to effect a reduction of those factors, and, thereby, to effect a lower rate of maternal mortality and morbidity in Illinois.

Members.—The Maternal Welfare Committee is composed of a member and an alternate from each of the 11 councilor districts in Illinois. Appointments are made annually by the society president upon the recommendation of the councilor of each district and the chairman of the committee. The consultant in maternity and the chief of the Bureau of Maternal and Child Health are ex officio members. Two visiting obstetricians have been appointed by the committee to investigate each maternal death occurring in Illinois (exclusive of Chicago). The chairman of the committee is appointed by the president of the state medical society, and a vice-chairman is chosen by the chairman.

Scope of Study.—All deaths in Illinois (exclusive of Chicago) associated with pregnancy and three months post partum are studied by this committee. The three-month postpartum period is specified because the first three years of the study indicated no deaths over three months post partum that were classified as maternal (obstetric) by the committee. However, any death definitely related to or caused by a previous pregnancy is included in the study. A death is classified as maternal (obstetric) if it is due to such causes as hemorrhage, toxemia, and infection (puerperal, abortion, or ectopic) or to such other causes as embolism, anesthesia, shock, acute heart failure resulting from improper management of the patient, cerebral hemorrhage coincident with the delivery, and incompatible blood as well as other causes related directly to the pregnancy, delivery, or postpartum complications. Nonmaternal (nonobstetric) deaths are those that the committee feels are not related to the pregnancy, such as appendicitis; auto accidents; brain abscesses; burns; cancer; such infections as encephalitis, poliomyelitis, and pneumonia; and those that are due primarily to a preexisting disease, such as rheumatic heart disease or kidney disease. At times the committee finds it difficult to classify a death as either maternal or nonmaternal because of some preexisting disease that might not have caused the death of the pregnant woman or resulted in postpartum complications had conditions and treatment been ideal. In such cases, judgment on the part of the committee members is the deciding factor in the classification. Deaths of nonresidents are studied in the same manner and charged to the place of occurrence. They are not included in the final maternal mortality rate based on residence for that particular year but are reallocated to their state. Isolated studies of neonatal deaths in certain counties have been conducted by the chairman and certain members of the committee but have not been on a continuing basis (except in Chicago).

Operation: Agencies and Personnel Involved.—The maternal mortality study in downstate Illinois is a joint project of the Bureau of Maternal and Child Health of the state department of public health and the Maternal Welfare Committee of the state medical society. The department of public health shares the major expense in the study; it pays the travel expense of the obstetrician-investigator plus $25 per case investigated. It also handles all clerical, stenographic, and secretarial work, in addition to providing an office secretary and office space for the project. The state medical society pays the expense, including travel expense, of the committee meetings. In addition, the health department pays for the autopsy, performed by a member of the Illinois Pathological Society, if such services are otherwise not available to the attending physician.

The Bureau of Maternal and Child Health has had three sources from which to obtain information. First, a "Report of Maternal Death Form" is supplied each hospital in the state (exclusive of Chicago). The bureau requests that each hospital send this completed report to the department of public health immediately after any death associated with pregnancy (including abortion and extrauterine gestation), whether the patient died in the obstetric division or in any other department of the hospital. This report form identifies the patient and the hospital and gives the date of death; age at death; gravidity details; period of gestation; whether the death occurred before, during, or after labor; and whether it was an operative delivery. It requests information on the autopsy, primary and contributing causes of the death, and the name of the attending physician. On receipt of this report form, the office secretary for the committee's maternal death study forwards this information to the obstetrician-investigator for his follow-up.

In the event that the hospital fails to send the department of public health this special report on a maternal death, it is discovered in the monthly report previously mentioned, which, by law, must be submitted to the Bureau of Hospitals. Maternal deaths in this monthly report are checked against those special report forms that the Bureau of Maternal and Child Health is supposed to receive immediately after each maternal death. As a third check, to make sure that all maternal deaths are discovered, the bureau screens monthly all the death certificates of women of child-bearing age. If a death appears to be related in some way to a pregnancy, whether or not pregnancy was mentioned on a death certificate, the case is checked.

After the obstetrician-investigator receives the data on the death, he visits the physician who attended the patient and the hospital in which the death occurred. This visit is usually at least a month after the death, to assure that the hospital chart will have been completed and that pathological reports and all other pertinent data about the case will be available. After the inauguration of the study in 1948, a consultant in maternity (a board-certified specialist in obstetrics and gynecology and emeritus associate professor, University of Illinois) to the Illinois Department of Public Health performed this investigative task. However, during the last two years, this work has been performed by two privately practicing specialists in obstetrics and gynecology appointed by the committee. The obstetrician-investigator makes every effort to talk with the attending physician and obtain complete details on the case from him. The six-page detailed questionnaire requires a careful check of the hospital records. Occasionally it is necessary to consult with other hospital personnel and the family; this is done at the discretion of the attending physician. After completion of his study, the obstetrician-investigator makes an abstract of the case and distributes a copy to each member of the Maternal Welfare Committee prior to its meeting. All physicians and hospitals in the state are aware of the study, and, therefore, the obstetrician-investigator encounters little opposition in his quest for information on maternal deaths. The Maternal Welfare Committee, through its members in each councilor district, publicizes the activities of the committee at county society meetings and to hospital staffs, thereby laying the groundwork for a good working relationship.

All protocols of death studies that the committee members use are anonymous. Physician, patient, and hospital names do not appear; this information is known only to the obstetrician-investigator and the secretary at the Bureau of Maternal and Child Health. The full Maternal Welfare Committee meets four times a year and devotes a full day (usually a Sunday) to an audit of the protocols previously sent to the members by the Bureau of Maternal and Child Health. Although any interested physician may attend a committee meeting on request, it is not common that one does. If a regular member does not attend a meeting, he is responsible for getting his alternate to attend. At each meeting, during which an average of 20 protocols are reviewed, the chairman calls on each member to present a case. Even though the members have all had the protocols for study prior to the meeting, the case abstract is read completely. If the obstetrician-investigator, who is always present at the meetings, has further information than that which is contained in the protocol, he presents it. He also presents his impression of the hospital, as to its facilities and services, in the particular case under review. Discussion follows, and the committee decides the apparent cause of death, whether it was a maternal or a nonmaternal death, and whether it was preventable (based upon the ideal). If it is not clearly a case of unquestionable preventability, it is classified as a case with preventable factors or as not preventable. If it is classified as a case with preventable factors, such factors are listed. In the case either of a preventable death or of a death with preventable factors, the responsibility for that death is assigned to the physician, the patient, the hospital, or any combination of these. Special note is made as to whether the cause as determined by the committee is the same as that which appeared on the death certificate. A list is compiled of those procedures or specific techniques that might have been used to better advantage than those that were used by the attending physician.

After each meeting a form letter is sent from the Bureau of Maternal and Child Health to each attending physician who had a case that was discussed at the meeting. He is informed that his case was presented and asked if he wishes to have the findings and recommendations of the committee sent to him. He is given the case number and asked to write to the chairman for this information. On the physician's request, a letter is written to him pointing out the findings of the committee and their recommendations in cases similar to it. The physician is also invited to attend the next meeting of the committee to further discuss the case.

Follow-Up.—If the attending physician does not specifically indicate through written request or through the obstetrician-investigator that he desires the findings of the committee after discussion of the case, there is no other way for him to be apprised of the committee's decision in his particular case. No other person in the hospital or on the obstetric staff is given any information as to the committee's findings.

The first three-year report of maternal mortality in downstate Illinois, for the period 1948-1950, was read before the Section on Obstetrics and Gynecology at the 100th Annual Meeting of the American Medical Association in Atlantic City, N. J., June 15, 1951, and published in THE JOURNAL.[1] A four-year report was made in the *American Journal of Obstetrics and Gynecology* in 1952.[2] Also, a report of the maternal mortality study in Illinois was presented before the American Public Health Association, Maternal and Child Health Section, at the 80th annual meeting in Cleveland, Ohio, Oct. 23, 1952.

Each year the Maternal Welfare Committee submits to the Illinois State Medical Society its annual report. Results of the study, too, are used in the teaching of obstetrics and gynecology at the University of Illinois and at the University of Chicago Medical School. This material, however, is kept anonymous, so that there will be no possible connection between the case presented and the physician, hospital, or patient concerned. The Maternal Welfare Committee has had exhibits at the annual meetings of the state medical society and has stimulated interest among the obstetricians and general practitioners interested in obstetrics in the American congresses, which are sponsored by the American Committee on Maternal Welfare and held every three years.

Another service that the Maternal Welfare Committee provides in cooperation with the Illinois Department of Public Health is the furnishing of exhibits to hospitals in the state. This program of exhibiting in hospitals is a perpetual one—one exhibit in a strategic place in the hospital for two or three weeks during the year alternating with other exhibits at various times of the year, in order that each hospital in the state will have had an opportunity for its staff to become acquainted with the various complications of pregnancy and how to meet those complications. Twelve exhibits presently in use in Illinois are as follows: (1) Pregnancy in the Bicornuate Uterus, (2) Breech Presentation, (3) Uterine Carcinoma, (4) Cesarean Section, (5) Destructive Operations, (6) Ectopic Pregnancies, (7) Forceps Delivery, (8) Hemorrhage in Pregnancy, (9) Motherhood, (10) Puerperal Sepsis, (11) Toxemias of Pregnancy, and (12) Abortion. As a part of the committee's educational program, an annual report on the activities of the committee is made to the state obstetric and gynecologic society. Further presentations are anticipated for various publications.

Results: Statistical Analysis.—Prior to the inauguration of the study of maternal deaths in Illinois, a statistical study of maternal mortality in Illinois hospitals for the period 1943-1947 indicated that the mortality in 1943 was 2.07 per 1,000 live births. This was reduced to 0.98 [illegible] 000 live births by 1947.

made annually by the society president upon the recommendation of the councilor of each district and the chairman of the committee. The consultant in maternity and the chief of the Bureau of Maternal and Child Health are ex officio members. Two visiting obstetricians have been appointed by the committee to investigate each maternal death occurring in Illinois (exclusive of Chicago). The chairman of the committee is appointed by the president of the state medical society, and a vice-chairman is chosen by the chairman.

Scope of Study.—All deaths in Illinois (exclusive of Chicago) associated with pregnancy and three months post partum are studied by this committee. The three-month postpartum period is specified because the first three years of the study indicated no deaths over three months post partum that were classified as maternal (obstetric) by the committee. However, any death definitely related to or caused by a previous pregnancy is included in the study. A death is classified as maternal (obstetric) if it is due to such causes as hemorrhage, toxemia, and infection (puerperal, abortion, or ectopic) or to such other causes as embolism, anesthesia, shock, acute heart failure resulting from improper management of the patient, cerebral hemorrhage coincident with the delivery, and incompatible blood as well as other causes related directly to the pregnancy, delivery, or postpartum complications. Nonmaternal (nonobstetric) deaths are those that the committee feels are not related to the pregnancy, such as appendicitis; auto accidents; brain abscesses; burns; cancer; such infections as encephalitis, poliomyelitis, and pneumonia; and those that are due primarily to a preexisting disease, such as rheumatic heart disease or kidney disease. At times the committee finds it difficult to classify a death as either maternal or nonmaternal because of some preexisting disease that might not have caused the death of the pregnant woman or resulted in postpartum complications had conditions and treatment been ideal. In such cases, judgment on the part of the committee members is the deciding factor in the classification. Deaths of nonresidents are studied in the same manner and charged to the place of occurrence. They are not included in the final maternal mortality rate based on residence for that particular year but are reallocated to their state. Isolated studies of neonatal deaths in certain counties have been conducted by the chairman and certain members of the committee but have not been on a continuing basis (except in Chicago).

Operation: Agencies and Personnel Involved.—The maternal mortality study in downstate Illinois is a joint project of the Bureau of Maternal and Child Health of the state department of public health and the Maternal Welfare Committee of the state medical society. The department of public health shares the major expense in the study; it pays the travel expense of the obstetrician-investigator plus $25 per case investigated. It also handles all clerical, stenographic, and secretarial work, in addition to providing an office secretary and office space for the project. The state medical society pays the expense, including travel expense, of the committee meetings. In addition, the health department pays for the autopsy, performed by a member of the Illinois Pathological Society, if such services are otherwise not available to the attending physician.

The Bureau of Maternal and Child Health has had three sources from which to obtain information. First, a "Report of Maternal Death Form" is supplied each hospital in the state (exclusive of Chicago). The bureau requests that each hospital send this completed report to the department of public health immediately after any death associated with pregnancy (including abortion and extrauterine gestation), whether the patient died in the obstetric division or in any other department of the hospital. This report form identifies the patient and the hospital and gives the date of death; age at death; gravidity details; period of gestation; whether the death occurred before, during, or after labor; and whether it was an operative delivery. It requests information on the autopsy, primary and contributing causes of the death, and the name of the attending physician. On receipt of this report form, the office secretary for the committee's maternal death study forwards this information to the obstetrician-investigator for his follow-up.

In the event that the hospital fails to send the department of public health this special report on a maternal death, it is discovered in the monthly report previously mentioned, which, by law, must be submitted to the Bureau of Hospitals. Maternal deaths in this monthly report are checked against those special report forms that the Bureau of Maternal and Child Health is supposed to receive immediately after each maternal death. As a third check, to make sure that all maternal deaths are discovered, the bureau screens monthly all the death certificates of women of childbearing age. If a death appears to be related in some way to a pregnancy, whether or not pregnancy was mentioned on a death certificate, the case is checked.

After the obstetrician-investigator receives the data on the death, he visits the physician who attended the patient and the hospital in which the death occurred. This visit is usually at least a month after the death, to assure that the hospital chart will have been completed and that pathological reports and all other pertinent data about the case will be available. After the inauguration of the study in 1948, a consultant in maternity (a board-certified specialist in obstetrics and gynecology and emeritus associate professor, University of Illinois) to the Illinois Department of Public Health performed this investigative task. However, during the last two years, this work has been performed by two privately practicing specialists in obstetrics and gynecology appointed by the committee. The obstetrician-investigator makes every effort to talk with the attending physician and obtain complete details on the case from him. The six-page detailed questionnaire requires a careful check of the hospital records. Occasionally it is necessary to consult with other hospital personnel and the family; this is done at the discretion of the attending physician. After completion of his study, the obstetrician-investigator makes an abstract and professional education, the committee is currently active in developing the Illinois Committee on Maternal Welfare, an integral part of the American Committee on Maternal Welfare. Through such an organization, the education and cooperation of physicians, public health personnel, nurses, hospital administrators, anesthetists, nutritionists, and other groups, including lay organizations, will be achieved and will materially help in the primary objective of reducing mortality and morbidity in mothers and newborn infants.

The committee believes that the profession must be continually on the alert, in order that gains already made will not be lost and that further reduction in mortality and morbidity in Illinois can be made. The committee further believes that more widespread and earnest establishment of such study programs as it has conducted in downstate Illinois and the search for other avenues of approach taught by the findings of such a study will lead to a definite saving of lives of mothers and newborn infants.

Neurologic Eye Disease.—The human eye is actually a portion of the central nervous system. As the embryo grows a portion of the brain becomes more or less separated and comes to lie on the surface of the organism. This delicate and most important special sense organ is exposed to the environment and all of its accompanying dangers. . . . A number of diseases that affect the nervous system also affect the eye. Multiple sclerosis is one of the best examples. Other disorders of the brain, such as tumors, affect the eye in an indirect manner, resulting from the fact that the visual pathways may become secondarily involved. . . . The fact that the eye is often involved in this manner is of great help to the neurologist and the neurosurgeon in detecting the presence and locating the position of disorders of the brain. Many brain tumors first manifest themselves by alterations of vision in one or both eyes, and by careful study of such alterations it is often possible to locate the trouble accurately and at times to predict the exact type of difficulty. . . . Pituitary tumors are one of the most frequent neurologic conditions producing loss of vision. This results from the close proximity of the pituitary gland to the optic chiasm or crossing point of the two optic nerves. Loss of vision is usually the first and only symptom of these tumors. . . . Tumors at any place in the brain are likely to obstruct the flow of the cerebrospinal fluid. When this occurs the pressure builds up in the brain, producing the characteristic headache symptoms. In some manner this pressure is transmitted by way of the optic nerves and produces a swelling in the nerve heads known as "choked disks." In the early stages this swelling or choking of the disk causes no visual difficulty and is of importance only as an indication to the examiner of trouble in the brain. . . . The usual "stroke," when it affects the vision, blacks out a half of the patient's visual field. This occurs because the condition involves one side of the brain and, just as it may paralyze the opposite side of the body, it may likewise affect the opposite side of the patient's vision. This loss of vision is referred to as "homonymous hemianopsia"; that is, one half of each eye is blinded. . . . When a "stroke" results from basilar artery disease, the patient may be completely blind or so nearly blind that he has no useful vision. A number of the patients will have warning of impending trouble in that they experience transient blacking out of their vision along with other transient neurologic troubles.—T. P. Kearns, M.D., Diagnosis and Treatment of Neurologic Eye Disease, *The Sight-Saving Review*, Summer, 1956.

COUNCIL ON NATIONAL DEFENSE

Local Medical Disaster Preparedness

The disaster committee of the Alameda–Contra Costa County Medical Association of California prepared, with the assistance of the local civil defense offices, "Disaster Planning for Medical Services" and published it in April, 1956. The following report is based on the concepts of that local medical plan. It was prepared as a summary of their disaster planning with the cooperation of the Oakland office of Civil Defense and Disaster.

The Council on National Defense of the American Medical Association believes this report will be of interest to local medical societies and perhaps it may encourage them to prepare their own medical disaster plans, if they do not already have one.

Frank W. Barton, *Secretary.*

ORGANIZED MEDICINE AND CIVIL DISASTER

Wayne P. Chesbro, M.D., Berkeley, Calif.

The need for medical and health services disaster planning for the care of civilian populations became apparent during World War II when reports of the devastation wrought by explosive missiles in Britain and Germany were received. The magnitude of destruction of life and property was something never before envisioned. As was expected, civil disaster planning and services were developed to a high degree of efficiency in the countries affected by such destructive weapons. With the closing of World War II on the ominous note of the total destruction wrought by nuclear weapons, together with the growing conviction that geographical location was no longer a protection against nuclear warfare, the need for civil disaster planning, whether for "survival" in an all-out nuclear war or for the adequate medical care of casualties in a large-scale local disaster, was recognized by most state and county civil defense administrators.

Noting the meager personnel that carried on civil disaster planning for medical and health services in California and throughout the United States, and cognizant of the need for participation of organized medicine in such planning, the disaster committee of the Alameda–Contra Costa Medical Association began the initial study and planning for the activities of the medical and health services in order to offer to the local civil disaster departments the guidance, resources, and support of a local, organized medical association composed of a group of some 1,500 physicians serving an estimated population of one million in the two East Bay counties, a target area.

Chairman, Alameda–Contra Costa Medical Association Disaster Committee.

The association in committee discussion developed the concept that for efficient civil disaster planning, state medical associations down to the county level should assume direct responsibility for the plans of the medical and health services division. It is our firm conviction that, if physicians are to be called upon to serve in any disaster, their state and local medical organizations, with the concurrence of the state civil defense disaster offices, should designate the procedures they are to follow. It was also recognized that, in order to spark the interest of the medical group and to keep the activity alive, the planning must not be too detailed or involved and, most emphatically, should be geared first to the real potentialities of local disasters. For purposes of definite committee action, initial disaster planning was divided into three phases; in order of importance, hospital disaster planning, large-scale local disaster planning, and total disaster planning.

Hospital Disaster Planning

A medical association disaster committee should present to all hospital disaster committee chairmen a prototype hospital disaster plan. (Our association used the disaster plan of the Providence Hospital, Oakland, Calif.). A hospital disaster plan should encompass three divisions.

Division 1.—There should be hospital disaster planning for disaster within the hospital, such as that occurring from fire, explosion, earthquake, radiological contamination, or epidemic.

Division 2.—The hospital disaster plan should include planning for a large-scale local disaster occurring within the community or area in which the hospital is resident and in which the facilities of the hospital remain functional.

Division 3.—Hospital disaster planning should include a program for total disaster in which the hospital must undergo evacuation to and reconstitution of personnel and materials in a peripheral area and still function to its greatest capability in accepting the casualty load thrust upon its meager resources and surviving personnel.

Hospital disaster planning, at best, will proceed slowly, and committee members should be chosen for their patience and perseverance, for they will have much need for both. A copy of the Providence Hospital disaster plan is available to anyone interested in using it as a reference in developing workable plans for his own hospital.

Large-Scale Local Disaster Planning

For purposes of complete coverage of disaster within Alameda and Contra Costa counties, the two counties are divided into five operational areas. Reference to figure 1 will explain the jurisdictional areas as existent in the planning of the association. All areas have a chief of medical and health services with alternates in sufficient numbers to "cover" the duty at all times. In the event of a disaster within the area, the designated chief immediately becomes the medical officer in charge. He represents the president of the medical association at the disaster site. First-aid care, casualty evacuation to area hospitals, requests for additional medical and nursing personnel, mobile aid teams, and supplies all originate with the area chief of the medical and health services.

Reference to figure 2 shows the basic concept of the function of the area chief, medical and health services, in the disaster area. The function of the medical association disaster committee, at the association headquarters, will be to fill the requests of the area chief and to coordinate all other area facilities for mutual support. In the event of a large-scale local disaster involving more than one area, over-all authority should be directed from the medical association headquarters by the president or his designate, the chairman of the disaster committee. All physicians appointed within the areas as chiefs or alternates should be members of the medical association. In large-scale local disaster planning, there should be complete integration of the medical and health services plans with the existing civil disaster coordinators, Red Cross, and armed forces available to serve in disasters, the area hospitals, the physician assigned to disaster stations, the allied medical professions, and the local industry disaster planning.

Existing Civil Disaster Coordinators, Red Cross, and Armed Forces.—In order that all levels may function to mutual aid and support, orientation of command physicians (area chiefs, alternates, disaster committee members) should begin at the area level and extend from local civil disaster departments through regional jurisdictions to state headquarters. All concerned should be cognizant of existing civil disaster supplies and familiar with designated civil defense emergency hospitals and aid stations. Information should be available covering liaison facilities, established by mutual agreement, of the Red Cross and the armed forces of the immediate and adjacent areas and air transport service (especially helicopter) available in large-scale local disaster. Our association has, through the facilities of the U. S. Coast Guard, conducted an aerial survey of all the major hospitals of the two counties. U. S. Coast Guard helicopter service is now available in emergency cases authenticated by the association's disaster committee.

Area Hospitals.—The area chief of the medical and health services and his alternates should schedule regular meetings with their respective hospital administrators and disaster committee chairmen so that mutual planning will be kept current and well integrated. Hospital administrators should have available at all times a daily census of patients, with special reference to the numbers who can be moved or become ambulatory in order to permit rapid bed expansion in event of disaster. A census of the medical and technical personnel of the hospital on a 24-hour basis should be available. There should be provision for supplies necessary to continue operation of the hospital with an additional 75% increase in patient load for a 24-hour period.

Physician Assignments to Disaster Stations.—All assignments of physicians to disaster stations should be made by the disaster committee of the medical association. All hospitals should be asked to submit the names of the staff members who are to be considered as essential to the function of the hospital during an emergency. In the assignments of physicians, duplication of highly specialized skills should be avoided if possible. All physicians should be assigned to a hospital staff as a primary assignment for large-scale local disaster. Mobile medical teams and supplies should emigrate from the hospital to the scene of the disaster upon request of the area medical chief.

Allied Medical Professions.—A census should be made of the allied medical professions (nursing, dentistry, pharmacy, veterinary medicine, optometry, chiropody) and the technical services (laboratory and x-ray technicians, physiotherapists, dietitians) in each area. Assignments should be made from these groups to the area hospitals with the understanding that their function would be to serve as an auxiliary staff under the regular staff of the hospital in the event of a large-scale local disaster. Provision should be made for the indoctrination of this personnel, and their duties in the hospital or aid station should be delineated. Short courses should be given members of the dental and veterinary medical professions covering their roles as physicians' assistants. Definite hospital disaster assignments will maintain the interest of members of these allied medical professions in disaster planning.

Fig. 2.—Organization applicable to each of the five disaster areas of Alameda-Contra Costa counties in a local disaster. No medical personnel will move into a disaster area unless requested by that area's medical chief or alternate at the disaster site. The area medical chief or alternate is in full command of all medical services in the area in which the disaster occurs. Helicopter service for medical use may be ordered only by the area chief or alternate. Such an order must be transmitted directly to the chairman of the disaster committee at association headquarters. In event of disaster in Alameda or Contra Costa County, a mobile communications unit from the Oakland civil defense is immediately attached to the headquarters for direct communication with the medical chief or alternate on the disaster site.

Local Industry in Disaster Planning.—Industry should be represented in civil disaster planning both at area and association headquarters levels. Since, in many instances, major catastrophes have their origin

This program has category 1 (formal) approval by the American Academy of General Practice. A luncheon will be held at 12:30 p. m. and a cocktail party from 5-6 p. m. A special program, including a fashion show, has been arranged for wives.

PENNSYLVANIA

Meeting on Industrial Health.—The 21st annual meeting of the Industrial Hygiene Foundation will be held at the Mellon Institute, Pittsburgh, Nov. 14-15. The Medical Conference Wednesday morning will include papers on pulmonary physiology as related to industrial chest diseases, effective educational techniques in health counseling, and legal aspects of industrial medical practice. The Legal Conference the same morning will be concerned with the medical and legal aspects of health problems incident to the industrial use of atomic energy. Pneumonoconiosis and occupational carcinogens will be considered at the Chemical-Toxicological Conference. The Joint Technical Conference Wednesday afternoon will bring together all the groups for a panel discussion on "Health Problems Involved in the Manufacture, Sale, and Use of Toxic Materials." Panelists will include a representative of management, an industrial physician, a lawyer, an engineer, an industrial toxicologist, and an insurance executive. Joseph C. Hinsey, Ph.D., director of the New York Hospital-Cornell Medical Center, New York, will discuss future industrial medical problems at the Management Conference on Thursday. Other topics to be considered include the health problems involved in automation, the importance of epidemiology in determining whether a health problem actually exists, new channels of communication between management and technical personnel in matters of industrial health, management's views on industrial health problems, and systematic attention to health in operations research.

Philadelphia

Institute for Care of Cardiac Child.—An Institute for the Care of the Cardiac Child will be held at Children's Heart Hospital of Philadelphia, Nov. 7, to acquaint members of the medical, nursing, and social service professions with developments pertaining to young patients with heart disease. A tour of the spital will precede discussions on the recognition and treatment of congenital heart disease, the active stage of rheumatic fever, and rheumatic valvular disease. Afternoon sessions (2-4 p. m.) will consider other aspects of the subject. The luncheon speaker will be Dr. Hugh Montgomery, associate professor of medicine, University of Pennsylvania School of Medicine, and chief of the vascular section, University of Pennsylvania Hospital. The chairman of the institute is Dr. George D. Geckeler. The institute will be sponsored by the Children's Heart Hospital; Heart Association of Southeastern Pennsylvania; Department of Public Health, City of Philadelphia; School District of Philadelphia; Pennsylvania Heart Association; Department of Health, Commonwealth of Pennsylvania; Philadelphia County Medical Society; and the Hospital Council of Philadelphia.

TEXAS

Blackford Memorial Lecture.—The Grayson County Medical Society announces the first annual Blackford Memorial Lectureship on cancer at the Hotel Denison, Denison, Nov. 13, 1-5 p. m., in symposium form. Dr. Randolph L. Clark Jr., Houston, will monitor the program. The Blackford Memorial Fund, set up by Mrs. Clara Smith of Denison and Houston in honor of her father, who was a pioneer Denison banker, was established with the aim of having eminent authorities on cancer and cancer research as principal speakers and to keep the physicians of the area up-to-date on the latest progress in the field of cancer.

WISCONSIN

Pathologists Meeting.—The Wisconsin Society of Pathologists will hold its fall meeting at the Columbia Hospital Auditorium, 3321 N. Maryland Ave., Milwaukee, Nov. 12, 1:30 p. m. (sponsored by the Milwaukee County Chapter, American Cancer Society). The subject of the meeting will be "Collagen Diseases and Related Conditions." Dr. Milton G. Bohrod, pathologist and director of laboratories, Rochester General Hospital, Rochester, N. Y., will serve as moderator. Cocktails at 5:30 p. m. will precede dinner, 6:30 p. m., at the University Club, 924 E. Wells St., Milwaukee. Dr. John Z. Bowers, dean, University of Wisconsin Medical School, Madison, will speak on "Changing Concepts in the Teaching of the Basic Sciences."

GENERAL

Meeting of Teachers of Preventive Medicine.—The 13th annual meeting of the Association of Teachers of Preventive Medicine will be held in Atlantic City, N. J., Nov. 11. The first session at the Hotel Ambassador, 9 a. m., will include the following round tables:

Clinical Preventive Medicine, Glen R. Leymaster, Salt Lake City, chairman.
Epidemiology, John P. Fox, New Orleans, chairman.
Medical Care, Milton Terris, Buffalo, chairman.
Occupational Medicine, Jean S. Felton, Oklahoma City, chairman.
Public Health, Ray E. Trussell, New York, chairman.
Rehabilitation, Rodney R. Beard, San Francisco, chairman
Statistics, George F. Badger, Cleveland, chairman.

Dr. Duncan W. Clark, Brooklyn, N. Y., president, will preside over the second session at the Ritz Carlton Hotel, 2-5 p. m., when a panel will be presented on "Family Study and Care in Medical Education." Participants will include Dr. E. M. Holmes Jr., Richmond, Va.; Dr. John P. Hubbard, Philadelphia; Dr. John H. Kennell, Cleveland; J. Garth Johnson, Ph.D., Albany, N. Y.; Dr. George G. Reader, New York; and Dr. Robert E. Shank, St. Louis. At the dinner session, 6:30 p. m., Dr. Leona Baumgartner, New York, will speak on "Experiences in India" and Dr. John R. Paul, New Haven, Conn., will discuss "Experiences in the Soviet Union."

Electrical Techniques in Medicine and Biology.—The ninth annual Conference on Electrical Techniques in Medicine and Biology, sponsored by the American Institute of Electrical Engineers, the Institute of Radio Engineers, and the Instrument Society of America, will be held at the Governor Clinton Hotel, New York City, Nov. 7-9. A panel discussion on "Instrumentation for Cardiology," under the chairmanship of Dr. Lee B. Lusted, Bethesda, Md., will be presented Wednesday morning. Papers will include "A Cathode-Ray Cardiograph" and "High Voltage Condenser Discharge as a Means of Cardiac Resuscitation in Ventricular Fibrillation." The afternoon session will include a panel on "Methods and Standards for Measurement of Electron Beams," with Dr. John Laughlin, New York, as chairman. "The Philosophy Underlying Radiation Protection" will be presented that evening by Lauriston S. Taylor, Ph.D., chief, division of atomic and radiation physics of the National Bureau of Standards, Washington, D. C. A field trip to Brookhaven National Laboratory, Upton, Long Island, N. Y., is scheduled for Thursday. Friday morning a panel discussion will be concerned with "Design of Instruments for Research in Artificial Respiration." Papers to be delivered during the afternoon session on instrumentation in medicine and biology will include "Artificial Respiration Control" and "A New Type of Electroencephalograph Wave Analyser."

Annual Military Surgeons Convention.—The 63rd annual convention of the Association of Military Surgeons will be held at the Statler Hotel, Washington, D. C., Nov. 12-14. The theme of the meeting will be "The Expanding Horizons of Military Medicine." The presidential address will be delivered Monday, 9:15 a. m., by Rear Adm. Winfred P. Dana, M.C., U. S. Navy, assistant chief for aviation and operational medicine and research and medical military specialties, bureau of medicine and surgery, Department of the Navy, Washington, D. C. Detlev W. Bronk, Ph.D., president, National Academy of Sciences, Washington, D. C., will be the guest speaker at the morning session. An international luncheon will be held Tuesday, 1:30 p. m.; Adm. Arthur W. Radford, U. S. Navy, chairman, Joint Chiefs of Staff, Washington, D. C., will be the guest speaker. Meeting on Tuesday will be the dental, veterinary, sanitary engineering, and medical specialist sections. The latter section, meeting at 3 p. m., will include discussion of "Medical Research Today" by Dr. Stuart M. Sessoms, assistant director, Clinical Center, National Institutes of Health, Bethesda, Md., and a panel on "Medical Research in Total Research Hospital Setting and Its Impact on the Nutrition, Physical Therapy, and Occupational Therapy Services," with Dr. John L. Fahey, general medicine branch, National Cancer Institute, Bethesda, Md., as a participant. The sustaining membership and nursing sections will meet on Wednesday.

Meeting of Inhalation Therapists.—The annual meeting and lecture series of the American Association of Inhalation Therapists will be held at the Park Sheraton Hotel, New York, Nov. 12-16. Physicians will make the following presentations:

Pressure Breathing, Peter A. Theodos, Philadelphia.
Inhalation Therapy in Controlling Diseases of the Chest, Edwin R. Levine, Chicago.
Resuscitation: Including the Cardiac Arrest Problem, Virginia Apgar, New York.
Physiologic Basis of Inhalation Therapy, Alvan L. Barach, New York.
Aerosol Therapy, Hylan A. Bickerman, New York.
Bronchial Drainage: Including Exsufflation, Gustav J. Beck, New York.
Inhalation Therapy in Acute Obstructive Diseases, Albert H. Andrews Jr., Chicago.
Bronchiolitis and Pneumonia in Infants and Children, Milton I. Levine, New York.
Inhalation Therapy in the Treatment of Smoke, Gas, and Fume Poisoning, Maurice S. Segal, Boston.
Oxygen Therapy and Prevention of Retrolental Fibroplasia, Charles U. Letourneau, Chicago.
Qualifications for Inhalation Therapists, Edwin Emma, New York.
Tent Therapy, Alvis E. Greer, Houston, Texas.
Organizing an Inhalation Therapy Department, Gordon M. Wyant, Saskatoon, Saskatchewan, Canada.

Field trips have been arranged to the headquarters of the emergency service division of the New York City Police Department, Tuesday, 7:30 p. m., and to the Presbyterian Medical Center, Wednesday, 7:30 p. m. At 12:30 p. m. Friday, Drs. Greer, Wyant, and Vincent J. Collins, New York, will participate in a panel entitled "Selling the Hospital Administrator on an Inhalation Therapy Department."

Chest Physicians Meeting.—The Potomac and Southern chapters of the American College of Chest Physicians will hold a joint meeting at the Shoreham Hotel, Washington, D. C., Nov. 11-12. Single-author presentations will include:

Pulmonary and Metabolic Aspects of Cystic Fibrosis (Mucoviscidosis), Paul A. di Sant'Agnese, New York.
Current Status of the Pneumonias, Robert C. Austrian, New York.
Pathogenesis and Treatment of Peripheral Vascular Collapse Associated with Fulminant Diffuse Pulmonary Infiltrations, Donald W. Seldin, Dallas, Texas.
Application of Hypothermia in the Correction of Cardiovascular Lesions, Major Edward J. Jahnke Jr., Washington, D. C.
Severe Crushing Injuries of the Chest: A New Method of Treatment, Edward E. Avery, Chicago.
Features and Significance of Hypertrophic Osteoarthropathy, James F. Hammarsten, Oklahoma City.
Ten Years of Tuberculosis Surgery, J. Maxwell Chamberlain, New York.
Controversial Aspects of the Surgery of Tuberculosis, James D. Murphy, Baltimore.

At 12 noon Sunday, Dr. William F. Miller, Dallas, Texas, will serve as moderator for a panel entitled "Physiologic Therapy of Bronchopulmonary Disease," for which the participants will be Drs. Alvan L. Barach, New York, and Maurice S. Segal, Boston. Drs. Otto C. Brantigan and Ross L. McLean, Baltimore, and Sol Katz, Washington, D. C., will participate in an x-ray conference at 4 p. m., moderated by Dr. Charles N. Davidson, Baltimore. A cocktail party at 6 p. m. (courtesy of the Potomac chapter) will precede the banquet ($6.50, including gratuity and tax). The third Paul Turner Memorial Lecture (sponsored by the Southern chapter) will be presented at 8:15 p. m. by Dr. O. Theron Clagett, Rochester, Minn., who will discuss "Carcinoma of the Lung."

Southern Medical Association.—The golden anniversary meeting of the Southern Medical Association will be held at the Sheraton-Park Hotel, Washington, D. C., Nov. 12-15 (30 hours credit, American Academy of General Practice). The program Monday will be opened by Dr. Ralph M. Caulk, president, Medical Society of the District of Columbia, and will include 15 presentations by Washington physicians, in addition to a panel discussion entitled "Preoperative Evaluation and Choice of Anesthesia in Surgical Patients with Reduction of Circulatory Reserve," Dr. William E. Bageant, Washington, D. C., moderator. The first general session at the Mayflower Hotel, Monday, 8 p. m., will include the presidential address by Dr. W. Raymond McKenzie, Baltimore, and presentation of the Certificate of Meritorious Service to Dr. Margaret M. Nicholson, Washington, D. C., and the John Benjamin Nichols award to Mr. Joseph H. Himes, Washington, D. C. At the second general session Wednesday, 8 p. m., Dr. David B. Allman, Atlantic City, N. J., President-Elect, American Medical Association, will deliver an address entitled "Who Will Carry the Torch?" A Geriatrics Symposium will be held Thursday, 9 a. m. at the Sheraton, with Dr. Milford O. Rouse, Dallas, Texas, as moderator. More than 300 papers will be presented during the assembly, which includes 20 section meetings. Twenty motion pictures will be shown Tuesday, Wednesday, and Thursday. The Southern Flying Physicians will hold a luncheon and scientific program Tuesday at the Mayflower Hotel. The preliminary program lists 19 medical schools that will hold alumni and fraternity reunions during the meeting. The annual golf tournament will be held at the Kenwood Golf and Country Club, Bethesda, Md., Monday.

Association of American Medical Colleges.—The 67th annual meeting of the Association of American Medical Colleges will be held at the Broadmoor Hotel, Colorado Springs, Colo., Nov. 12-14. Preconference meetings of the standing committees will be held on Sunday, Nov. 11. Copies of the annual reports of these committees will be presented to each person as he registers, and open hearings on them will be held at 4:00 p. m. on Monday. Dr. Robert A. Moore, president of the association, will present his address on Monday, 9:30 a. m. At the annual dinner Monday evening, the Borden award will be presented and Adolph W. Schmidt, president of the A. W. Mellon Educational and Charitable Trust, will present an address. On Monday and Tuesday afternoons, 2:00 p. m., the general subject for discussion will be "Experiments in Medical Education," for which a number of speakers have been assigned special topics. On Wednesday, 9:00 a. m., Drs. John Z. Bowers and Robert C. Parkin, Madison, Wis., will discuss "A 'Twenty-Eight Year' Experiment in Preceptorial Medical Education"; Horace A. Page, Ph.D., Madison, Wis., "Description of a Study Designed to Evaluate Preceptorial Experience and Its Relation to the Plans, Skills and Attitudes of Senior Medical Students"; Drs. Henry J. Bakst and William Malamud, Boston, "Combined Teaching in Human Ecology"; Dr. Eugene A. Hargrove, Chapel Hill, N. C., "An Introduction to Clinical Medicine in the First Year"; and Granger Westberg, Chicago, "Religious Aspects of Medical Teaching." Some 15 papers will be read by title. A program of activities for the ladies has been arranged. For details of short tours in the mountains and elsewhere consult with Miss Allyn at the registration desk.

Gerontological Society Meeting.—The ninth annual scientific meeting of the Gerontological Society will be held at the Hotel Hamilton, Chicago, Nov. 8-10 under the presidency of Dr. William B. Kountz, St. Louis. The general session Thursday, under the chairmanship of Dr. Emmet B. Bay, Chicago, will consist of a panel on Progress in Gerontology and will include presentation of "Progress in Social Work and Administration" by Mrs. Elizabeth Breckinridge, Chicago; "Progress in the Biological Sciences" by Dr. George E. Wakerlin, Chicago; and "Progress in the Psychological and Social Sciences" by Ward C. Halstead, Ph.D., Chicago. The sections on biological sciences, clinical medicine, psychological and social sciences, and social work and administration will hold simultaneous meetings, Thursday, 2-4:30 p. m.; Friday and Saturday, 9:30-12 noon. The section on clinical medicine will present a clinic at Passavent Memorial Hospital, Friday, and the meeting Saturday will include a symposium moderated by Dr. Thomas H. McGavack of New York. The Friday session of the section on psychological and social sciences will consist of a symposium entitled "Assessment of Mental Health in the Elderly," under the chairmanship of Dr. Ewald Busse, Durham, N. C. The Thursday meeting of the section on social work and administration will consist of a panel on "Senile Patients and Their Care," and the Friday session will include a panel on "Adult Boarding Homes and Their Place in Community Resources for Older People." "Planning Education and Recreation Programs for Older People" will be the title of the social work section panel on Saturday. The evening session Thursday, 8 p. m., includes an illustrated lecture "Aging in the Atomic Age." The general session Friday, 2-5 p. m., will consist of a symposium on "Education for Maturity," moderated by Dr. Edward J. Stieglitz, Washington, D. C. Cocktails at 6 p. m. will

DEATHS

Davidoff, Eugene ⊕ Schenectady, N. Y.; born in New York City May 11, 1901; State University of Iowa College of Medicine, Iowa City, Iowa, 1927; associate professor of psychiatry at Albany (N. Y.) Medical College; at one time on the faculty of the Syracuse (N. Y.) University College of Medicine, specialist certified by the American Board of Psychiatry and Neurology; member of the American Psychiatric Association and the American Psychopathological Association; associated briefly with Willard (N. Y.) State Hospital before becoming clinical director at Craig Colony, Sonyea, in 1943; during World War II joined the armed forces as a lieutenant colonel and finally served in this capacity as chief neuropsychiatrist for the Veterans Administration at Watervliet; at one time in charge of the mental hygiene clinic at Syracuse (N. Y.) Psychopathic Hospital; child psychiatrist of Ellis Hospital; joint author with Elinor S. Noetzel of a book entitled "The Child Guidance Approach to Juvenile Delinquency"; died while vacationing at Cape Cod, Mass., July 23, aged 55, of a heart attack.

Falconer, Ernest Henry ⊕ San Francisco; born in Pardeeville, Wis., May 19, 1883; McGill University Faculty of Medicine, Montreal, Quebec, Canada, 1911; clinical professor of medicine emeritus at the University of California School of Medicine, where in 1921 he became chief of the blood clinic, which he had established; fellow and long governor for Northern California of the American College of Physicians, appointed to its board of regents in 1947 and made first vice-president in 1950; during World War I was with Base Hospital 30, the University of California Unit, in France; specialist certified by the American Board of Internal Medicine; consultant in hematology, Franklin Hospital and Children's Hospital; visiting physician at the University of California Hospital; on May 27, 1953, the McGill University in Montreal, Quebec, Canada, conferred on him an honorary LL.D degree; died in Los Gatos, Aug. 11, aged 73.

Spitz, Sophie ⊕ New York City; born in Nashville, Tenn., Feb. 4, 1910; Vanderbilt University School of Medicine, Nashville, Tenn., 1932; specialist certified by the American Board of Pathology; member of the American Association of Pathologists and Bacteriologists and the American Society of Clinical Pathologists, assistant professor of pathology at the Sloan-Kettering division of Cornell University Medical College; formerly assistant medical examiner of New York City; during World War II was with the Army Institute of Pathology, now the Armed Forces Institute of Pathology; joint author of "Pathology of Tropical Diseases", director of the pathology department, New York Infirmary for Women and Children; assistant attending pathologist at Memorial Center for Cancer and Allied Diseases, where she died Aug. 10, aged 46, of recurrent carcinoma of the colon.

Harney, Charles Harrison, Sewickley, Pa.; born in Lexington, Ky., July 11, 1900; Columbia University College of Physicians and Surgeons, New York City, 1929; member of the Tennessee State Medical Association; certified by the National Board of Medical Examiners; specialist certified by the American Board of Surgery; fellow of the American College of Surgeons; veteran of World Wars I and II; retired from the Veterans Administration Sept. 30, 1953; formerly chief of the surgical service of the Veterans Administration Hospital in Mountain Home, Tenn., served on the staffs of the Bryn Mawr (Pa.) Hospital and the Pennsylvania and Jefferson Medical College hospitals in Philadelphia; died July 6, aged 55, of coronary thrombosis.

Rabil, Pierre Jamil, Washington, D. C.; born Oct. 25, 1912, University of Montreal Faculty of Medicine, Montreal, Quebec, Canada, 1938; served on the faculty of his alma mater and McGill University in Montreal, Quebec, Canada, where he was on the staff of the Hopital Ste. Jeanne d'Arc; assistant professor of surgery at Georgetown University School of Medicine; a lieutenant colonel in World War II, served with the Army in the European Theater and was awarded the Bronze Star, the Purple Heart, and the French Legion of Honor and Croix de Guerre; on the staff of the Georgetown University Hospital, where he died July 23, aged 43.

Akin, William Edwin, Jr., Paintsville, Ky.; University of Louisville School of Medicine, Louisville, 1931; fellow of the American College of Surgeons; veteran of World War II; past-president of the Johnson County Medical Society; an associate member of the American Medical Association; died in the Veterans Administration Hospital, Louisville, Aug. 2, aged 54, of cerebral thrombosis and femoral artery occlusion.

Ayers, Thomas Fred ⊕ San Francisco; University of California School of Medicine, San Francisco, 1920; served an internship and residency at Santa Clara County Hospital in San Jose; died June 21, aged 69, of hypertension and arteriosclerotic heart disease.

Baker, William Pope, Atlanta, Ga.; Emory University School of Medicine, Emory University, 1920; an associate member of the American Medical Association; fellow of the American College of Physicians; died July 11, aged 62.

Barber, Ira Zelna, Princeton, Ky.; University of Louisville Medical Department, Louisville, 1905; served as city and county physician; died June 17, aged 78.

Barshak, Max ⊕ New York City; University and Bellevue Hospital Medical College, New York City, 1915; died aboard the Grace Liner Santa Clara, Aug. 6, aged 67, en route to Venezuela.

Bell, Firman Merrill, Grant, Neb.; Central Medical College of St. Joseph, Mo., 1904; an associate member of the American Medical Association; for many years county physician; served as president of the Garden-Keith-Perkins Counties Medical Society; on the staff of the Perkins County Community Hospital; died Aug. 4, aged 83, of carcinoma of the colon.

Bourne, Ulysses Grant, Sr., Frederick, Md.; Leonard Medical School, Raleigh, N. C., 1902; an associate member of the American Medical Association; died in the Frederick Memorial Hospital July 15, aged 82, of cerebral hemorrhage.

Breen, Adrian Louis, Farley, Iowa; L.R.C.P., London, and M.R.C.S., of England, 1894; served in France during World War I; for many years a member and for one year president of the school board; formerly assistant superintendent of the Independence (Iowa) State Hospital; died in the Xavier Hospital, Dubuque, July 16, aged 83, of cancer.

⊕ Indicates Member of the American Medical Association.

Breslin, William Aloysius ⊕ Shenandoah, Pa.; Jefferson Medical College of Philadelphia, 1916; veteran of World War I; served in the regular U. S. Navy; past-president of the Shenandoah Medical Society; died July 18, aged 63, of cor pulmonale and congestive heart disease.

Bromund, Emile Herman, Oberlin, Ohio; Jenner Medical College, Chicago, 1905; died May 12, aged 84, of nephrosclerosis and arteriosclerosis.

Campbell, Isaac Augustus, Los Angeles; Kansas City (Mo.) Medical College, 1905; at one time health and quarantine officer for the United States at the Mexican port of Vera Cruz; died in the California Lutheran Hospital, July 30, aged 77, of carcinoma of the stomach.

Carmichael, Marvin Monroe, Osage, Okla.; Mississippi Medical College, Meridian, 1911; at one time associated with the Indian Service; died July 21, aged 70.

Coffield, Franklin Carver, Salem, Ky.; Hospital College of Medicine, Louisville, 1904; member of the Kentucky State Medical Association; died in Paducah July 10, aged 80.

Cook, Thomas Wood, Allentown, Pa.; University of Pennsylvania School of Medicine, Philadelphia, 1912; an associate member of the American Medical Association; fellow of the American College of Surgeons; on the staff of the Graduate Hospital of the University of Pennsylvania, Philadelphia, and the Sacred Heart Hospital; died July 29, aged 70, of coronary occlusion.

Cowie, Helen Jean, Redwood City, Calif.; Woman's Medical College of Pennsylvania, Philadelphia, 1906; died July 15, aged 81, of arteriosclerosis.

Cummings, Arthur Hibbard, Mesa, Ariz.; University of Buffalo School of Medicine, Buffalo, 1922; member of the Medical Society of the State of New York; an associate member of the American Medical Association; for many years district health officer for the New York State Health Department; during World War II served with the U. S. Public Health Service; served as director of the city health department of Portmouth, Va.; died Aug. 22, aged 60.

Davis, Elijah Gillam, Champaign, Ill.; St. Louis College of Physicians and Surgeons, 1891; died in the Carle Memorial Hospital, Urbana, July 26, aged 87, of cerebral vascular accident.

Davis, Robert I. ⊕ Birch Tree, Mo.; University of Louisville (Ky.) Medical Department, 1909; died July 2, aged 85.

DeLay, Eli Milton, Sulphur, Okla.; Bennett Medical College, Chicago, 1915; veteran of World War I; died July 21, aged 62, of carcinoma of the stomach with metastases.

Disbrow, G. Ward ⊕ Owensboro, Ky.; University of Maryland School of Medicine, Baltimore, 1913; specialist certified by the American Board of Radiology; member of the American College of Radiology; past-president and secretary of the Daviess County Medical Society; veteran of World War I; served on the Medical Milk Commission in New Jersey, and was a member of the Summit, N. J., Board of Health; on the staff of the Owensboro-Daviess County Hospital, where he died July 22, aged 66.

Druckerman, Leonard James ⊕ New York City; Cornell University Medical College, New York City, 1931; specialist certified by the American Board of Surgery; associate attending surgeon at the Mount Sinai Hospital; fellow of the American College of Surgeons; died July 30, aged 49, of acute coronary thrombosis.

Eastman, Henry Allen, Jamestown, N. Y.; University of Buffalo School of Medicine, Buffalo, 1892; died Aug. 26, aged 88.

Enniss, Joseph, Waynesboro, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1899; an associate member of the American Medical Association; died June 28, aged 81, of hypertension and cerebral hemorrhage.

Felker, Gertrude ⊕ Dayton, Ohio; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1901; named "the 1954 Woman of the Year" by the Dayton Business and Professional Women's Club; said to be the first woman physician to practice in Dayton; a determined pioneer in promoting the public health of her community, starting with a safe milk campaign long before the days of pasteurization; died July 22, aged 83, of coronary occlusion.

Finkelberg, Ivan Lewis ⊕ San Bernardino, Calif.; Loyola University School of Medicine, Chicago, 1916; member of the American Urological Association; died July 18, aged 65.

Fitzpatrick, Joseph W., Anchorage, Ky.; Hospital College of Medicine, Louisville, 1900; died July 25, aged 81.

Fox, Norman Albright ⊕ Greensboro, N. C.; University of Pennsylvania School of Medicine, Philadelphia, 1924; veteran of World Wars I and II; on the staffs of the Moses H. Cone Memorial Hospital, Wesley Long Hospital, and the Piedmont Memorial Hospital; died in the Wesley Long Hospital July 17, aged 56, of coronary thrombosis.

François, Silvain Joseph Alexander ⊕ New Glarus, Wis.; Marquette University School of Medicine, Milwaukee, 1916; on the staff of St. Clare Hospital in Monroe; died July 23, aged 65, of coronary thrombosis.

Giffen, John R. ⊕ Bangor, Mich.; Willamette University Medical Department, Salem, Ore., 1894; for many years served on the school board; died in South Haven July 24, aged 85.

Greenberg, Morris ⊕ Forest Hills, N. Y.; New York Homeopathic Medical College and Flower Hospital, New York City, 1924; served on the faculty of his alma mater; member of the New York Academy of Sciences; formerly on the staffs of the Queens General Hospital and the Triboro Hospital of Queens Hospital Center in Jamaica; died in the Oneida (N. Y.) City Hospital Aug. 3, aged 67, of acute cerebral hemorrhage.

Hale, Douglas McCardell, Coldspring, Texas; Tulane University School of Medicine, New Orleans, 1926; member of the State Medical Association of Texas; died July 18, aged 54, of coronary occlusion.

Harvey, James Rufus ⊕ Footville, Wis.; Milwaukee Medical College, Milwaukee, 1910; member of the American Academy of General Practice; past-president of the Rock County Medical Society; veteran of World War I; on the staff of the Mercy Hospital in Janesville; a director and president of the Footville State Bank; died in Janesville July 19, aged 74, of chronic lymphatic leukemia.

Hintze, Anne Augusta, Reading, Mass.; Woman's Medical College of Pennsylvania, Philadelphia, 1903; died April 8, aged 92, of coronary thrombosis and arteriosclerosis.

Hollingsworth, Albert A. ⊕ Indianapolis; Medical College of Indiana, Indianapolis, 1905; on the staffs of St. Vincent's and Methodist hospitals; died July 22, aged 76, of cancer.

Holt, Russell Devereaux ⊕ Staunton, Va.; Medical College of Virginia, Richmond, 1899; for many years associated with the Indian Service; died July 26, aged 86, probably of ventricular fibrillation and arteriosclerotic cardiovascular disease.

Hoshino, Mitsuharu ⊕ Honolulu, Hawaii; University of Texas School of Medicine, Galveston, 1920; president of the staff of the Kuakini Hospital, where he was honorary life member; a life member of Queen's Hospital; died in St. Francis Hospital May 29, aged 59, of cerebral hemorrhage.

Kapp, Henry ⊕ Haverhill, Mass; Tufts College Medical School, Boston, 1911; specialist certified by the American Board of Otolaryngology; member of the American Academy of Ophthalmology and Otolaryngology; veteran of World War I; chairman of the board of trustees of the Haverhill Municipal Hospitals (Hale); on the staff of the Haverhill Municipal Hospitals; died July 24, aged 66, of carcinoma of the lung.

Kelley, Edward Joseph, Watertown, Mass.; Tufts College Medical School, Boston, 1913; served on the teaching staff of his alma mater; for six years on the board of health, two of them as chairman; for many years associate medical examiner for the seventh Middlesex district and school physician; served on the staffs of the Mount Auburn Hospital in Cambridge and the Waltham (Mass.) Hospital; died July 24, aged 67, of carcinoma of the throat and pneumonia.

Kirkup, Norman Nelson, Detroit; University of Toronto Faculty of Medicine, Toronto, Ontario, Canada, 1919; died July 17, aged 62.

Krombein, Walter Henry ⊕ Buffalo; University of Buffalo School of Medicine, Buffalo, 1924; assistant professor of medicine at his alma mater; specialist certified by the American Board of Internal

Medicine; fellow of the American College of Physicians; consultant in internal medicine to the U. S. Public Health Service; on the staffs of St. Francis Hospital and the Buffalo General Hospital, where he died July 24, aged 55.

Langhoff, Arthur Harry ⊕ Mankato, Minn.; University of Minnesota Medical School, Minneapolis, 1922; died June 20, aged 66.

Liles, Nelson Pickett, Bastrop, La.; Medical College of South Carolina, Charleston, 1911; for many years director of the Morehouse health unit; died July 24, aged 71, of Parkinson's disease.

Lowry, James Cage, Dallas, Texas; Louisiana State University School of Medicine, New Orleans, 1955; intern, Methodist Hospital; died in Mineral Wells June 16, aged 26, in a private aircraft accident.

Mangan, Edward McDonnell, Forest Hills, N. Y.; Columbia University College of Physicians and Surgeons, New York City, 1947; member of the American Trudeau Society; served on the staffs of the Triboro Hospital of Queens Hospital Center and the Mary Immaculate Hospital in Jamaica; died April 1, aged 32.

Martin, James William ⊕ Omaha; Creighton University School of Medicine, Omaha, 1921; professor of orthopedic surgery at his alma mater; specialist certified by the American Board of Orthopaedic Surgery; member of the Clinical Orthopaedic Society and the American Academy of Orthopaedic Surgeons; fellow of the American College of Surgeons; for many years on the staff of Creighton Memorial St. Joseph's Hospital; died in Rochester. Minn., July 20, aged 60, of pulmonary edema and coronary sclerosis.

Meredith, Harold Hamilton ⊕ Oakland, Calif.; Gross Medical College, Denver, 1899; on the staff of Peralta Hospital; died Aug. 6, aged 77, of coronary sclerosis.

Metcalfe, Brice Fields, Greenville, Ohio; Medical College of Ohio, Cincinnati, 1899; served as secretary of the Darke County Medical Society; associated with the Wayne Hospital; died Aug. 3, aged 82, of arteriosclerosis.

Minor, Samuel West, Hinton, Okla.; University of Tennessee Medical Department, Nashville, 1905; an associate member of [illegible]e American Medical Association; died July 4, aged 84, of purulent urinary cystitis.

Morrill, Walter LeRoy, Sterling, Neb.; Omaha Medical College. Omaha, 1895; served on the staff of St. Elizabeth Hospital in Lincoln; died in Lincoln July 27, aged 83, of arteriosclerosis.

Moss, Daniel B., Palmyra, Mo.; Missouri Medical College, St. Louis, 1896; retired Sept. 15, 1938, as chief medical officer of the Chicago, Burlington and Quincy Railroad; at one time secretary of the American Association of Railway Surgeons; died July 21, aged 84.

Mowry, Harry Dale ⊕ Ambridge, Pa.; Jefferson Medical College of Philadelphia, 1926; on the staff of the Sewickley Valley Hospital in Sewickley; died in Monroeville July 24, aged 54, of acute hemorrhagic pancreatitis and coronary artery insufficiency.

Nevarez Izurieta, Miguel Angel ⊕ McAllen, Texas; Universidad Nacional Facultad de Medicina, Mexico, D. F., 1928; died near Armstrong April 15, aged 51, in an automobile accident.

Resmer, Norbert Joseph, Pittsburgh; Western Pennsylvania Medical College, Pittsburgh, 1902; an associate member of the American Medical Association; served as health examiner for the Mount Oliver (Pa.) School District; member of the staff of St. Joseph's Hospital and Dispensary, where he died July 7, aged 77, of carcinoma of the stomach.

Roberts, Buford Benjamin ⊕ Hawthorne, Calif.; University of Oklahoma School of Medicine, Oklahoma City, 1927; member of the American Academy of General Practice; member, and past vice-president and secretary of the staff of the Hawthorne Community Hospital; on the staff of the Centinela Valley Community Hospital in Inglewood; died in Inglewood July 9, aged 56, of arteriosclerotic heart disease.

Robinson, Fred Lawrence ⊕ Dearborn, ity of
Michigan Medical School, Ann Arbor, 19. World
War I; on the staffs of the Mount Carme l in
Detroit and the Oakwood Hospital; died Ju of
coronary disease.

Robinson, Marion Marshall, Richmond, Ky.; University of Louisville School of Medicine, 1914; served a term on the state legislature; on the staff of the Pattie A. Clay Infirmary; died July 1, aged 71, of coronary occlusion.

Rogers, William J., Connerville, Okla. (licensed in Oklahoma under the Act of 1908); died June 24, aged 84.

Ryan, Terence Cullen ⊛ Springfield, Mass.; Harvard Medical School, Boston, 1924; certified by the National Board of Medical Examiners; on the staffs of the Wesson Memorial Hospital and the Mercy Hospital, where he died July 6, aged 58, of coronary sclerosis with occlusion.

Ryan, Thomas Addis, Albany, N. Y.; Albany (N. Y.) Medical College, 1893; an associate member of the American Medical Association; served on the staff of St. Peter's Hospital; died Aug. 1, aged 91, of coronary thrombosis.

Salvatore, Victor L., New York City; Fordham University School of Medicine, New York City, 1916; died July 9, aged 66, of adenocarcinoma of the bladder.

Sanborn, Warren Bigelow, Harmony, R. I.; Atlantic Medical College, Baltimore, 1909; veteran of World War I; served as superintendent of the Augusta (Maine) General Hospital and the State Home and School at Providence; died June 16, aged 78.

Sarnelli, Ciriaco A., New York City; Regia Università di Napoli Facoltà di Medicina e Chirurgia, Italy, 1923; member of the Medical Society of the State of New York; died in the Neurological Institute July 18, aged 58, of bronchogenic carcinoma with metastases to the brain.

Schuldt, Theodore Scott, Pierceton, Ind.; University of Louisville (Ky.) School of Medicine, 1917; member of the Indiana State Medical Association; served as county health officer; veteran of World War I; died in Columbia City July 1, aged 67, of cerebral hemorrhage and arteriosclerotic heart disease.

Seal, Herman ⊕ Captain, U. S. Navy, retired, Encino, Calif.; Tulane University School of Medicine, New Orleans, 1922; retired from the regular Navy January, 1946; member of the American Academy of General Practice; on the staff of the Valley Hospital in Van Nuys; died July 2, aged 56.

Seiler, Elizabeth S., Milwaukee; Ludwig-Maximilians-Universität Medizinische Fakultät, München, Bavaria, Germany, 1921; died July 16, aged 61.

Shearer, Harry Arthur ⊕ Beloit, Wis.; Marquette University School of Medicine, Milwaukee, 1919; member of the American Academy of Ophthalmology and Otolaryngology; specialist certified by the American Board of Otolaryngology; veteran of World War I; served on the staff of the Beloit Municipal Hospital; died in the University Hospital, Madison, July 27, aged 62, of pneumonia and diverticulitis.

Sherk, Joseph Huber ⊕ Midland, Mich.; Detroit College of Medicine, 1907; served as member and president of the school board; for many years on the Midland City Planning Commission; died June 8, aged 73, of coronary occlusion and cerebral thrombosis.

Sibley, Harry Alonzo ⊕ Pontiac, Mich.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1907; past-president of the Oakland County Medical Society; served on the board of education and as school physician; on the staffs of the Pontiac General and St. Joseph Mercy hospitals; died July 10, aged 74, of cerebral hemorrhage.

Simmons, Richard John ⊕ Elizabeth, N. J.; St. Louis University School of Medicine, St. Louis, 1942; veteran of World War II; died in the Veterans Administration Hospital, Albany, N. Y., July 18, aged 42.

Simpson, Charles J., Westminster, Texas; University of Louisville (Ky.) Medical Department, 1892; died in Sherman June 3, aged 86.

Sisson, Mabel Cornelia, Bayside, N. Y.; Boston University School of Medicine, Boston, 1899; died July 26, aged 82, of arteriosclerotic heart disease and cerebral thrombosis.

Si **Donnie,** Dade City, Fla.; Kentucky School of
M ville, Ky., 1898; an associate member of the
An l Association; died June 10, aged 83, of arterio-
scle

Skogen, Thomas T., Dell Rapids, S. D.; Minneapolis College of Physicians and Surgeons, Minneapolis, 1900; served as mayor of Flandreau; died in Duluth, Minn., June 22, aged 91, of carcinoma of the prostate with metastases.

Sloan, Edgar Hamlin, Ben Avon, Pa.; Baltimore Medical College, Baltimore, 1898; veteran of World War I; served as a member and president on the staff of the Suburban General Hospital in Bellevue; last June was given an honorary degree of doctor of laws by Geneva College, Beaver Falls; an associate member of the American Medical Association; died July 16, aged 86, of coronary occlusion.

Smith, Darwin Elbert ⊕ Corbin, Ky.; Medical College of Virginia, Richmond, 1938; member of the American Academy of General Practice; veteran of World War II; on the staff of the Southeastern Kentucky Baptist Hospital, where he died April 29, aged 46, of coronary occlusion.

Smith, Gideon Davis, Kenmore, N. Y.; Niagara University Medical Department, Buffalo, 1896; an associate member of the American Medical Association; on the courtesy staffs of the Millard Fillmore and Kenmore Mercy hospitals in Buffalo; died in Bluff Point July 18, aged 83, of coronary occlusion.

Smith, Greene Hampton, Sr. ⊕ Birmingham, Ala.; University of Tennessee College of Medicine, Memphis, 1916; member of the American Academy of General Practice; veteran of World War I; on the staffs of the Birmingham Baptist Hospital and the Jefferson-Hillman University Hospital, where he died June 6, aged 67, of brain tumor.

Smith, John Edward Vincent, Bayville, N. Y.: New York Homeopathic Medical College and Flower Hospital, New York City, 1934; veteran of World War II; physician for the fire department; on the staff of the Huntington (N. Y.) Hospital; died in the Veterans Administration Hospital, Brooklyn, July 16, aged 47, of Laennec's cirrhosis.

Smith, Paul Elmer ⊕ Bloomington, Ind.; University of Kansas School of Medicine, Kansas City, Kan., 1934; formerly on the staffs of the New Jersey State Hospital in Trenton, and the Richmond (Ind.) State Hospital; died Aug. 26, aged 53, of aortic stenosis.

Smith, Sigmund Ludwig ⊕ New York City; Friedrich-Wilhelms-Universität Medizinische Fakultät, Berlin, Prussia, Germany, 1925; veteran of World War II; retired from the Veterans Administration Feb. 1, 1954; died July 2, aged 53, of myocardial infarction.

Spencer, Harvey ⊕ Ann Arbor, Mich.; Yale University School of Medicine, New Haven, Conn., 1924; certified by the National Board of Medical Examiners; member of the American Psychiatric Association; associate psychiatrist, health service, University of Michigan; formerly staff psychiatrist at the Austen Riggs Center in Stockbridge, Mass., where he was trustee and vice-president of the public library; died in the Massachusetts General Hospital, Boston, July 11, aged 59.

Spurgeon, Leota, Tipton, Ind.; Indiana University School of Medicine, Indianapolis, 1911; died June 27, aged 73, of congestive heart disease and arteriosclerosis.

Stankus, Ignatius John, Philadelphia; Indiana University School of Medicine, Indianapolis, 1910; an associate member of the American Medical Association; died in St. Agnes Hospital July 22, aged 81.

Stansbury, Eugene Milton, Vermillion, S. D.; University of Nebraska College of Medicine, Omaha, 1909; member of the South Dakota State Medical Association and the American Academy of General Practice; professor of obstetrics and gynecology at University of South Dakota School of Medical Sciences; veteran of World War I; died July 18, aged 75, of coronary disease.

Stokey, Fred Eicher, South Hadley, Mass.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, Chicago, 1912; retired medical missionary; veteran of the Spanish-American War; died July 14, aged 76, of acute coronary thrombosis.

Stoll, Harry J., Wooster, Ohio; Rush Medical College, Chicago, 1900; fellow of the American College of Surgeons; on the staff of the Wooster Community Hospial; died July 22, aged 80.

Sullivan, Dennis William ⊕ Lieutenant Colonel, U. S. Army, retired, Santa Monica, Calif.; Ensworth Medical College, St. Joseph, Mo., 1911; veteran of World War I; entered the medical corps of the U. S. Army in 1920; became a lieutenant colonel in 1937; retired April 30, 1942; died in the Veterans Hospital Center in Los Angeles June 2, aged 73, of mediastinitis with empyema due to perforated esophageal peptic ulcer.

Svoboda, Joseph Edward, Cleveland: Ohio State University College of Medicine, Columbus, 1928; veteran of World War II; on the staffs of St. Ann Hospital and St. Alexis Hospital, where he died July 28, aged 58, of carcinoma of the colon.

Sweet, Robert Ballantine, Fullerton, Calif.; Rush Medical College, Chicago, 1902; specialist certified by the American Board of Otolaryngology; fellow of the American College of Surgeons; veteran of World Wars I and II; died in the Veterans Administration Hospital, Long Beach, July 10, aged 79.

Terrill, Elwyn Eugene ⊕ Los Angeles, Calif.; College of Medical Evangelists, Loma Linda and Los Angeles, 1927; member of the American Academy of General Practice; on the staff of the California Hospital; died July 30, aged 55, of cancer of the liver.

Thometz, Alan Frederick ⊕ Glenview, Ill.; Northwestern University School of Medicine, Chicago, 1947; interned at the Cook County Hospital, Chicago; formerly a resident at the Veterans Administration Hospital in Hines; service with the U. S. Public Health Service terminated Nov. 29, 1949; died in the Resurrection Hospital in Chicago Aug. 4, aged 33, or coronary thrombosis.

Thompson, Charles Edward Percy ⊕ Fairhaven, Mass.; Boston University School of Medicine, 1903; formerly on the Fairhaven School Committee, school physician, and on the board of health; a member of the associate staff of St. Luke's Hospital in New Bedford, where he died July 30, aged 76.

Thorn, Druery Rodgers ⊕ Kansas City, Mo.; Jefferson Medical College of Philadelphia, 1921; on the staffs of St. Luke's Hospital and Kansas City General Hospital, where he was at one time medical director; died Aug. 12, aged 63, of coronary occlusion.

Trainor, Joseph Aloysius ⊕ Cambridge, Mass.; College of Physicians and Surgeons, Baltimore, 1904; College of Physicians and Surgeons, Baltimore, 1905; died July 13, aged 80.

Turkel, Ashur Sigmund ⊕ Los Angeles; Stanford University School of Medicine, San Francisco, 1933; died July 14, aged 52, of coronary disease.

Walsh, Edmund A., Springfield, Ill.; College of Physicians and Surgeons of Chicago, 1897; served on the staff of St. John's Hospital, where he died July 21, aged 81 of grade 1-2 epidermoid carcinoma of the tongue.

Warren, Edward Crawford ⊕ Bay City, Mich.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1892; died in Vanderbilt Aug. 6, aged 86, of uremia.

Wiley, Harold Williams ⊕ Lansing, Mich.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1912; past-president of the Ingham County Medical Society; veteran of World War I; director of procurement and distribution of blood for the state health department laboratories; for many years on the staffs of the Edward W. Sparrow and St. Lawrence hospitals; died July 15, aged 67, of coronary occlusion.

Williams, Donald Lee ⊕ Garden City, Kan.; University of Kansas School of Medicine, Kansas City, 1953; interned at the University of Kansas Medical Center in Kansas City, Kan.; died in Greensburg July 25, aged 31, of injuries received in an automobile accident.

Williams, Pierce Lee ⊕ Cordele, Ga.; Atlanta College of Physicians and Surgeons, Atlanta, 1913; member of the American Academy of General Practice; past-president of the Crisp County Medical Society; on the staff of the Crisp County Hospital, where he died July 9, aged 68, of acute coronary insufficiency.

Zimmerman, Mason Woodward, Rydal, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1888; on the staffs of the Wills Eye Hospital and Germantown Dispensary and Hospital in Philadelphia; died Aug. 11, aged 96.

FOREIGN LETTERS

COLOMBIA

Medical Bibliography.—The Bogota medical group, Unidia (Unidad para Diagnostico y Tratameinto), has published a quarterly journal, *Unidia*, for the last four years. In the July, 1956, issue the Unidia librarian has indexed all the Colombian medical literature published during the first semester of 1956 in the 17 Colombian medical journals. The greatest number of articles were on gastrointestinal diseases, medical societies, medical education, gynecology, obstetrics, psychology, and pediatrics.

DENMARK

Activities of Danish Medical Association.—The central committee of the Danish Medical Association has classified its activities as national and international. The first category includes such standard problems as the dealings between hospital medical staffs and police anxious to get information about accident cases admitted to hospital and ethical limits of advertising. On the international level, the committee reports a request from the American Medical Association for advice on how the American tourist who falls ill while traveling in Denmark may secure the best medical care under the best conditions. The Danish Red Cross Society renders assistance in such cases. The British Medical Association requested information about the Association of Junior Physicians, a branch of the Danish Medical Association to which there is, apparently, no counterpart in England. The Norwegian Medical Association desired information about the study of the history of medicine with reference to the organization of a society devoted to this subject in Norway. The Danish Medical Association in turn requested reprints of articles on this subject from this new society in Norway. The Zim Israel Navigation Company, Limited, invited Danish physicians specializing in rheumatism and arthritis to visit the warm springs of Israel. The invitation was forwarded to four physicians. Another invitation came from the 58th German Arztetag in Baden-Baden. The Danish recipient of this invitation found himself the object of the warmest hospitality and profited greatly from the discussions.

BCG Vaccination of Newborn Infants.—Dr. F. Tudvad and coworkers (*Danish Medical Bulletin*, volume 3, July, 1956) reported that in 1950 large-scale BCG vaccination of newborn infants was carried out. All the mothers confined in a municipal maternity hospital were invited to have their babies vaccinated with BCG vaccine unless the babies were ill or premature; 1,330 babies were so vaccinated, and 829 served as controls. The vaccine was given by intracutaneous injection in the deltoid region within a few days of birth. Of the 1,330 babies, 710 were tested for the Moro reaction two months after vaccination; there was a negative reaction in only 5. A follow-up examination of 1,199 vaccinated babies revealed that abscesses had developed in 33 of them (2.75%) within a year of the vaccination. This abscess rate was higher than that for children vaccinated with BCG at a later age. In other respects the outcome of this experiment was favorable to the vaccinated infants in respect of gains of weight. The data collected by the authors of this report failed to give a clear answer to the question of whether the tuberculin positivity conferred by the BCG vaccination of the newborn infant lasts as long as or longer than that conferred by the BCG vaccination of older children.

In *Ugeskrift for læger* for Aug. 9, Dr. E. Groth-Petersen says that, in principle and in order to be consistent, he favors BCG vaccination at birth, but in practice such vaccination presents difficulties of technique and complications are more frequent than with older children. The risk of accidental infection of the newborn infant with virulent tubercle bacilli is comparatively small. Because there is such a risk, however, most Danish phthisiologists prefer to reserve BCG vaccination of the newborn infant for special cases only, but every child who is tuberculin-negative when one year old should have the benefit of this measure. To emphasize the importance of this advice, the author points out that the overwhelming majority of the 350 children found in Denmark to be suffering from tuberculosis in 1954 and 1955 were below school age.

A Lifelong Investigation of Twins.—In the *Danish Medical Bulletin* for August, Harvald and Hauge gave a preliminary report on an investigation of nonselected twins. Of a total of 9,360 pairs of twins born in Denmark in the period 1870 to 1910, 1,900 were thoroughly investigated, a questionnaire being addressed to each twin (or in the case of death to the nearest relative) seeking information about a variety of conditions and the incidence of a long list of diseases. With regard to the 143 cases of tuberculosis (incidence 3.8%), concordance was nearly twice as great for uniovular as for binovular twins. This does not necessarily prove that tuberculosis is a hereditary disease, for the concordance found may simply reflect the fact that uniovular twins have a greater chance to infect each other than binovular twins have. Tuberculosis was the only infectious disease concerning which sufficiently accurate information was obtained on the score of heredity and other problems. The authors hope to treble their present material. When their compilation is completed, they hope to analyze the influence of hereditary factors on the expectation of life. Their preliminary rough estimate suggests that the influence of heredity is minimal compared with environment. They also hope to make an estimate of the influence of heredity on twinning, and on twinning in relation to crime.

Complications of Diabetes Requiring Surgery.—Because of use of insulin and the rise in life expectancy, diabetics now represent 0.5% of the total population of Denmark. On the other hand, the indications for operation have been broadened due to recent advances in medicine. Dr. Knud D. Carlsen in *Ugeskrift for læger* for Aug. 23 states that about half of the diabetics now operated on for their complications have had the disease for more than 15 years. Consequently many of them also suffer from serious deterioration of their cardiovascular systems. At the Aarhus City Hospital, diabetics with complications requiring surgery enjoy the benefits of close cooperation between surgeons, physicians, and anesthetists, whose teamwork is reflected in a falling operative and postoperative mortality. In 1938 and 1939, 49 diabetics in this hospital were treated surgically for complications. In the two-year period ending July 31, 1955, 81 were treated for such complications. In both groups the diabetics represented 0.7% of the hospital's patients. Broadly speaking, the mortality was reduced so effectively that in the second period it was only 33 to 50% of what it had been in the first.

Dumping Syndrome.—Dr. H. K. Lassen (*Ugeskrift for læger*, Aug. 30, 1956) reports a series of 163 patients (147 men and 16 women) who had had a gastrectomy. Follow-up revealed that 86 were well; 61 had only slight discomfort; and 16 (15 men and one woman) had a poor result. Lassen could not explain why some patients in his series suffered from the dumping syndrome (36%) and loss of weight (42%), while others did not. The patients were classified in three groups, according to whether they had done heavy or light work or none at all, but none of these groups was distinguished by any marked difference in the recovery rate. In the same issue an editorial states that in the last 10 or 15 years there has been a growing tendency to favor the operative treatment of gastric and duodenal ulcers because of an operative mortality of less than 1%, the good operative results, and the discovery that the results of medical treatment are worse than anticipated. It is, however, common practice to

---

The items in these letters are contributed by regular correspondents in the various foreign countries.

await the results of two courses of medical treatment before considering operation. Negative radiological findings should be a contraindication to operation, even if symptoms have persisted for years, but, if the distress becomes intolerable, it may be permissible to operate in the face of negative radiological findings, as a low-level duodenal ulcer may have not been visible on the roentgenogram. Gastroenterostomy is less in favor than formerly because the ultimate results have been disappointing. This observation does not apply to patients over 60 years of age.

FRANCE

Epidemic of Typhoid.—At the meeting of the Medical Society of Paris Hospitals on June 22, Ferrabouc and Bernard presented an account of a typhoid epidemic starting on Jan. 15, 1954, in Lyon and involving 158 young soldiers in a garrison of 2,327. One patient died. This was one of the largest epidemics occurring in the army in peacetime. Of the 158 patients, 137 had been vaccinated. The authors suggested that an attempt be made to heighten the immunity of the soldiery by increasing the number of vaccinal injections from three to four. This method was successful in another garrison in controlling an epidemic of salmonellosis due to Salmonella schottmülleri.

Hypophysectomy for Cancer of the Breast.—At the June 29 meeting of the same society, D. Lebeau and co-workers reported on a series of 25 patients who had undergone hypophysectomy for cancer of the breast. They concluded that (1) the operation is contraindicated in patients with hepatic metastases, but it is indicated in those with metastases to the bones or lungs, (2) if each patient's condition is satisfactory before the operation the case fatality rate is small thanks to preoperative and postoperative treatment with cortisone and corticotropin, and (3) in 90% of the patients who have hypophysectomies the pain is immediately relieved. Results observed in patients with cancer of the prostate, testis, or uterus were not as good.

Hepatic Siderosis.—At the same meeting J. Lereboullet and co-workers reported the frequency of hepatic siderosis in alcoholics based on the findings of 270 autopsies and 80 specimens from needle biopsy. They observed a deposit of iron in the livers of 66% of the patients with cirrhosis, 58% of the patients with precirrhotic conditions, and 59% of the alcoholics. In all patients with hepatic siderosis the authors found an excess of iron pigment in such organs as the spleen, pancreas, myocardium, kidney, and testis. They found that the proportion of patients with nervous manifestations who had siderosis was greater than that of those without nervous manifestations. Of 20 patients with delirium tremens they found iron in 80%; of 10 patients with alcoholic encephalopathies they found iron in 80%; and of 14 patients with polyneuritis they found iron in 75%.

Treatment of Trichomoniasis.—At the meeting of the French Society of Gynecology, Carcia reported that a series of 80 patients whose vaginal discharge contained Trichomonas vaginalis was treated with two to eight insufflations of ozone into the cervical canal and the vagina. In all patients the leukorrhea, vaginitis, and trichomoniasis disappeared. In 55, two or three insufflations were enough. Ozone is harmless to the tissues, acts as a deodorant, and is strongly bactericidal.

Prednisone in Dermatology.—In *La presse médicale* (June 23, 1956) E. Sidi states that prednisone applied locally does not give better results than cortisone. He gave prednisone by mouth to 101 patients suffering from eczema, generalized psoriasis, pemphigus, and erythroderma ichthyosiforme congenitum. The clinical results were good, 80% of the patients showing improvement. The drug is indicated in the treatment of pemphigus, acute lupus erythematosus, and other acute dermatoses. In half of the patients receiving a dose of 20 mg. per day edema appears, the serum potassium level drops, and psychic disturbances are likely to occur. Treatment with this drug should not be suddenly discontinued.

INDIA

Effect of Chlorpromazine in Aminopyrine-Induced Analgesia.—M. L. Gujral and co-workers (*Journal of the Indian Medical Profession*, August, 1956) state that, since chlorpromazine is alleged to enhance the analgesic effects of morphine, meperidine, and aspirin, they have studied its effect on analgesia induced by aminopyrine. Albino rats were divided into four groups of 10 each. Each group was given a dose of a drug, combination of drugs, or placebo and tested for analgesia. The groups were rotated at intervals of one week and at the end of the experiment all the animals had received the same tests. Chlorpromazine was found to enhance the analgesic effect of aminopyrine. There was no change, however, in the time of peak effect and duration of analgesia.

Diagnosis of Leprosy.—Nerurkar and Khamolkar (*Indian Journal of Medical Research*, July, 1956) state that millions of acid-fast bacilli can be easily demonstrated in every microscopic field of a smear prepared from a lepromatous skin. It is, however, difficult to find these organisms in a smear from a patient suffering from the tuberculoid type of leprosy, and still more difficult to demonstrate the organisms in contacts of leprous patients or in smears of patients after treatment with sulfones. Routine skin smears from such patients almost always give negative results. In 1952 a different technique of concentration of leprosy bacilli was made available. The authors used fluorescence microscopy on 20 subjects (18 patients with tuberculoid leprosy and 2 contacts without any clinical signs of this disease). Of the 18 patients, one was treated with diaminodiphenylsulfone for about five years. Acid-fast bacilli were found in all these patients without difficulty. As a control, skin biopsy specimens were obtained from persons who attended the hospital for minor injuries. None of these showed acid-fast bacilli. The advantages of the method are that (1) the pressure mincer, being hand operated, can be used in any part of India even when electricity is not available; (2) crushing of the tissue is thorough and easy; and (3) the fluorescing organisms are more easily seen against a partially dark background than with the Zeihl-Neelsen staining method and there are therefore fewer chances of missing isolated organisms.

World Health Day.—April 7 this year was devoted to educating the public regarding the eradication of insect-borne diseases. Local chapters of the Indian Red Cross enthusiastically supported the public health authorities and the World Health Organization in conducting campaigns throughout the country. They organized public meetings, exhibited health films, and participated in disinfecting wells and other mosquito breeding places. Pamphlets on insect vectors were freely distributed.

Response of Guinea Pigs to Histamine Aerosol.—M. L. Gujral and co-workers (*Journal of Postgraduate Medicine*, July, 1956) reported their observations on the relative potency and duration of action of antihistamines by exposing guinea pigs to histamine aerosol. They found that a previous exposure to histamine aerosol does not significantly influence the response of guinea pigs subjected to a second exposure three hours later. The amount of histamine required to produce bronchoconstriction when histamine was given by aerosol was found to be a very small fraction of the intravenous lethal dose. An occasional animal was found to have a refractory response to histamine aerosol and such animals were dropped from the test groups. Attempts to reproduce narcosis, which has been reported after intracardiac injection of histamine, by intraperitoneal injection ended in failure. Large doses resulted in gastroduodenal ulceration and sometimes perforation.

Response of Endocrine Glands to Irradiation.—T. C. Wasson, in the *Journal of the Indian Medical Association* (Aug. 16, 1956), says that radiotherapy of the endocrine glands is cheap and safe, and elicits a quick response. The technique is simple and requires no hospitalization or after-care. Radiosensitivity differs from gland to gland and in the same gland at different times.

The variation is directly proportional to the functional activity of the cells. The pancreas and adrenals are unsuitable for radiotherapy, as they are surrounded by tissues that are more radiosensitive, and, therefore, their exposure to the action of x-rays cannot be undertaken without damaging the surrounding tissues. The pituitary, thyroid, ovary, breast, and thymus glands can be irradiated without harm. These glands during their periods of normal activity are radioresistant and become radiosensitive only when their functional activity is accelerated. During this stage irradiation will curb their activity and bring it down to normal. Hypofunctioning of a gland is a complicated phenomenon. It is chiefly due to surgical excision, tumor formation, or a cause that reduces the number of secreting cells. It is therefore not possible to make up the deficiency of the quantity of the hormone by stimulation of the remaining cells. On the other hand, if the secreting tissue is not reduced and the deficiency is purely functional, small doses of x-ray do stimulate the glands. In young girls approaching puberty, one small dose given for early, scanty, or painful menstrual periods will produce the desired effect. Hypofunction of the testes is invariably secondary to hyperactivity of the pituitary and thyroid glands, and their irradiation therefore has a favorable influence on the testes.

Peptic Ulcer.—Mukherjee and co-workers (*Journal of the Indian Medical Association*, Aug. 1, 1956) noted an increase in the incidence of peptic ulcer in West Bengal in recent years. Men in the fourth decade of life comprised the largest percentage of the patients, and the role of stress was evident in the pathogenesis of the disease. In the authors' series of 82 patients, all had duodenal ulcer. Some were treated with a new anticholinergic drug, oxyphenonium bromide, and preliminary observations suggest that, without an antacid supplement, the drug, given in doses ranging from 15 to 60 mg. in 24 hours according to severity of symptoms, produces beneficial effects clinically as well as radiologically in three weeks' time. Relatively few side-effects were observed.

NORWAY

Lung Cancer and Smoking.—Two articles in *Tidsskrift for den norske lægeforening* for Aug. 15 approach lung cancer from somewhat different angles. Dr. Roald Opsahl emphasizes the comparative rarity of primary lung cancer in Norway between 1916 and 1935, during which period, of 2,005 cases of cancer verified by postmortem examinations, only 56 were primary cancer of the lung. These were equally divided between the sexes and included only two patients in whom there was a record of heavy smoking. After pointing out that the death rate from lung cancer has tripled in Norway in the last two decades, Opsahl censures the government on the score of its passive attitude toward cigarette smoking, from which it derives a certain revenue. He also deplores the failure of the National Cancer Association to wage a more vigorous campaign against the inhaling of cigarette smoke. The other article, by Dr. Einar Pedersen, draws attention to the fact that Norway and Denmark are at present the only countries in the world in which a scheme has been adopted for the systematic review of death certificates in order to examine the diagnoses of lung cancer. Thus, in 1953 there were 209 cases originally so diagnosed in Norway, but, on review, 24 of these diagnoses had to be altered. The author further states that in 1930 only 0.9% of all the deaths from cancer in Norway were due to cancer of the respiratory tract, whereas the corresponding figure for 1952 was 3.6%. Up to 1954, the rise seems to have been limited almost exclusively to the urban male population, and for this group the rise has been and still is great. There is also a tendency for the peaks of the age curves for successive years to shift toward older age groups.

The Dangers of Prolonged Pregnancy.—In August the Northern Association for Obstetrics and Gynecology met in Oslo. The first subject dealt with was prolonged pregnancy, the sinister significance of which has been preached for many years by Dr. K. Skajaa, who is in charge of the Oslo Municipal Maternity Hospital. The present-day teaching that the infant mortality rate at birth rises from 1% when pregnancy has lasted the normal 280 days to 4% when it has lasted 294 days or more is a tribute to Skajaa's pioneer work in this field. A study (*Acta obstetricia et gynecologia scandinavica*, volume 35, part 2, 1956) by Dr. Arne Strand states that in the period 1918 to 1929 no special consideration was given to prolonged pregnancy. This period was compared with that between 1947 and 1955 when special attention was paid to this problem. A series of 10,151 deliveries was studied. In the first period 3,288 patients and in the second 2,092 were primiparas. The outcome of a confinement was influenced by the age of the mothers, whether they were primiparas or multiparas, the duration of the pregnancy, the weight of the infants at birth, and other factors. Primiparas 35 years of age or older showed a greater tendency to prolonged pregnancy than those who were younger. The rates for antenatal, intranatal, and postnatal infant mortality rose with the duration of pregnancy after it had lasted 280 days, and this was particularly the case with primiparas. Strand concludes that the induction of labor at term, after critical evaluation of each case, appeared to have reduced the perinatal death rate, that complications are not more serious after induced than after spontaneous labor, and that the speedy induction of labor is the best treatment after the indications for it have been determined.

PORTUGAL

Sickling of Erythrocytes.—Leite and Ré (*Arch. Inst. Pasteur Algérie* 33:344, 1955) studied the sickling of erythrocytes in the Portuguese African province of Guinea. This province has many tribes, including Melano-Africans and Ethiopians. These tribes do not mix, and, going from the coast to the interior, one finds a stratification in the distribution of tribes, resulting from the successive original invasions. The authors investigated the percentage of sickle cells in blood samples from random groups in each native tribe. About 6,000 blood specimens were examined. The highest values (17 to 23%) were found in the last invaders of Guinea (Mandinga and Fula tribes) and the lowest (1.7 to 8.3%) in the aboriginal populations. The authors believe that a high percentage of sickle cells is not a common characteristic of all African Negro populations, as others have stated, but a peculiarity of the later invaders of the African continent, who probably came through Ethiopia. An important confirmation of this view was found in another investigation by these authors. They investigated in the interior of Angola a tribe of Bochiman, surely the oldest invaders of the African continent, who are still free from hybridization, and, among 249 natives, they did not find a single case of sickling.

Yellow Fever.—Cambournac and co-workers (*An. Inst. med. trop.* 12:101, 1955) collected blood in 61 zones of Angola, mostly from 1,549 children under 15 years of age, and performed the neutralization test for yellow fever virus in mice. Only 38 specimens were positive. The authors believe that the positive results obtained in the north inland and coastal regions of Angola are probably due to the presence of the yellow fever virus there but that the scarcity of positive results found on the southern frontier might have been due to vaccination of the natives. In the north the many rivers, bordered by dense forests; the long rainy season (six to eight months); and the great number of monkeys make eradication of the virus difficult.

SWITZERLAND

Prednisone in Treatment of Malignant Lymphomas.—At the Medical Clinic of the University of Geneva, Dr. Dubois-Ferrère and co-workers have treated adults with acute leukemia with large doses (1 to 2 gm. daily) of cortisone. This treatment was continued for 8 to 21 days. More recently they have used prednisone in daily doses of 1 gm. and have observed a rapid and sometimes amazing regression of adenopathies and of parenchymatous and pleural effusions, sometimes amounting to complete disappearance of all roentgenologic signs. Although recurrence can be expected, the relief while it lasts is most gratifying.

Poliomyelitic Antibodies.—R. Martin-Du-Pan and co-workers have studied the poliomyelitic antibodies in 163 normal persons of all ages living in Geneva and coastal communities, particularly in families of pediatricians. The authors do not believe that the presence of antibodies in the serum means total immunity. They observed that the percentage of patients showing antibodies in their serum increases steadily beginning with those 6 months old. They further concluded that immunity of the population of Geneva is about the same as that of Switzerland as a whole. The children of pediatricians and physicians working in virus laboratories showed no greater antibody titer to poliomyelitic antigens than did other children living under similar conditions. This may be explained by the fact that physicians and other persons who have greater than average contact with poliomyelitis virus take precautionary measures to avoid infection.

UNITED KINGDOM

Pertussis Vaccine.—A further report on the results of vaccination of children against pertussis was made by a group of workers appointed by the Whooping Cough Immunization Committee of the Medical Research Council (*Brit. M. J.* 2:454, 1956). Two series of field trials were made in which 28,799 children were followed up for an average of two years after inoculation with pertussis vaccine. Severe local or general reactions were not encountered, and there was insufficient evidence to show that pertussis vaccine precipitated convulsions or initiated serious cerebral damage. In three cases of poliomyelitis occurring within 28 days after injection of the vaccine, paralysis was confined to the limb injected. Two types of vaccine were used, one from 24-hour or 48-hour cultures of a single strain on Bordet-Gengou medium containing horse blood, the other from culture in liquid medium. Formalin was used as a bactericide and phenol or thimerosal as a preservative. This vaccine gave poor protection. Another vaccine was made from a mixture of four, six, or seven freshly isolated strains that had been subcultured on very few occasions before being freeze-dried. Three types of vaccine were made with Bordet-Gengou medium containing sheep's blood, human blood, and a liquid medium respectively. All were killed and preserved with thimerosal. Field studies showed that three of five batches of this second vaccine were as effective as a reference vaccine made with American strains and supplied by the Michigan Department of Health and that the vaccine prepared by the State of New York Department of Health from the same American strains as the reference vaccine, but grown in a liquid medium, was as effective in a preliminary trial as the reference vaccine. While the clinical trials were in progress, laboratory tests were made to determine the ability of the vaccines to protect mice against intracerebral pertussis infection. There was a correlation between protection in children against pertussis and the three following laboratory tests: protection of mice against intracerebral infection with Hemophilus pertussis, production of a specific agglutinin in mice, and production of a specific agglutinin in children. It does not necessarily follow that the laboratory tests measure directly the factor or factors responsible for the production of immunity in children. Agglutinin production in children has been accepted by some workers as evidence of protective potency, and the tests reported by the committee support this conclusion. As it would hardly be practical to test each batch on children, the mouse intracerebral test is considered to be the most satisfactory one. A British standard pertussis vaccine has been established in terms of which other vaccines may be assayed. It is freeze-dried in a 6% dextran solution. The committee considers that, before a pertussis vaccine is issued, it should be submitted to the mouse intracerebral protection test to ensure adequate potency.

Carbutamide and Diabetes.—Carbutamide is used orally for the treatment of diabetes (*British Medical Journal*, Aug. 25, 1956). Trials were organized in six centers in England and Scotland on a total of 193 inpatients and outpatients. The results confirm the German observation that the type of patient that responds best to this drug is the middle-aged or obese diabetic who has never been ketotic and who needs less than 30 units of insulin daily. In general, grossly obese diabetics were not included in the trial. All groups carrying out these investigations concluded that, in the right type of diabetic, carbutamide, in doses of 1 to 4 gm. daily, reduces the blood sugar level to within normal limits for most of the day. It does not affect glucose tolerance or have any influence on the postprandial rise in the blood sugar level, and, contrary to the view expressed in Germany, treatment must be continuous and not intermittent. The drug is without effect on diabetic ketosis or in patients who rapidly develop ketosis or even have acetonuria. The fasting blood sugar level appears to be an important factor in assessing the effect of the drug. If this is more than about 275 mg. per 100 ml. after insulin administration has been stopped, the drug is not likely to be of value in producing a normoglycemia. The reports emphasize the danger of withdrawing insulin in apparently suitable persons with stable diabetes not apparently liable to ketosis. Several such patients developed severe diabetic ketosis within a few days when given carbutamide. This shows that, if a diabetic receiving insulin is transferred to treatment with the new drug, he must be seen daily or hospitalized after the insulin administration is stopped.

Diabetics in whom carbutamide failed had higher insulin requirements than those who responded. If insulin is essential for treatment, then any attempt to replace it by carbutamide will result in a serious relapse. Response nearly always occurred in patients whose diabetes commenced after the age of 40 years. Studies of arteriovenous blood sugar differences and of the changes in serum inorganic phosphorus level provided no evidence that the new drug increased the effectiveness of the peripheral action of insulin. Carbutamide is ineffective in patients suffering from sepsis. Diet remains the mainstay of treatment for the middle-aged diabetic, and carbutamide is only indicated in a comparatively small group. Although it may control the blood sugar level, the British clinicians are concerned about the development of retinitis and nephropathy. Will the drug control these? A most disturbing feature of the reports is the high incidence of side-effects. The incidence of sulfonamide rash was 9%; persistent neutropenia occurred in a number of patients; and hypothyroidism, drug fever, and depression of blood platelets with purpura were reported. Carbutamide is, therefore, a dangerous substance, unsuitable for the long-term control of mild diabetes and definitely unsuitable for those diabetics needing insulin. It may even cause fatal granulocytopenia and thrombocytopenia and should be used only under the most careful medical supervision.

Explosions in Operating Rooms.—In 1953, the Ministry of Health appointed a committee to investigate anesthetic explosions. The conclusions of the committee (Report of a Working Party on Anesthetic Explosions, London, Her Majesty's Stationery Office, 1956) are based on 36 such explosions. Most of these could have been avoided if the possibility of explosion had been borne in mind and if every hospital had taken routine precautions. Most explosions are due to static electric discharges. It is difficult to ensure that conditions are such that these discharges cannot occur, but if the necessary precautions are taken the chances of an explosion occurring are rare. Most of the explosions investigated were attributed to the use of nonconducting rubber. The routine use of antistatic rubber would eliminate explosions due to static discharges. As soon as reasonable standards for such rubber can be laid down, the Ministry of Health should equip operating rooms with it without delay. It would be a comparatively small item in the hospital budget. Another source of explosions is the use of nonconducting footwear by operating-room personnel. Overshoes should have antistatic rubber on the under surface. Gowns should be made of antistatic fabric tied loosely to reduce the generation of an electric discharge in the clothes beneath. Woolen blankets should not be brought into the operating room, as they may become readily electrified.

Only 5 to 10% of operating rooms in Great Britain have nonconducting floors (rubber or cork). In operating rooms without such floors the danger of explosion can be decreased by dampening the floor or by putting a damp sheet down if evaporation is rapid. If explosive anesthetics are used routinely, the only safe procedure is to lay a new, nonconductive floor. The use of nonconducting paints for floors is being investigated. The best measure to reduce the danger of static discharge is to maintain a high humidity. Most of the explosions occur in abnormally dry weather. All operating rooms should therefore be equipped with an instrument measuring humidity and with a device for increasing it when necessary. It should be the duty of one of the operating room attendants to warn the anesthetist when humidity drops below 50%. An apparatus that ionizes the air so that charges are quickly dissipated is now available, and the committee would like to see how effective it is as an antistatic device. The physiological effects of breathing ionized air should also be investigated. The only sure method of preventing hospital explosions at present is to eliminate all explosive anesthetic agents. The use of substances rendering explosive gases noninflammable should be investigated. Such a substance is commercially available for making gasoline noninflammable. The use of noninflammable xenon and fluorine-substituted anesthetics, which are noninflammable, should be investigated. The report emphasizes that all persons employed in the operating room should be made explosion-conscious.

Cancer and Leukemia in Children.—Health departments all over Great Britain are engaged in an environmental survey that will eventually cover about 1,500 children who died of leukemia or cancer before the age of 10 between the years 1953 and 1955. A preliminary report was made by Dr. Stewart and her co-workers in the department of social medicine, Oxford. Where possible, radiological data are checked from hospital records and the details are noted of the mother's health before and during the relevant pregnancy and of any irradiation, for either diagnostic or therapeutic purposes, that she may have received during pregnancy. A note is also made of any case of malignant disease in the family, any degree of consanguinity between parents and grandparents, and certain features of the child's diet and home environment. Similar data have been collected from control children of the same age and sex living in the same district. One reason for attempting this nationwide survey was the possibility that the peak of leukemia mortality in early life might be explained by the action of weak irradiation initiating malignant changes in a fetus or a very young child. From the figures collected so far it appears that the number of mothers of leukemic children who had a radiological examination of their abdomen during the relevant pregnancy was twice that of the mothers of the control children. This was also true for the mothers of children dying from malignant disease. It has also been established that the dose of irradiation received by the fetal gonads frequently exceeded 2.5 r. The present investigation suggests that, besides causing genetic damage, diagnostic radiology during pregnancy may occasionally cause leukemia or cancer of the unborn child.

A New Syndrome.—Baron and co-workers (*Lancet* 2:421, 1956) have described a new syndrome, characterized by a rough, reddened skin on exposure to light similar to that seen in pellagra, a severe but reversible cerebellar ataxia, renal aminoaciduria, a constant large urinary excretion of indole-3-acetic acid, and an increased quantity of protoporphyrin in the feces. This new disease affected four of eight children of a first-cousin marriage. It was thought that the condition might be a disorder of tryptophan metabolism, whereby a metabolic block exists somewhere along the pathway from tryptophan to nicotinic acid. Another possibility is that the syndrome might be caused by a conditioned nicotinic acid deficiency due to the diversions of tryptophan from its normal metabolic pathways into the pathways of indican and indolacetic acid formation. All the patients were children. In this disease there may be a variation with age and stress in the requirement for endogenous nicotinic acid, which would explain the clinical deterioration with growth and infectious disease and the possible later improvement in adult life. The renal aminoaciduria was attributed to the poisoning of the kidney tubules by an abnormal indole metabolite. It could also be explained by a primary disorder of amino acid transport processes leading to an abnormal intestinal flora that distorts the normal sequence of nicotinic acid metabolism.

Changing Dietary Pattern.—The latest report on food consumption in Great Britain, issued by the Ministries of Agriculture, Fisheries, and Food (Domestic Food Consumption and Expenditure—1954: Fifth Annual Report of the National Food Committee, London, Her Majesty's Stationery Office, 1956) shows that the pattern of the national diet is changing. The year 1954 was a year of transition from a controlled to a free economy. Before then, meat, fats, and cheese were still rationed and subsidized by the government, but by July, 1954, all direct controls had ended and the only remaining subsidized foods were bread, milk, and welfare foods (dried milk, cod liver oil, and orange juice). By 1954, expenditure on food by the population rose more than food prices and a larger share of the national income was being spent on food. As a percentage of total expenditure on consumers' goods and services, expenditure on food rose steadily from 29.8% in 1938 to 32.1% in 1954, and the daily caloric consumption increased from 3,000 to 3,130. Because this is caloric consumption "as bought" and not "as consumed," allowance must be made for wastage in preparation and cooking. Consumption has risen in all the main food groups except cereals, potatoes, and other vegetables. For meat it rose 12%, for fat and oils 7%, and for sugar and syrup 8%. The decline in cereal consumption has been continuous and is associated with a rising standard of living. Milk consumption has also increased, but that of fish has decreased. The weekly per capita consumption of milk, both fresh and processed, is 5.1 pt. The percentage of calories derived from animal sources has risen steadily to 54 and that of fat to 36.5. In those households with a yearly income of more than $2,500, 40% of the calories of the diet come from fat, 48% from carbohydrate, and 12% from protein.

Certain foods show a class gradient. Thus the consumption of protein, fat, iron, vitamin A, riboflavin, and ascorbic acid is directly proportional to the income of the family, but, except for iron in the low income groups, the intake of the other nutrients is above the recommended allowances of the British Medical Association's committee on nutrition. The diet of the family with a large number of children contains more bread, potatoes, and milk, about the same amount of sugar, but less meat, cheese, fish, fruit, and green vegetables than the diet of the average childless couple. Although the difference between the nutritional standards of households with and without children has widened, it is due not to deterioration of the diet of the large family but to the improvement of that of the small family. The greatest dependence on carbohydrates as a source of energy was found in households with four or more children or with children and adolescents. In families of three children protein consumption is 92% of that recommended by the British Medical Association nutrition committee; in families with four or more children it is 87%. These figures would be higher if a lower extraction rate were used by the millers in the preparation of white flour.

Hunters' Birthplace.—A committee representing the University of Glasgow, the Royal Faculty of Physicians and Surgeons, Glasgow, and the East Kilbride Development Corporation has been organized to raised a fund for the renovation and preservation of the birthplace of William and John Hunter at Long Calderwood in Scotland. A sum of $56,000 is required to restore the fabric of the house and provide an endowment fund for future maintenance; $8,500 has already been raised in Scotland. The committee plans to organize a board of trustees to maintain the house as a memorial, a museum, a place of pilgrimage, and, if sufficient money is forthcoming, a research center. An appeal is being made to all members of the medical profession "to save this national historic monument as a fitting memorial to the two brothers whose names will ever be gratefully remembered for their unique achievements in the advancement of medical knowledge."

High-Energy Radiation Unit.—A new high-energy radiation treatment unit has been opened at Cookridge Hospital, Leeds, and is being developed as a regional radiotherapy center. Funds for this have been provided by the Rockefeller Foundation, the British Empire Cancer Campaign, and the Leeds Regional Hospital Board. The new unit is the first of its kind in the country, as it will combine radiotherapy and radiation research. It shares with the British Empire Cancer Campaign the largest therapeutic source of radioactive cobalt in the country. The unit has been planned to provide new techniques for the treatment of cancer and for research on the physical, chemical, and therapeutic action of high-energy radiation. Physicists, chemists, and radiotherapists will work in collaboration under one roof. The source of high-energy radiation will emit radiation equivalent to a machine working at about 3 million volts.

CANCER AS A CAUSE OF DEATH AMONG PATIENTS WITH OTHER CHRONIC DISEASES

To the Editor:—Doshay (*J. A. M. A.* 156:680-684 [Oct. 16] 1954) has suggested that patients with paralysis agitans are less likely than others to contract cancer. He states: "For reasons as yet unclear, cancer is phenomenally rare in paralysis agitans, despite the fact that the patients are in the age group 45 to 75, when the expectancy of cancer in the general population is high. Only one proved instance of cancer has developed among the several thousand cases I have followed during the past 20 years, and this patient had a rectal cancer, without operation or metastases, for 5 years, until she died during a vascular episode."

The patient material from the Ullevål Hospital (Oslo City Hospitals) has been used in an attempt to study this point quantitatively. All patients discharged alive during the years 1917-1950 with a diagnosis of paralysis agitans or Parkinsonism, a total of 154, were registered. One record could not be located. The records for the other patients were studied, and each record was placed in one of the following four groups: (1) typical paralysis agitans without known etiology, 90 records; (2) postencephalitic Parkinsonism, 16; (3) doubtful paralysis agitans, 40; and (4) probably not paralysis agitans or postencephalitic Parkinsonism, 7. The seven cases in group 4 were omitted from further study. The remaining 146 patients were followed either until death or until July 1, 1955. One hundred eleven patients had died during the observation period, 31 were still alive at the end of the period, and 4 patients could not be traced. The total number of observation years in the material was 763.5. The expected number of deaths from cancer during these years was calculated in the following manner: Males and females were treated separately. The observation years were distributed in 10-year age groups and 5-year calendar year groups and multiplied by the corresponding official cancer death rates in Norway. These calculations gave a total of 3.6 expected cancer deaths in the material. Determination of actual deaths certified as due to cancer was obtained by studying the death certificates of the 111 patients who had died. In three cases the certificate could not be found. A total of seven deaths had been certified as due to cancer. Further information collected for these deaths revealed that the diagnosis had been confirmed by autopsy in two cases. In three other cases the diagnosis was built on reasonably conclusive examinations prior to death. In the remaining two cases the diagnosis was questionable. These results—7 actual deaths versus 3.6 expected—do not lend support to the hypothesis that patients with paralysis agitans are in any way protected from contracting cancer. It may be mentioned that, among the patients with typical paralysis agitans (group 1 above), there were 6 deaths due to cancer against an expected number of 2.0.

It might be said against the method here employed that persons with chronic diseases possibly stay more completely under medical control than the average population, so that cancer will be more frequently diagnosed. Although this probably will not be of any great importance, we thought it might be of interest to compare the actual and the expected number of deaths in patients with other chronic diseases. To do this, we have used the materials from follow-up studies in two groups of patients, one with bronchial asthma and the other with myocardial infarction. More detailed descriptions of these studies have been given elsewhere (Westlund and Hougen: *J. Chron. Dis.* 3:34-45 [Jan.] 1956. Life Insurance Companies Institute for Medical Statistics at the Oslo City Hospitals: Myocardial Infarction: An Epidemic and Prognostic Study of Patients from Five Departments of Internal Medicine in Oslo 1935-1949, *Acta med.. scandinav.*, supp. 315, 1956). The expected number of deaths from cancer has been calculated in the same way as for the group with paralysis agitans. The table gives the results in a condensed form. For comparison, data for the patients with paralysis agitans have also been included. It will be seen from the table that actual cancer deaths in the myocardial infarction group were slightly fewer than expected. On the whole, however, the discrepancies between actual and expected deaths in the table are small. A more detailed account of the study, mimeographed in Norwegian, is available on request.

*Deaths from Cancer, Actual Number and Expected, in Follow-Up Studies for Three Groups of Patients**

					No. of Deaths After Discharge			
					Actual			
		No. of Patients						
Disease	Calendar Yr. of Discharge	Discharged	Not Traced	No. of Observation Yr.	All Deaths	Unknown Cause of Death	Deaths from Cancer	Expected Deaths from Cancer†
Paralysis agitans and Parkinsonism	1917-1950	146	4	763.5	111	3	7	3.6
Bronchial asthma	1917-1936	345	18	5,242.5	183	10	13	11.9
Myocardial infarction	1935-1949	929	0	4,255.5	621	10	17	23.3

* The cause of death is taken from the death certificates.

† Expected number of deaths from cancer is calculated on the basis of the Norwegian cancer mortality rates with regard to age and calendar year distribution.

PSYCHOANALYSIS

To the Editor:—There are some exceptions to be taken to the claims of Freudian psychoanalysis set forth with such conviction in the guest editorial of the July 21 issue of The Journal, page 1160. In reading it one could be led to think that there had not been found anything like vital flaws in its doctrine and that the doctrine had not become much of a controversial issue in psychiatry in general. One need but observe what criticism the doctrine received directly and by implication in some of the papers read at the annual meeting of the American Psychiatric Association this year to become aware of the continuously smouldering conflict that the doctrine's influence in the psychiatric field has provoked and to see that the issue presented is not one to be resolved just by more and more experience and research, but by philosophically reconsidering the principles that are implicated. Some of the papers received rather widespread publicity and served, no doubt, to help keep alive in the popular mind its scepticism about a psychiatry whose doctrinal disunity seems to be so anomalous as it faces the ever-growing incidence of mental disorder in the community. The animus with which this disunity was expressed at that meeting has lead the president of the association to publish in its journal a plea for the adoption of a more tolerant spirit in the treatment of the issue.

The editorial asks for conclusive recognition of psychoanalysis as a scientific discipline. It notes the credit due to Freud for his "discovery of unconscious mental processes." While this unconscious area of the psyche may be seen as part of the evolutional background of man's subjective life, investigation of which therefore involves us at once with the kind of problems that the genetic modality of vital phenomena presents, the editorial seems to overlook its opportunity to claim that Freud had achieved a correct formulation of the genetic process. The key idea of the Freudian doctrine is the genetic idea, and the validity of its claim to being scientific must depend upon the nature of the idea it has adopted.

Freud astutely recognized that the nuclear aspect of so-called functional psychopathology is genetic in its character. He also saw that perhaps the greatest possibility of understanding the basic relationship between organic and psychic phenomena would be seen to exist in a view of the genetic factors that are common to both classes of phenomena. Here he was in agreement with the teachings of Dr. Karl G. Carus who, in Germany in 1831, was expounding the psychic unconscious and the genetic method of understanding it. In principle Freud was also in accord with the theory of degeneration that, in the latter part of the 19th century, was seen by psychiatrists to explain much pathology. But if Freud has achieved a correct formulation of the genetic process in the psychic field, his fame should pervade every sphere of biology, since the process must be identical in nature with that occurring in organic form. Up to now the ontogenetic process has been recognized as the primary and central problem of that science. The application of the Freudian formula to the organic domain should be the test of its validity. The disciple Ferenczi essayed to do some of this with his "bioanalysis." This was consistent, as Freud's formula is mechanistic, paradoxically. It conceives the genetic process as reversible, in spite of the biological impossibilities that this implies. It confuses decomposition with degeneration and involution. Thus the crucial Freudian idea of regression (and restitution) is supported, and it is adhered to although no material tissue changes are found in a patient to correspond to such a process. But the concept of such play of a genetic process, as a principle of pathology, is not used in somatic medicine, and its continued employment in psychiatry must tend to estrange this specialty from the general medical field until the differences are resolved.

No specialty in medicine as much as psychiatry seems to call for an acquaintance with general philosophical principles as basic preparation for research, teaching, and practice. This fact naturally would be recognized distinctly by any doctrine that claims to give anything like a systematic interpretation of psychopathology. But the philosophical position as well as the scientific status of psychoanalysis is ambiguous. It fails to perceive differences in modalities, as when it assumes that the genetic and the mechanistic are interchangeable. It professes to be, in its nature, a science of individuality, since psychiatry perhaps more than any other medical discipline must treat its patient as an individual rather than as a type. But, strictly speaking, science does not know individuals, and this is as true now as when Aristotle said: *"Scientia est de universalibus."* Furthermore, psychoanalysis claims to be scientific in a field where the strictly scientific method again does not apply exhaustively, when it asserts that it has its foundation in biological processes that, in fact, are not understood by biologists or that show no changes of a character that correlate with Freudian mechanisms.

It is necessary to conclude, therefore, that, far from being a basic science, psychoanalysis is itself much in need of whatever reformulation it can undergo that may give it an authentic biological basis. The urgent need of a comprehensive working theory of psychopathology to use in managing the current burden of mental disorder in modern life should not seem to be justification for disregarding this conclusion.

EDUCATION AND NEUROLOGY

To the Editor:—I have just read Dr. Benjamin Boshes interesting article, "The Responsibility of the Graduate Educator in Neurology and Psychiatry" (*J. A. M. A.* 161:1213 [July 28] 1956), and I anticipate that this will not be the only comment on that somewhat hypercritical paper. Dr. Boshes is an experienced neurologist, but I am certain that his experiences with neurological surgeons cannot have all been as bad as his comments would indicate. While I would not deny that in some of the cases he mentioned there was apparently insufficient justification for heroic diagnostic procedures, I should like to assure him that most neurosurgeons have heard of multiple sclerosis and tension headaches. Indeed we spend much of our time discouraging further neurological examinations for the latter, but in some atypical cases we feel that spinal air studies are the more conservative approach. Most of us can readily recall patients who were given "functional" or "degenerative" diagnoses elsewhere only to have such things as platybasia, intramedullary cervical cord tumor, central cervical disks without plain x-ray changes, or midline cerebellar tumors show up on more thorough study. These are not figments of my imagination but actual examples of cases that had been missed by neurologists, some at famous clinics, who had placed too much reliance on the clinical neurological examination. After all, the most important use of air studies and myelography, etc., is to elucidate surgical lesions where the clinical examination will only allow us to be suspicious of such. Who has not seen a chronic subdural hematoma masquerade as a cerebral thrombosis? Dr. Boshes criticizes an unnamed neurosurgeon for an extremely brief hospital record of his history and physical examination, consisting of the following statements: "Intractable headache, no neurological findings. Impression: Intracranial pathology, tumor? Ventriculography." Dr. Boshes states about the neurosurgeon: "he is mechanically oriented, not broadly grounded neurologically." He makes these assertions in such a way as to give the impression of describing a typical neurological surgeon. I wonder what Dr. Boshes thinks we study during our five plus years of specialty training? Oh, yes, where does one find a hospital these days that permits those brief histories and physicals?

ROTATING INTERNSHIPS

To the Editor:—In the Aug. 25, 1956, issue of The Journal, page 1664, I have read with concern the resolution passed by the House of Delegates of the American Medical Association to the effect that the Council on Medical Education and Hospitals be requested to increase its efforts to encourage rotating internships rather than straight internships in all hospitals approved for the latter. If this resolution is followed to its logical conclusion, as a condition for approval straight internships will eventually be abolished in favor of rotating internships. Irrespective of the virtues or faults of either type of internship, there appear to me to be three strong objections to such action. 1. The effort to establish rotating internships universally, presumably of two years' duration, would suggest concern not with the improvement of the quality of internship training but rather with the quantity of interns available for hospital appointments. Such a motivation cannot help but result in a deterioration in the quality of internship training. 2. The A. M. A., in its laudable campaign against compulsory health insurance, has repeatedly emphasized the need for preserving our American free enterprise system. Time and again it has demonstrated the dangers to individual liberty that lie ahead if we permit our free institutions to lose even a fraction of the autonomy that has made it possible for them to achieve greatness. The eventual establishment of a uniform rotating internship would restrict the freedom of action of our free and independent hospitals. 3. An institution, one of whose primary functions and objectives is medical education, cannot help but deeply resent the possible imposition of restrictions in the field of medical education. Certainly our large teaching centers have a responsibility to experiment in educational techniques. I believe that most of us in the field of providing hospital and medical care recognize the fine job the Council on Medical Education and Hospitals is doing in its efforts to improve the quality of training available to recent medical school graduates. I hope that it will continue to use its influence for the academic freedom of those individuals in large teaching hospitals who are dedicated to the provision of optimal training for young doctors.

MISCELLANY

NATIONAL DISEASE AND THERAPEUTIC INDEX

The National Disease and Therapeutic Index, a medical statistical research program, has completed its first few months of operation with the promise of interesting and useful results. Designed to provide information on the nature, scope, and frequency of occurrence of nonfatal disease, injury, and other conditions as seen by the doctor in private practice in the United States, the program involves the compilation of statistical data showing why patients see doctors and what types of treatment they receive. Nearly 800 doctors, located in 27 statistically selected, representative areas in 21 states and the District of Columbia, already are participating in this important project, which has aroused the professional interest of medical men and particularly of medical educators and those involved in both basic and applied research. A recent analysis of the nearly completed national panel showed the following representation by types of practice: 346 general practitioners; 50 obstetrician-gynecologists; 4 obstetricians; 2 gynecologists; 86 surgeons; 110 internists; 50 pediatricians; 17 eye, ear, nose, and throat specialists; 14 urologists; 15 dermatologists; 3 allergists; 21 otolaryngologists; 2 neurosurgeons; and 4 proctologists.

Established to meet the long-recognized need for statistics on morbidity as contrasted with those on mortality, the program was explored thoroughly by members of the American Medical Association staff; representatives of many state, county, and local medical societies; a number of medical educators; and others in the medical profession and allied fields before being put into operation. The nonexistence of reliable data in this area of research and the potential value of such data in both general and specialized medical practice, in research, and in education has been recognized consistently by those consulted.

To accomplish the objectives of the program, a panel of some 864 randomly selected doctors is being established, consisting of approximately 32 men in each statistically selected sample area. The design of the distribution provides for the inclusion of both urban and rural doctors and proper proportional representation of general practice and the various specialties. Each cooperating doctor will report four times per year, giving the age, sex, diagnosis or diagnoses, and treatment used for each patient seen during the course of a 48-hour period once each quarter. In a pilot study conducted with 50 doctors in the Philadelphia area in September, 1955, it was determined that the program was completely feasible and that the required case record for each patient could be completed in less than one minute. Of particular importance to the members of the medical profession and the public is the fact that the names of patients are not involved and the names of reporting doctors are never identified with case records.

To serve as liaison with the reporting doctors and to supervise the operation of the program in each area, 27 coordinators have been appointed. Their function is to assist in enlistment work and scheduling of reporting dates and to do preliminary coding of diagnoses according to the Manual of International Statistical Classification of Diseases, Injuries, and Causes of Death.[1] The reporting doctors are encouraged to use the terminology of the Standard Nomenclature of Diseases and Operations in recording their diagnoses. The coordinators are drawn from among trained medical personnel in each sample area.

The full research facilities of Taylor, Harkins and Lea, Inc., Philadelphia, have been utilized in the organization, development, and operation of the National Disease and Therapeutic Index, and the program has the support of leading ethical pharmaceutical houses. Liaison has been established with the Bureau of Economic Research of the American Medical Association to assure that that organization will be prepared to receive and utilize such data as may, after careful analysis and evaluation, be available. Other organized medical groups and the nation's medical schools should eventually benefit from such useful data as may be developed from time to time as a result of the program.

In summary, the data to be gathered by means of the National Disease and Therapeutic Index eventually should aid medical educators in planning new and revising current curriculums; medical investigators in determining the directions to be taken and the goals to be sought in research; practicing doctors, particularly in their efforts directed toward preventive medicine; health organizations in planning establishment and development of future programs and revision or possible abandonment of current ones; and pharmaceutical manufacturers in research and product development designed to meet current and future needs. Because of the vast scope of the program, it will be some time in the latter part of 1957 before data can be processed and evaluated to determine what may be of benefit to various segments of the profession.

MEDICAL FILM REVIEWS

Coronary Artery Disease: 16 mm., color, sound, showing time 30 minutes. Prepared in 1956 by and procurable on loan from Claude S. Beck, M.D., 2065 Adelbert Rd., Cleveland 6.

This film begins with a discussion of the cause of death in cardiac ischemia and a method of prevention of death that is effective in 90% of these patients. The film also includes a presentation of animal experimentation work; an autopsy specimen demonstration; a description of the operative procedure used on patients, with a discussion of the reasons for the successful results obtained; and a presentation of 10 patients at various periods from one month to three years after operation. The animal experiments presented include the production of anoxia throughout the entire heart as contrasted with that produced in a localized area through ligation of a primary coronary vessel. The latter condition sets up a trigger-like mechanism that may produce cardiac fibrillation and death. The Beck operation, which results in the prevention of death in 90% of patients with cardiac ischemia, is described as follows: (1) mobilization of and placing a ligature around the coronary sinus; (2) abrasion of the pericardium and epicardium; (3) ligation of the coronary sinus on a 3-mm. probe, to maintain that amount of lumen for return flow of venous blood to the right side of the heart; (4) the placing of 0.2 gm. of ground asbestos on the epicardium to stimulate the production of vascular adhesions; and (5) the suturing of both pericardium and pericardial fat to the heart. In dogs in which this procedure is done the heart is protected to the extent that the mortality rate is only 26% after the ligation of the descending ramus of the coronary artery, as compared to a mortality rate of 70% when this procedure is not carried out. The back-flow test of coronary circulation is increased more than 5% after the operation is performed, giving rise to as much as 282 cc. of blood flow per hour in these experiments. Through improvement of communications between coronary arteries, the myocardium is preserved in a better condition. Just prior to the time this film was made, the mortality rate in 100 human beings on whom this type of operation had been performed was 6%. Of the 10 patients presented in this film, 9 are working, and all are either completely relieved or markedly improved since operation. Some mention should be made, in the film, regarding the selection of patients and the indications for and contraindications to the operation.

Dr. Beck introduces the film in person and narrates it well. Color is excellent, and the exposure is adequate at all times. Since this film includes much scientific data as well as operative technique, it would be useful in teaching, especially at the graduate level. It would be of special value for graduate teaching in cardiac surgery.

MEDICAL LITERATURE ABSTRACTS

INTERNAL MEDICINE

Treatment of Carbon Monoxide Intoxication by Cytochrome. J. F. Gros and P. Leandri. Presse méd. 64:1356-1357 (July 28) 1956 (In French) [Paris, France].

Carbon monoxide injures the cytochrome system. Cytochrome treatment in carbon monoxide intoxication is therefore of great importance. Its therapeutic effects vary according to the previous condition of the victim, the time of exposure in a toxic atmosphere, and the degree of carbon monoxide concentration. Clinical material is scarce, and further cases must be reported before a definite conclusion can be reached. So far, 20 patients in coma due to carbon monoxide intoxication have been treated by cytochrome medication after having been given the usual artificial respiration and inhalation of oxygen. Blood-letting and injections of novocaine and of cardiorespiratory analeptics were also used. Cytochrome was given by intravenous injection, in doses of from 15 to 60 mg. of cytochrome C in isotonic sodium chloride solution; the maximum dose at one injection was 30 mg., repeated 15 minutes later when necessary. All the patients revived in from 8 to 30 minutes after administration of the drug, and all survived except two who died later as a result of secondary complications. There were no side-effects except for vomiting in one case. The duration of the coma seems to be shortened by cytochrome treatment; cardiopulmonary conditions improve; and cyanosis disappears quickly.

Survival Rates After Acute Myocardial Infarction with Long-Term Anticoagulant Therapy. J. W. Keyes, E. H. Drake and F. J. Smith. Circulation 14:254-259 (Aug.) 1956 [New York].

Continuous long-term anticoagulant therapy with bishydroxycoumarin (Dicumarol) was practiced at the cardiology division of the Henry Ford Hospital, Detroit, in 121 selected patients with acute myocardial infarction. A group of 234 unselected patients with acute myocardial infarction who had been treated at the same hospital before the use of anticoagulant drugs for this condition and who received the same general medical care as the 121 selected patients served as controls. Both groups were divided into two subgroups, one consisting of patients with a single infarct and one in which the patients had survived the acute phase of two or more well-substantiated episodes of acute myocardial infarction before being placed on therapy. A comparison was made of the death rates of the treated and the control groups with mortality determinations made at six-month intervals for the first two years and then at yearly intervals up to five years. The rate of death in the group with single infarct was three times greater for patients not receiving anticoagulants. In the group with recurrent infarcts the rate of death was five times greater without anticoagulant therapy than with it. Seven new myocardial infarctions occurred among the 121 patients receiving anticoagulant therapy, an incidence of 5.7% The prothrombin time was determined with the Quick two-stage method and was considered adequate in five, unsatisfactory in one, and unknown in one of the seven patients. Twelve deaths (9%) occurred among the 121 treated patients as compared with 112 (48%) among the 234 control patients. Hemorrhage was a contributing cause of death in three of the seven patients in the treated group, although in none was death caused by blood loss alone. Anticoagulant therapy was discontinued in 28 patients who had been started on a long-term program; in 14 patients therapy was discontinued because of hemorrhage, and the other 14 patients discontinued treatment of their own accord. New infarcts occurred in 14 of the 28 patients during a period of from 3 day to 20 months after withdrawal of the anticoagulants. Thus the incidence of acute myocardial infarction among patients discontinuing therapy is high. Six of these 14 infarcts were fatal. One patient had a popliteal embolus after cessation of anticoagulant therapy, and the remaining 13 patients were alive 4 to 54 months after therapy had been discontinued.

In the course of five years of long-term anticoagulant therapy, bleeding occurred 54 times in 51 patients (42.1%). "Serious" or "major" bleeding occurred in 16 patients (13.2%) and minor bleeding in 35 (29%). In view of the time involved, the incidence is not excessive, since the hazard from hemorrhage is considerably less than that from the progress of the disease. Hemorrhagic manifestations do not constitute a contraindication to anticoagulant therapy. A trained anticoagulant team, working with a well-equipped laboratory, is necessary for the success of anticoagulant therapy. Regular weekly prothrombin determinations must be made. Long-term anticoagulant therapy has been particularly effective in patients with recurrent infarcts.

Local Treatment of Arthropathies with High Doses of Hydrocortisone Acetate. Reumatismo 8:214-219 (July-Aug.) 1956 (In Italian) [Milan, Italy].

Fifty-six patients with rheumatic and articular disease were treated with intra-articular injections of hydrocortisone acetate. The doses were considerably higher than usual. In 20 patients with rheumatic arthritis the drug was almost always injected into the knee; the patients were followed for at least one month; results were very good in 17 cases and good in 3. Twenty-seven patients had arthrosis; negative results followed in only two cases. Injections of 5 cc. of hydrocortisone, equivalent to 125 mg. of hydrocortisone acetate, were always well tolerated. The qualitative effect of high doses of the drug is similar to that of low doses of the drug, but the quantitative effects are much better. Results last longer and repetition of the treatment can be avoided. Longer-lasting results were obtained in patients with rheumatic arthritis who were also undergoing treatment with prednisone. Five cases of periarthritis were cured rapidly with one injection, and the results were still good after a month.

The Prevention and Correction of Deformity in Rheumatoid Arthritis. N. Swanson. Canad. M. A. J. 75:257-261 (Aug. 15) 1956 [Toronto, Canada].

Both knees, both elbows, and many finger joints of a 16-year-old boy were painfully swollen due to rheumatoid arthritis. They were immobilized in plaster-of-Paris splints, which prevented all painful movements and so relieved the muscle spasm. The temperature and erythrocyte sedimentation rate fell toward normal, and body weight later rose rapidly. Joint immobilization marked the turning point in the illness and in some way also favorably affected the systemic manifestations. Muscle spasm is the initiating cause of deformity in rheumatoid arthritis. If a splint can act as an artificial spasm-substitute, the physiological spasm, whose fundamental purpose is to fix the joint in slight flexion in order to prevent movement that worsens the pain caused by the inflammatory process, will no longer be necessary and the muscle will relax. In the case of a 65-year-old man, a posterior, nonpadded skin-tight splint of plaster-of-paris was applied to the leg. The left knee was in 45-degree flexion when the splint was applied. At the end of seven days the cuffs were removed. The ankle was lifted up with the thigh remaining inside. For several days afterward, the leg was lifted out for exercise only and then replaced in the splint with a bandage instead of the cuffs to restore the immobile state. The exercises

The place of publication of the periodicals appears in brackets preceding each abstract.

Periodicals on file in the Library of the American Medical Association may be borrowed by members of the Association or its student organization and by individuals in continental United States or Canada who subscribe to its scientific periodicals. Requests for periodicals should be addressed "Library, American Medical Association." Periodical files cover 1947 to date only, and no photoduplication services are available. No charge is made to members, but the fee for others is 15 cents in stamps for each item. Only three periodicals may be borrowed at one time, and they must not be kept longer than five days. Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

included gentle flexion a few times only each day. After another four days a fresh splint was made with the same technique, with the leg in the new position in order to consolidate the gain made. The leg was nearly straight when the second cast was removed after an additional week.

Not only knee joints but also hand deformities lend themselves to correction readily by correctly applied light splints. Two cases, one of a 51-year-old man and one of a middle-aged woman, illustrate the improvement which took place in their hands, with increased range of flexion and extension of the fingers obtained by wearing light, comfortable splints continuously at first and later intermittently. Splints are a valuable and often essential part of the treatment of rheumatoid arthritis, especially when a joint is acutely and painfully swollen; when muscle spasm about a joint is producing deformity; and when subluxation has impaired function, which could be improved if the extremity or a part of it were held in a better position.

A Clinical and Pathological Study of Sixteen Cases of Rheumatoid Arthritis with Extensive Visceral Involvement ("Rheumatoid Disease"). R. J. G. Sinclair and B. Cruickshank. Quart. J. Med. 25:313-332 (July) 1956 [Oxford, England].

Patients who have arthritis of the rheumatoid type may have involvement of tissues other than the joints. Three types of lesions have been described in previous accounts of systemic involvement: granulomas, nonspecific inflammation, and amyloidosis. This report is concerned with clinical and pathological data on 16 patients with widespread systemic involvement. Thirteen of the patients were women and three were men. The main lesions found were granulomas in the heart (five cases) and elsewhere (two cases), arteritis (nine cases), pleurisy (seven cases), splenomegaly (four cases), lymphadenopathy (four cases), lymphorrhages in muscles and nerves (nine cases), and amyloidosis (four cases). Rheumatoid endocarditis was present in eight patients, with clinical evidence in seven. Some combination of myocarditis, coronary arteritis, or pericarditis was present in another five patients, all of whom showed clinical features of cardiac involvement. Pleurisy had occurred in 12 patients, in 7 of whom no etiological factor could be found. Further evidence is presented to show that unexplained pleurisy is very common in rheumatoid arthritis.

Amyloidosis is regarded as a systemic manifestation of the disease. The visceral lesions of rheumatoid arthritis were the main cause of death in eight patients and a major contributory factor in another seven patients. None of the lesions was considered to be the result of treatment. The term rheumatoid arthritis refers to a nonspecific lesion confined to the joints. It is suggested that cases in which other tissues are involved should be called rheumatoid disease. The authors regard it as unfortunate that rheumatoid disease and arthritis of rheumatoid type have been included under the heading "collagen diseases," for the evidence at present available does not justify this step. All the lesions of rheumatoid disease affect mesodermal or connective tissues, but it is not possible to pick out a common basic change in all the different sites. Although many of the changes are nonspecific, they occur often enough to be regarded as part of the disease. There are differences of opinion about the part played by collagen in the granuloma of rheumatoid disease and about the composition of the fibrinoid material that is one of its main features. It does not seem possible that all the lesions of the disease can be explained on the basis of a primary abnormality of collagen.

The Rash of Rheumatoid Arthritis and Still's Disease. I. C. Isdale and E. G. L. Bywaters. Quart. J. Med. 25:377-387 (July) 1956 [Oxford, England].

Isdale and Bywaters believe that the rash that may occur in rheumatoid arthritis and in Still's disease (multiple rheumatoid arthritis affecting children and marked by enlargement of lymph nodes, particularly of the spleen and by irregular fever), has received insufficient attention. Although it is usually considered infrequent, in the experience of these authors it is not uncommon, and, since it is easily recognizable, it has proved of great diagnostic value, particularly in early cases without arthritis. The authors surveyed 166 cases of Still's disease seen in the Canadian Red Cross Memorial Hospital in the last 7 years and over 500 cases of rheumatoid arthritis seen at the Postgraduate Medical School of London during the last 15 years. In all cases designated as Still's disease the condition had started before the 16th birthday. The diagnosis in all cases was based on the presence or development of polyarthritis of the rheumatoid type affecting a number of joints, or, in juvenile cases where less than four joints were involved, on synovial biopsy showing characteristic rheumatoid changes. The characteristic rash consists of small macular lesions, 3 mm. or less in diameter, with a slightly irregular margin. Larger lesions may sometimes occur and may show central pallor. Less commonly the rash may appear confluent over areas up to 5 cm. in diameter. It may be slightly raised, especially when it first appears, but does not itch. Such papules usually become flattened, but occasionally small ringed areas with slightly raised margins may be seen. The rash is bright salmon-pink in color: it is usually surrounded by a narrow areola of normal skin that is paler than its surroundings. Lesions occur most frequently on the limbs and over the trunk, less often on the face and neck.

This rash occurred in 46 (27.7%) of 166 children with Still's disease. It was also observed in 7 of more than 500 adults with rheumatoid arthritis. The rash is frequently associated with intermittent fever, splenomegaly, lymphadenopathy, and other signs of activity of the disease, particularly a raised sedimentation rate. It is transient, appears towards evening and with high temperatures, and does not spread. It may last, on and off, for a week or for many years. It appears usually within two weeks of the onset of the disease or may precede other manifestations by a period ranging from six months to three years. Histologically it is characterized by a sparse infiltrate of polymorphonuclear cells in the subepithelial layer. The effects of various local procedures were tried on the rash. The application of hydrocortisone ointment twice daily was ineffective. Intracutaneous injection of isotonic solution of sodium chloride was likewise ineffective, but local injection of hyaluronidase inhibited the formation of the macules.

ABO Blood Groups and Gastro-Duodenal Diseases. B. P. Billington. Australasian Ann. Med. 5:141-148 (May) 1956 [Sydney, Australia].

The investigations reported here were undertaken to ascertain whether the associations of gastroduodenal diseases and ABO blood groups were as valid for Australia as for the United Kingdom. Records of public inpatients at a Sydney hospital were analyzed during the period 1947 to 1954. As blood grouping is not performed on all inpatients, only those cases in which data were available by virtue of transfusion for bleeding or surgical intervention could be admitted to this series. No immigrants were included. The author was able to adduce evidence that there is an association between chronic duodenal ulcer and blood group O, but no significant difference in the ABO blood group distribution was found between controls and patients with chronic gastric ulcer taken as a whole. Patients with chronic gastric ulcer may be divided into two significantly different populations with regard to ABO blood group distribution according to the site of the ulcer. To a degree differing significantly from that found in a control population, prepyloric ulcer appears to be associated with blood group A and nonprepyloric ulcer with group O. Carcinoma of the stomach in this small series was not found to be associated with blood group A, as had been observed in Britain. Patients with carcinoma of the stomach can also be divided into two significantly different populations with regard to ABO blood group distribution according to the site of origin of the neoplasm. To a degree differing significantly from that found in a control population, prepyloric carcinoma appears to be associated with blood group A and nonprepyloric carcinoma with blood group O. The association between carcinoma of the stomach and blood group A found in Britain may be explained by a higher proportion of prepyloric carcinoma there than in the present series.

Association between chronic gastric ulcer and gastric carcinoma and the ABO blood groups appears to be governed in part by the site of lesion, prepyloric lesions being associated with blood group A and nonprepyloric lesions with blood group O, irrespective of the nature of the lesion. There is no explanation for the association between ABO blood groups and gastroduodenal disease. It seems possible that gastric mucous secretions may be more important than gastric parietal (acid) secretions in such associations. If ABO blood groups are associated with gastric resistance or susceptibility factors, and if a relationship to a single gene is involved, then it would appear from this small series that an association with blood group gene O is more likely to be implicated with protection of the prepyloric mucosa to both ulcerogenic and carcinogenic factors.

Chronic Cough: Analysis of Etiologic Factors in a Survey of 1,274 Men. A. M. Phillips, R. W. Phillips and J. L. Thompson. Ann. Int. Med. 45:216-231 (Aug.) 1956 [Lancaster, Pa.].

A study of 1,274 men was carried out in an attempt to determine the incidence of chronic cough. For analytical purposes, the men studied were divided into two groups between which there were geographical, residential, and occupational differences. Group 1 was composed of 974 men employed in a large steel-making plant in West Virginia, and group 2 consisted of 300 male patients chosen at random from the medical and surgical wards of the Veterans Administration hospital in Providence, R. I. The men in group 1 worked in and most of them resided in or near a single, highly industrialized urban community in which the general air environment contained considerable dust and smoke. Two hundred ninety-seven (31%) of the 974 men had chronic cough. The 300 in group 2, from which patients with specific pulmonary disease, congestive heart failure, and advanced terminal disease were excluded, lived in scattered areas of New England, including rural and urban communities with none or only mild air pollution. One hundred thirty-two (44%) of the 300 men had chronic cough. Thus 429 (34%) of the total of 1,274 men gave a history of chronic daily cough with sputum. The findings failed to show that residence in a generally more polluted urban atmosphere leads to increased incidence of chronic cough.

In addition to the general environmental factors, those of previous pulmonary infection, smoking habits, and age were evaluated. Correlation was found between cigarette smoking and chronic cough. This was shown by the direct effect of the quantity of cigarettes smoked daily, the cessation of cough in the men who stopped smoking, and the striking increase in cough with age in the smokers. No direct correlation was seen with any of the other factors except age, and this was of importance chiefly in those who smoked cigarettes. It is suggested that, in view of these findings, certain factors such as industrial exposure, commonly considered as important in causing chronic cough and bronchitis, may need reevaluation. Comparison between smokers and nonsmokers would seem to be an integral part of such studies. The high incidence of chronic cough in the older age group of cigarette smokers, together with its duration, may well be related to structural changes in the lungs of such persons. The development of chronic bronchitis secondary to inhalation of cigarette smoke deserves consideration as the most common cause of pulmonary emphysema.

A New Intra-Arterial Treatment of Arterial Diseases of the Lower Extremities. P. Šnábl, Z. Fiala and F. Polak. Ztschr. ges. inn. Med. 11:660-665 (July 15) 1956 (In German) [Leipzig, Germany].

The intra-arterial administration of drugs in the treatment of arteriosclerotic disorders has the advantage of producing, even with the administration of relatively small doses, a comparatively high concentration at the site of action. The authors report their experiences with the following: (1) procaine hydrochloride in a dose of 10 ml. of a 1% solution; (2) nicotinic acid with ethanol amine (Neopeviton) in a dose of 5 or 10 ml.; (3) heparin in a dose of 5,000 anticoagulation units; and (4) tetraethylammonium bromide (TEAB) in a dose of 3 to 10 ml. The drugs were given daily by injection into the femoral artery. A course of treatment consisted of either 15 to 20 or 20 to 30 injections. Each drug was studied in six patients and its evaluation was based on the claudication test and on the temperature and color of the skin. The number of steps the patient was able to take before and after treatment during the claudication test provided a quantitative indicator for the therapeutic effect and could be statistically evaluated. The other criteria were suitable only for qualitative analysis. All the data indicated that tetraethylammonium bromide was much more effective than the control drug procaine hydrochloride, and the other drugs had usually about the same effect as procaine hydrochloride. Since the injections of tetraethylammonium bromide into the femoral artery were well tolerated and since, unlike intravenous injection, intra-arterial injection of this drug did not reduce the blood pressure excessively, the authors feel that the intrafemoral administration of tetraethylammonium bromide can be recommended for the treatment of obliterative disorders of the lower extremity.

Indications for Hydrocortisone and Prednisone Treatment of Progressive Pulmonary Tuberculosis: Four Years' Experience with 70 patients. G. Favez and F. Aguet. Schweiz. med. Wchnschr. 86:843-851 (July 28) 1956 (In French) [Basel, Switzerland].

Extensive progressive pulmonary tuberculosis with predominantly pneumonic foci, recent in appearance, and acute miliary tuberculosis call for treatment with hydrocortisone and prednisone in combination with antibiotics. Prednisone gives better results. Resorption of the parenchymal opacities is remarkable, and so is the steady improvement in general health. Corticotherapy, which is only an initial treatment, should be followed by continual antibiotic and bacteriostatic therapy. However, the therapeutic effects of adrenal hormones are not sufficiently well known, and the side-effects are not so slight as to justify inclusion of cortisone medication in the usual therapeutic pattern in tuberculosis. Tuberculous meningitis constitutes another indication for cortisone therapy. A careful study of the patient and the efficient prophylaxis provided by antibiotics make possible the employment of similar preparations in acute cases.

Twenty patients with pneumonic tuberculosis with extensive onset were improved clinically and radiologically during treatment with hormones. Many of them would have died without the help of cortisone therapy. The first to be treated, who were the most seriously affected, have been able to return to their work. Two years have elapsed and symptoms have not reappeared.

Acute Gastritis as the Cause of Otherwise Unexplained Upper Gastrointestinal Hemorrhage. E. L. Posey Jr. and S. L. Stephenson Jr. Am. J. Gastroenterol. 26:137-149 (Aug.) 1956 [New York].

Acute gastritis is a not infrequent cause of gastrointestinal

The behavior of acute gastritis with hemorrhage differs completely from that of chronic gastritis. The exogenous agent, be it alcohol or an allergen, apparently produces a sudden violent mucosal reaction with congestion, erosion, and hemorrhage, which heals without residual symptoms in a few days' time. None of these patients died, and not a single case of fatal hemorrhage from gastritis has been found in the literature. Apparently this condition is essentially a benign disorder, even though the blood loss may be severe.

Clinical Experience with Streptomycin of "Reduced Toxicity" (Streptothenat) in Treatment of Tuberculosis. G. Jaccard and T. Becht. Schweiz. med. Wchnschr. 30:862-864 (July 28) 1956 (In German) [Basel, Switzerland].

Forty-one patients with pulmonary tuberculosis, three with tuberculous pleurisy, and two with tuberculous meningitis were given intramuscular injections of streptothenat, a mixture of 80% of streptomycin sulfate and 20% of streptomycin pantothenat. Most of the patients were given injections of 1.5 or 2 gm. of streptothenat two or three times a week; they had no local pain, and only 10 patients had dizziness or headache. Thirteen patients who were given 3 or 4 gm. of the drug twice a week had toxic side-effects consisting of damage to the vestibular nerve.

Streptothenat was given a trial in this small number of patients in an attempt to determine whether this compound, which exerts the same tuberculostatic effect as streptomycin, can be given in higher doses than streptomycin sulfate without causing undesirable side-effects. The clinical experiences in the 46 patients and determinations of the concentration of streptothenat in the blood of 11 of these patients suggest that strepothenat can be given in larger doses than streptomycin sulfate, provided that intermittent treatment with doses of 1.5 or 2 gm. two or three times a week is practiced for three months. Because of the general tendency to give tuberculostatic therapy for one year or longer, one should at present continue the streptothenat therapy after three months with smaller doses until additional experience has been gained. The number of patients is too small and the follow-up period too short to evaluate the therapeutic effect of the doses employed.

SURGERY

Status of Fifty Patients Four and a Half to Seven Years After Mitral Commissurotomy. O. H. Janton, J. C. Davila and R. P. Glover. Circulation 14:175-184 (Aug.) 1956 [New York].

The authors report a follow-up on the first 50 patients who underwent mitral commissurotomy four and a half to seven years ago. There were 36 women and 14 men. At the time of the intervention the patients were between the ages of 17 and 47 years. Before their admission to the hospital for the operation 20 patients had a rheumatic infection, 23 had hemoptysis, and 27 had one or more attacks of congestive heart failure. On admission, 13 patients had chronic congestive heart failure and 19 had permanent atrial fibrillation. Three patients died in the course of the first postoperative month, representing an operative morality of 6%; death in one who died two hours after the operation was apparently caused by operative and anesthetic shock, one died of acute cardiac failure, and one of excessive mitral insufficiency. Six patients with extensively calcified valves died within a period of from six weeks to three years after commissurotomy, thus representing a late morality of 12%. Irreversible cardiopulmonary, hepatic, and renal disease at the time of the surgical intervention was responsible for the deaths of three of these patients; two patients had inoperable valves that precluded successful commissurotomy, and in one patient preexisting mitral insufficiency was aggravated by the operation.

Thus 41 patients (82%) were living at the time the paper was written, and clinical findings, electrocardiographic tracings, teleroentgenograms, and catheterization data obtained from these patients were evaluated. Only 4 of the 41 patients had no murmurs on follow-up examination; 11 did not have their original mitral diastolic murmur and 14 had mitral systolic murmurs of varying intensity that were not present preoperatively. Definite conclusions regarding the present clinical status of these patients could not be reached from their murmurs alone. Patients with "pure" mitral stenosis obtained the best results from mitral commissurotomy. Although the electrocardiographic changes after surgery did not regularly show conclusive evidence of improvement, there was a small group of patients in whom postoperative regression of right ventricular hypertrophy occurred. Fluoroscopic and teleroentgenographic studies revealed that in 44 patients (87%) the size of the heart was the same as or smaller than before the surgical intervention, whereas in the years preceding the operation the size of the heart had grown progressively larger. The available cardiac catheterization data paralleled and corraborated the observed functional state of the patients. Twenty-one patients (51%) without valvular calcification showed greater improvement than the 20 patients (49%) with valvular calcification. Evidence of rheumatic activity was observed in the course of the postoperative period in eight patients (19.5%). Valvular stenosis was not observed in the 41 living patients nor in those who died during the postoperative period. An embolus occurred in only one patient during the operation, and that patient recovered almost completely. There were no postoperative emboli. Twenty-nine (71% of the living patients or 58% of the original 50 patients) were in better condition and living a more nearly normal life than they were before the operation. Commissurotomy confers a genuine, often dramatic, and usually persistent benefit on the patient.

Congenital Cirsoid Aneurysm of a Coronary Artery with Associated Arterio-Atrial Fistula, Treated by Operation: A Case Report. H. E. Mozen. Ann. Surg. 144:215-217 (Aug.) 1956 [Philadelphia].

A case of congenital cirsoid aneurysm of the left coronary artery associated with an arterioatrial fistula in a 10-year-old boy is described. Except for slight dyspnea on extreme exertion, the child was asymptomatic. The blood pressure varied between 120/80 and 130/60 mm. Hg. The pulse rate was 84 per minute. The size of the heart was normal. A loud, continuous, to-and-fro murmur with systolic accentuation was heard in the pulmonic area. A lower-pitched systolic murmur was also heard at the apex. There was questionable diminution of the peripheral pulmonary vascular markings. Cardiac catheterization was performed and was technically satisfactory. Pressures and oxygen concentrations in the pulmonary artery, right ventricle, right atrium, and venae cavae were normal. When the pericardium was opened, a tremendously dilated and tortuous vessel was found overlying the interventricular septum in the usual location of the anterior descending branch of the left coronary artery. In many places, large branches disappeared abruptly into the myocardium of the left ventricle. One branch, which was 1.5 cm. in length and 0.5 cm. in diameter, appeared to empty directly into the left atrium. Compression of this vessel obliterated the harsh thrill. Evidently this was a fistula that was carrying large amounts of blood from the high-pressure aneurysm into the low-pressure left atrium. The fistula was doubly ligated. The aneurysm immediately became smaller in diameter, and the thrill disappeared completely. The postoperative course was uncomplicated. The murmurs disappeared, and the heart sounds became normal and remained so.

The case described is the 52nd instance of an aneurysm of a coronary artery to be reported. It is the first case in which the diagnosis was made at operation; in the other 51 cases the diagnosis was made at autopsy. This is also the first case in which an associated arterioatrial fistula has been cured by operation. The possibility of making a correct preoperative diagnosis is considered.

Stump Recurrence and Total Thyroidectomy in Papillary Thyroid Cancer. F. F. Rundle and A. G. Basser. Cancer 9:692-697 (July-Aug.) 1956 [Philadelphia].

Stump recurrence in the sense of recurrent carcinoma in the fragment of thyroid gland remaining after incomplete lobectomy must generally be regarded as due to a surgeon's failure. There has been an insufficiently wide extirpation of a growth that is only locally malignant. The authors describe two cases of papillary thyroid cancer with multiple foci in a 34-year-old man and in an 18-year-old girl that illustrate the pathological aspects that have a practical bearing on surgical treatment. Multiple foci are virtually confined to the papillary and to the mixed papillary and follicular growths occurring in young people. These multiple foci may represent seedlings resulting from intraglandular lymphatic spread rather than separate primary foci. The satellite foci may be microscopic in size and separated from the obvious nodule by apparently normal thyroid tissue several centimeters in thickness. The foci may be bilateral as well as small in size. Spread from a tumor in one lobe may occur to the contralateral cervical lymph nodes. The juxtathyroidal nodes, including the pretracheal nodes above and below the thyroid isthmus, those around the thyroid veins, and those in the tracheoesophageal groove, in contrast to the lateral cervical nodes, lie on or near the vital structures of the trachea and the esophagus, and it is therefore highly desirable that they be removed while their invasion is still microscopic in extent. With the lateral cervical nodes, however, a policy of "wait and see" seems permissible.

Potentially the most serious invasion is that occurring medially and posteriorly. Medial extension occurs most commonly to and through the wall of the trachea, between the cartilaginous rings. Thence spread occurs upward and downward in the submucous layer of the trachea, forming an intraluminal growth that heaps up, leading to obstruction, ulceration, and hemorrhage. Spreading posteriorly, papillary growths involve structures in the tracheoesophageal groove, the recurrent nerve, prevertebral muscles, and spinal nerves, and even invade the spinal canal, as happened three and a half years after a "thyroidectomy" in a third patient, a 24-year-old woman. Heavy postoperative irradiation with a dose of 3,500 r led to widespread skin atrophy and dense sclerosis of all the tissues at the root of the neck; it masked, and ultimately precluded excision of, the subsequent stump recurrence. Anything short of complete extrafascial thyroidectomy with resection of the juxtathyroidal nodes may, therefore, be followed by a recurrence at the thyroid site. A plea is made for the general use of frozen sections when operating on suspicious thyroid nodules. The routine use of "prophylactic" deep roentgen-ray therapy after operations for papillary cancer is disadvantageous and should be abandoned.

Congenital Aortic Stenosis: Clinical Aspects and Surgical Treatment. D. F. Downing. Circulation 14:188-199 (Aug.) 1956 [New York].

Twenty-nine male and eight female patients between the ages of 4 months and 39 years with congenital aortic stenosis were studied. Fatigue, shortness of breath, and profuse perspiration were the commonest symptoms. Central nervous system manifestations and chest pain were infrequent. A loud, harsh systolic murmur in the second and third right interspaces near the sternal border was observed in all the patients, and in 19 it was accompanied by a systolic thrill. These physical signs are of great diagnostic significance because they are rarely found in this location in patients with other malformations. On roentgen-ray examination the most frequent manifestation was dilatation of the ascending aorta. Electrocardiographic evidence of left ventricular hypertrophy was found in 22 patients. Catheterization of the right side of the heart was completed in 31 patients, simultaneous catheterization of the left and right sides of the heart was done in one, and in another the right and left sides were catheterized at different times. Catheterization of the right side of the heart proved to be helpful in ruling out other lesions. Catheterization of the left side of the heart was diagnostic in a patient in whom a gradient in systolic pressure across the valve was demonstrated. Differentiation of valvular from infundibular stenosis was not possible.

Relief of severe obstruction is mandatory because of the danger of sudden death. A satisfactory procedure is available for correction of valvular stenosis. It involves the dilatation of the narrowed orifice by an instrument inserted into the left ventricle. This operation was performed on 10 children, 2 of whom were less than 3 years of age, and on 9 adults. There is no optimal age for the surgical intervention; there is only the age of opportunity. There was one operative death, which resulted from irreversible cardiac failure in a 36-year-old man; in addition, an 18-year-old patient died eight months after the operation. One patient with infundibular stenosis was a therapeutic failure. In the remaining 16 patients there was objective evidence of improved flow across the aortic valve. Symptoms were improved in 14 patients, one had had no symptoms preoperatively but had been in cardiac failure in early life, and symptoms became worse in one patient who did not receive proper postoperative care. Although it is too early to judge the results, all but two of the surviving patients appear to have been helped.

Congenital Intrinsic Duodenal Obstruction: Report of 32 Cases. T. C. Moore. Ann. Surg. 144:159-164 (Aug.) 1956 [Philadelphia].

A statistical review is presented of 32 cases of congenital intrinsic duodenal obstruction in 17 baby boys and 15 baby girls (30 white and 2 Negro), 21 of whom were operated on at the department of surgery of the Indiana University Medical Center between 1942 and 1956. Symptoms of complete obstruction from birth were observed in all infants with atresia and in one-half of those with stenosis. Atresia was found more frequently in proximal duodenal obstruction, whereas a distal lesion was more likely to be a stenosis. A plain roentgenogram of the abdomen is regarded as the most reliable single diagnostic measure. Eight (25%) of the 32 infants were premature. Additional congenital malformations were discovered in 13 infants (41%). Duodenojejunostomy was performed in 15 patients, gastrojejunostomy in 5, and duodenoduodenostomy in one. Eighteen (86%) of the 21 infants operated on recovered and 3 (14%) died. Two of the three who died were premature and had additional congenital anomalies.

Bronchogenic Carcinoma with in Situ Carcinoma in the Opposite Lung: Report of Five Cases. R. F. Ryan and J. R. McDonald. Proc. Staff Meet. Mayo Clin. 31:478-485 (Aug. 22) 1956 [Rochester, Minn.].

Ryan and McDonald studied autopsy specimens from 39 men from whom one lung had previously been removed for squamous-cell carcinoma. In all cases the bronchial epithelium of the remaining lung appeared normal on gross examination. Yet when sections were taken from these "good" lungs and examined microscopically, extensive changes in the bronchial epithelium were found. In five cases definite areas of in situ carcinoma of the squamous-cell variety were found. The authors believe that these lesions represent new foci of malignant degeneration and not metastatic disease. While these changes were more pronounced in the main-stem bronchi, similar changes were also found in the tertiary bronchi, as demonstrated in one of the five cases. It is difficult to know how significant these in situ lesions in the opposite lung may be, but it can be assumed that some patients who obtain poor results from operation actually may have new lesions rather than extension, recurrence, or metastasis from the primary lesion. Since the contralateral in situ lesions are multicentric and may have a long latent period, the finding of an in situ lesion at the coryna on bronchoscopic biopsy might not be a valid contraindication to operation if the primary lesion is otherwise operable.

GYNECOLOGY & OBSTETRICS

Defective Blood Coagulation Associated with Intrauterine Foetal Death. J. M. Farrar. M. J. Australia 2:65-68 (July 14) 1956 [Sydney, Australia].

Moderate or severe concealed accidental hemorrhage, long-standing intrauterine fetal death, amniotic fluid embolism, and tumultuous labor are possible precursors of a clotting defect. The coagulation defect in the above conditions may be due to various abnormalities, but the most important are diminution in amount or absence of the blood fibrinogen (hypofibrinogenemia or afibrinogenemia) or the presence of an active fibrinolysin. Hypofibrinogenemia and fibrinolysis may occur separately or together. Hypofibrinogenemia in most instances is probably due to excessive utilization of the circulating fibrinogen or to its destruction by fibrinolysin. Excessive utilization of fibrinogen may occur in the presence of severe hemorrhage associated with fibrinolysis because the clots are immediately dissolved. Fibrinogen levels in the blood may be low in the absence of hemorrhage when the circulation is flooded with material rich in thromboplastin (liquor amnii or products of placental degeneration or damage), because coagulation is initiated and a film of fibrin is deposited on the vascular endothelium. The total quantity of circulating fibrinogen in the body amounts to from 8 to 12 gm., and a 500-cc. blood transfusion may increase the level of fibrinogen by 10 to 20 mg. per 100 cc. The liver can replace the lost fibrinogen rapidly, and in the less severe cases the fibrinogen may be kept above the critical level by regeneration with or without blood transfusion. This may be impossible in the more severe cases, and it is in them that the intravenous administration of fibrinogen may be life-saving.

Intrauterine fetal death assumes a new importance now that it is recognized that it may be associated with impaired coagulation of the blood. The author presents the history of a woman in whom a coagulation defect was associated with longstanding retention of a dead fetus in utero. During her first pregnancy (in 1949) she had had a miscarriage at three months. The second and third pregnancies in 1950 and 1952, respectively, ended with the delivery at term of a macerated fetus that had been dead for one month. No maternal anti-Rh agglutinins were detected. In the present pregnancy fetal movements ceased during the 23rd week. Labor was induced by a drip administration of pitocin after intrauterine retention of a dead fetus for 11 weeks. Contractions had been present for three hours when it was found that blood escaping from the vagina did not clot. When blood was collected for testing an unstable clot formed, which redissolved in 15 minutes. An increased rate of blood loss followed the expulsion of the fetus one and a half hours after the initial hemorrhage. The total blood loss was estimated at two liters. Two and a half liters of blood (containing an estimated 4.5 gm. of fibrinogen) and 4 gm. of fibrinogen were given. The patient was discharged from the hospital on the seventh day.

Vulvovaginitis as Complication in Antibiotic Therapy. K. Bjøro. Tidsskr. norske lægefor. 76:479-480 (July 1) 1956 (In Norwegian) [Oslo, Norway].

A case of postpartum vaginal moniliasis with severe exacerbation during and after treatment with Aureomycin is reported. The patient's husband was also infected with moniliasis. Local treatment with Nystatin, an antibiotic derived from Streptomyces noursei, proved effective. Candida albicans is frequently part of the normal vaginal flora, most often in pregnancy and directly after delivery, and the danger of promoting its growth by the use of antibiotics, especially those of the tetracycline group, is emphasized.

Congenital Adrenal Hyperplasia (Pseudohermaphroditism) Before and After Cortisone Therapy: I. Adolescent Development and Menstruation. E. K. Smith and R. R. de Alvarez. Am. J. Obst. & Gynec. 72:404-415 (Aug.) 1956 [St. Louis].

A case of congenital adrenal hyperplasia is described in a 16-year-old girl with the chief complaint of amenorrhea. Physical examination showed a typically female-appearing girl with a husky, almost masculine voice. The arms and thighs were unusually hairy, and the breasts were hypoplastic and undeveloped. There was a marked hypertrophy of the clitoris. A tiny uterus and both ovaries were palpated; the uterus seemed to be normal in shape and mobility and the ovaries were normal in size. On exploration of the abdomen, the uterus, tubes, and ovaries were plainly identified. The hypertrophied clitoris was excised and a perineotomy was performed. The wounds healed satisfactorily.

After a control period during which 17-ketosteroids, estrogens, gonadotropins, and pregnanediol excretions were determined weekly and body temperature and vaginal cytology were determined daily, cortisone therapy was started with 50 mg. given daily for 60 days. The output of 17-ketosteroids ranged between 40 and 50 mg. during the control period before cortisone was given. A prompt decrease in 17-ketosteroid excretion to 7.5 mg. resulted on the fourth day of treatment. The authors agree with Wilkins that for optimum effect the dose of cortisone should be adjusted to keep the excretion of 17-ketosteroids below 8 mg. daily. It remained below 8 mg. for about 23 days, then rose to levels of 20 or 30 mg., which were maintained for over three months despite the steplike increase in cortisone dosage. Only by the intramuscular administration of 50 mg. of cortisone daily for one week could the excretion of the 17-ketosteroids be decreased to below 8 mg. daily. The oral administration of 100 mg. of cortisone daily was required to maintain the level of 17-ketosteroid excretion at 8 or 10 mg. daily. The oral dose of cortisone and the 17-ketosteroid excretion were maintained at these levels for about six months. At this dosage considerable feminization occurred, with normal development of breasts, cornification of the vaginal smear, regular menstruation, and a decrease in hirsutism. Although the urinary estrogen excretion and the cornification of the vaginal smear showed cyclic changes coinciding with the menstrual periods, no positive evidence of ovulation was obtained during the period of study.

The primary defect in congenital adrenal hyperplasia is the inability of the adrenal cortex to synthesize readily the glucocorticoids, such as hydrocortisone. This defect causes excretion of excessive amounts of corticotropin by the anterior pituitary, to which the adrenal cortex responds by the production of an increased amount of androgenic steroids, resulting in the symptoms of virilism. The excessive secretion of androgens and estrogens suppresses the gonadotropic function of the anterior pituitary. Administration of cortisone inhibits the excessive output of corticotropin, thereby decreasing adrenal secretion of androgen and permitting gonadotropic activity by the pituitary, ovarian secretion of estrogen, and normal actions of estrogens on secondary sex development.

Afibrinogenemia Resulting from Amniotic Fluid Infusion. H. F. Sandmire and B. M. Covalesky. U. S. Armed Forces M. J. 7:1351-1355 (Sept.) 1956 [Washington, D. C.].

Studies in patients with amniotic fluid embolism revealed that patients who survived the initial shock died with hemorrhagic manifestations. Bleeding occurred from the mucous membranes, organ surfaces, and vagina, and the blood at autopsy was liquid. Investigation into the hemorrhagic tendencies of amniotic fluid embolism revealed thromboplastin in the amniotic fluid. The concentration of thromboplastin in amniotic fluid is apparently determined by the degree of fetal exfoliation and is hence variable from patient to patient. Death occurring suddenly in amniotic fluid embolism can be explained by extensive intravascular coagulation, while death occurring two or three hours after delivery is due to postpartum hemorrhage resulting from afibrinogenemia. The available circulating fibrinogen is rapidly used up in the formation of the intravascular clot, and hence afibrinogenemia or hypofibrinogenemia results. Two possible methods of entry of amniotic fluid into the maternal circulation have been suggested. One portal of entry is thought to be through the exposed endocervical veins, which become lacerated during normal labor. The second portal of entry involves a rupture of the membranes somewhere in the upper segment of the uterus, with eventual escape of the fluid through the uteroplacental site.

The authors cite the history of a patient who, they believe, had afibrinogenemia as a result of the entrance of amniotic fluid into the maternal circulation. Postpartum oozing became ominous and responded only temporarily to blood transfusions, but was finally controlled by the intravenous administration of fibrinogen. The authors stress the importance of having fibrinogen available, inasmuch as obstetric hemorrhage is still an important cause of maternal deaths.

PEDIATRICS

Viral Infections in the Embryo. J. M. Adams, H. D. Heath, D. T. Imagawa and others. A. M. A. J. Dis. Child. 92:109-114 (Aug.) 1956 [Chicago].

Experiments were carried out in mice in an attempt to confirm the concept that viral infections of the mother during gestation may adversely affect the developing young. The concept suggests that severe infections in the embryo may result in death, while mild infections may produce abnormalities or the fetus may be born apparently normal. Swiss albino mice were inoculated with a human strain of influenza virus just after mating. When the animals were killed at approximately 18 days of gestation, 168 live embryos were present in 20 mice of the virus-infected group, as opposed to 190 live embryos in 20 control animals. In the virus-infected group there were 10 dead embryos and in the controls there were 5 dead embryos. Among the 10 dead embryos, 2 were smaller than normal, 1 was curled and shorter than normal, 2 showed abnormalities in the cephalic area, and 5 were resorbed. Among the five dead controls, one was small, one was normal, and three were resorbed. No true anomalies or abnormalities were observed in the control group. Thus not only was the pregnancy rate reduced but evidence of abnormalities in the fetuses was increased by inoculation of the mother animals with the influenza virus.

Embryonated hen's eggs that had been incubated for 48 hours were injected with influenza-A virus through the vitelline membrane immediately covering the embryo. The appearance of the body flexion and microencephaly was characteristic of influenza infection 24 hours after the inoculation. After 48 hours the mesencephalon and telencephalic hemispheres were typically almost completely collapsed. The eyes were frequently flattened and misshapen, and the auditory vesicles sometime appeared compressed. Microscopic sections of the infected embryos revealed a distorted and abnormal spinal cord, and the amniotic membranes were thin and flattened. Embryos that received noninfected allantoic fluid developed normally. Virus was recovered from all of the suspensions prepared from dead embryos with typical anomalies. Dilutions of antiserum as high as 1:800 completely protected all embryos against both the teratogenic and the lethal effects following infection after mixture with the virus in vitro. This result did not occur when either normal rabbit serum or control medium was substituted for immune serum. The optimum protection was obtained when antiserum was administered before virus inoculation. The protective effect was less marked when immune serum was given one, two, or five hours after virus infection, and it practically disappeared when serum therapy was delayed until eight hours after virus injection. A 100% incidence of anomalies and death occurred in the control group.

Neonatal Nephritis. L. I. Taft. Australasian Ann. Med. 5:113-117 (May) 1956 [Sydney, Australia].

A survey of 1,200 autopsies, performed at the Royal Children's Hospital in Melbourne from 1949 to 1954, was made in order to determine the incidence and nature of neonatal glomerulonephritis. The histories and pathological findings in two infants (one boy and one girl) in whom the diagnosis of neonatal glomerulonephritis could reasonably be entertained are reported. Both infants were hospitalized when three weeks old, one because of intermittent diarrhea and the other because of vomiting. The clinical manifestations of renal failure in infancy are usually gastrointestinal in type, and antemortem diagnosis of glomerulonephritis is made on the results of laboratory investigations of the urine and serum. This was exemplified by observations on the first infant. The renal origin of the symptoms was suspected in the second infant. Death occurred in the first infant 67 days and in the second 14 days after admission to hospital.

Autopsy in each infant revealed shrunken kidneys with structural deformity, cystic changes, and scarring. The histological appearance resembled that of glomerulonephritis, showing parenchymal damage, cellular infiltration, proliferative phenomena, and fibrosis. Increased cellularity of the tufts, capsular exudate, and adhesions were seen in the glomeruli, with red blood cells and casts in the tubules. Tuft digitation and capillary obliteration had progressed to hyalinization of many glomeruli. Islands of dilated subcapsular tubules were lined by hypertrophic or flattened cells, while other tubules were shrunken and lined by irregular atrophic epithelium. The number of nephrogenic tubules seen indicates that increased nephrogenesis continued after term, probably under the stimulus of renal failure. These and other cases reported in the literature suggest that the disease process is initiated in utero and that the pathogenesis is comparable to that observed in glomerulonephritis in later life, modified by the developmental processes taking place in the kidney at that time. In the same period in which these two cases were discovered, pyelonephritis associated with urinary tract anomalies and/or septicemia was found in 49 babies that had died within the first year of life.

Penicillin V Treatment of Beta-Hemolytic Streptococcal Infections in Children. B. B. Breese and F. A. Disney. A. M. A. J. Dis. Child. 92:20-23 (July) 1956 [Chicago].

Treatment with penicillin V (phenoxymethyl penicillin) was practiced in 110 cases of beta-hemolytic streptococcic infections in children. Unlike solutions of other penicillin salts, the aqueous solution of this preparation is relatively stable in the acid secretion of the gastric juice. It passes through the stomach with little change and shows better absorption from the intestinal tract. All patients were examined by one of the authors, and throat cultures that grew beta-hemolytic streptococci were obtained. If the child was well and the culture negative at the end of six weeks from the start of therapy, he was classified as "cured"; if he became ill up to 60 days after initial therapy, he was classified as a "recurrence"; and if he remained well but the throat culture remained positive or became positive later, he was classified as a "carrier." The drug was dispensed in tablets of 200,000 units (125 mg.). Each patient was given 30 tablets, regardless of age, with instructions to take 3 a day, one on awakening, one at 2 p.m., and one at bedtime.

Four of the 110 patients originally treated were not followed and were excluded from the series. Six of the remaining 106 patients had recurrent attacks, and 17 became carriers at various periods up to 60 days after therapy. Another child developed acute glomerular nephritis on the eighth day. Of the remaining 82 patients, 96% were observed for more than 15 days and 82% for more than 30 days, and all of these were classified as cured. The series contained 56 cases of streptococcic sore throat, 19 pyogenic streptococcic complications (11 cervical adenitis, 4 otitis media, and one each of sinusitis, peritonsilar abscess, vaginitis, and impetigo), and 35 carriers (patients not ill but with positive throat cultures). In all instances in which the patient was clinically ill the response to therapy was that usually expected from penicillin in streptococcic infections; prompt drop in temperature and rapid improvement in the state of well-being. The purpose of the present study is not to discuss the relative value of penicillin V in contrast to other penicillin preparations in the treatment of beta-hemolytic streptococcic infections in children, since the patients as a group are not comparable to those studied previously. With rare exceptions, all the antibiotics and certainly all forms of penicillin are clinically valuable in the treatment of beta-hemolytic streptococcic infections. The authors' results therefore have been judged by rather severe standards. The therapeutic agent must be able to prevent recurrence and to eliminate the streptococcus from the throat for a period more than 21 days, preferably 42 to 60 days. The organism is apparently often held in abeyance but not destroyed by treatment thought to be adequate. A second attack may be a reinfection, but for the present purposes is considered as a recurrence and therefore a therapeutic failure. On the basis of these standards, penicillin V qualifies well as a therapeutic agent against beta-hemolytic streptococcic infections in children. The immediate clinical response was good, and the cultures became negative rapidly. There were no toxic reactions, and the children took the tablets without trouble. Penicillin V given orally appears to be an effective drug for the treatment of streptococcic infections in children.

Staphylococcal Pneumonia in the Newborn: An Epidemic with 8 Fatal Cases. D. W. Beaven and A. F. Burry. Lancet 2:211-215 (Aug. 4) 1956 [London, England].

The authors report on an epidemic of micrococcic (staphylococcic) pneumonia in newborn infants, with eight fatal cases. The nursery involved is the maternity annex of a large private hospital in Christchurch, New Zealand. Overcrowding of nurseries is common throughout the country. Infection of the upper respiratory tract was noticed about the age of 12 to 14 days. On admission, the eight infants in whom the disease was fatal showed striking breathlessness and pallor, which had developed about three days after the onset of the cough. Before death, cyanosis was noted and the temperature fell below normal. Well-marked physical signs were detected in the chest on auscultation. The authors divide the course of the fatal cases into three stages: (1) nasal infection only, with copious mucous purulent nasal discharge, but baby remaining well; (2) infection of the upper respiratory tract, with cough as the main symptom; and (3) pneumonia attended by pallor and breathlessness, often rapidly fatal.

Six of the infants that died underwent radiography of the chest. All six showed evidence of pleural fluid on the right side. Less fulminating cases presented pneumatoceles in an area of consolidated lung; emphysema, diffused or localized; and a spontaneous tension pneumothorax with or without empyema. All six babies had hemorrhagic pneumonia, segmental in distribution and apparently resulting from inhalation. There was a well-marked tendency to suppuration, and the pleural cavity was involved consistently and early. There were no striking lesions in the upper respiratory tract. The nasal fossae contained large amounts of thick mucopus, but the mucosa was usually intact. The middle ear was not involved. There were no gross changes in the larynx or in the trachea to indicate a viral infection. Patients were at first treated with chloramphenicol, but without success. More success was obtained with erythromycin. The dose was initially 20 mg. per pound of body weight daily, given orally in six divided doses, but subsequently, 40 mg. per pound of body weight daily for the first 24 hours was used. Bacteriological studies revealed that many, if not all, of the resistant staphylococci were probably of the same phage pattern (42E/7/73).

DERMATOLOGY

Treatment of Pemphigus with ACTH, Cortisone and Prednisone: Results Obtained in 25 Cases over a Period of Five Years. L. Reznick, W. F. Lever and C. N. Frazier. New England J. Med. 255:305-315 (Aug. 16) 1956 [Boston].

Twenty-five patients with pemphigus were treated at the Massachusetts General Hospital between 1950 and 1954, with either corticotropin (ACTH), cortisone, or prednisone. The patients were followed up to Oct. 1, 1955, or to the time of their death. Fourteen patients had pemphigus vulgaris, 1 had the benign form of pemphigus vegetans (Hallopeau type), and 10 had pemphigus foliaceus. The diagnosis of pemphigus was confirmed in each patient by the demonstration of acantholysis on microscopic examination.

Every patient responded to treatment with various hormone preparations at all times, but very high doses were necessary for the control of some of the exacerbations. An approximately equivalent clinical response was observed with the following daily doses: 20 units of lyophilized ACTH given as a continuous infusion, 40 units of lyophilized ACTH given as an eight-hour infusion, 300 units of lyophilized ACTH intramuscularly, 240 clinical units of ACTH gel intramuscularly, 600 mg. of cortisone orally, and 120 mg. of prednisone (Meticorten) orally. The highest doses administered for the control of exacerbations were 300 units of lyophilized ACTH given intramuscularly, 80 units of lyophilized ACTH given intravenously for 8 hours, 80 units of lyophilized ACTH given intravenously for 24 hours, 300 clinical units of ACTH gel given intramuscularly, 1,500 mg. of cortisone given orally, and 200 mg. of prednisone given orally. Intravenous injections of ACTH were preferred for the control of severe exacerbations, and for maintenance treatment either ACTH gel on alternate days or one of the corticosteroids every day. Of the 14 patients with pemphigus vulgaris, 10 are living; 9 are ambulatory, and 4 of them have been in remission for 49, 43, 25, and 2 months respectively. Four patients died, one of an incidental disease, one of a micrococcic septicemia occurring during a corticotropin withdrawal reaction, and 2 of causes possibly related to the treatment (one of hemorrhages and the other of pulmonary embolism). The one patient with pemphigus vegetans has been in remission for the past 12 months. Eight of the 10 patients with pemphigus foliaceus are living; 7 are ambulatory, and 5 have been in remission for 46, 32, 20, 12, and 3 months respectively. Two patients died, one of an incidental disease, and the other of generalized pemphigus foliaceus while he was not receiving any hormone treatment. Side-reactions to the hormone treatment were common. They included mild mental changes in 11 patients and major psychoses in 2. Bacterial infections occurred in seven patients and resulted in septicemia in two. Vertebral fractures were observed in four patients, all of whom had been given daily large doses of ACTH gel; this method of treatment has since been abandoned. In four patients the withdrawal of corticotropin was followed by a reaction. To prevent withdrawal reactions, ACTH and the corticosteroids should be withdrawn gradually. Evaluation of the clinical response proved to be a better guide to successful treatment than laboratory data. Measurements of the urinary secretion of 17-hydroxysteroids in one patient indicated that a very pronounced hyperadrenocorticoid state must be induced before a severe exacerbation subsides. The same daily dose of ACTH produced a much higher excretion of 17-hydroxysteroids when given as a continuous infusion for 24 hours each day than when given as an intermittent infusion for 8 hours daily.

UROLOGY

Urethrotrigonitis in Women. R. F. Fortuño and B. Rodríguez Lucca. Bol. Asoc. méd. Puerto Rico 48:204-206 (May) 1956 (In Spanish) [Santurce, P. R.].

Urethrotrigonitis is frequent in women. Trichomonas vaginalis is the causal organism in many cases. The symptoms include frequent micturition, dysuria, a burning sensation during urination, urgency to void, feeling of incomplete emptying of the bladder, and hematuria. Symptoms may flare up during or after menstruation. Dyspareunia and pain in the groin, thighs, and iliac fossa may be the predominant or only symptom of this disease. Twenty-five patients were observed in the outpatient department of the San Juan City Hospital. The diagnosis was based on the history and confirmed by cystoscopic examination. None of the patients was suffering from any other disease of the urinary tract. The treatment was as follows: The bladder was emptied and two ounces of a 20% solution of Furacin (nitrofurazone) instilled into it. A suppository of Furacin was placed in the urethra after instillation and held in place for five minutes. The patients were then sent home with instructions to void one hour later. The treatment was given on 10 consecutive days to 15 patients and once a week for two and a half months to 10 patients. Three patients had moderate allergic reactions with aggravation of the symptoms, itching, and edema of the vulva. One had gross hematuria. The reaction was controlled by discontinuing the treatment and giving antihistaminic drugs. The treatment failed in three patients with the acute form of the disease. These patients had a transurethral resection of the neck of the bladder at a later date. Nineteen patients were completely cured upon completion of the treatment. Eight had a recurrence of the disease between three and five months after completion of treatment. The recurrences were permanently controlled by repetition of the treatment. The patients remain cured up to the present, as shown by the follow-up observations.

Treatment of Renal Colic. L. Risholm. Urol. Internat. 2:361-368 (No. 6) 1956 (In English) [Basel, Switzerland].

Posterior splanchnic block was used for routine treatment of severe renal colic in 200 patients admitted to the department of surgery of the University Hospital of Uppsala, Sweden. The anatomic conditions make it simple to block all pain-conducting nerves from the upper urinary tract by conduction anesthesia. All the pain-conducting fibers from the renal pelvis, where the pain probably arises, pass through the celiac plexus and the splanchnic nerves to the spinal cord. The afferent fibers in the vagus nerves do not conduct pain. Posterior splanchnic anesthesia has definite advantages when compared with segmental paravertebral anesthesia; in particular, it is easier to carry out, and that is why it is recommended. The needle is introduced immediately below the 12th rib, about 7 cm. from the midline, and is directed 30 to 40 degrees medially and 10 to 20 degrees cranially. At a depth of from 7 to 8 cm., the point of the needle meets a bony resistance, the dorsolateral aspect of the vertebral body. The needle is then withdrawn a little and is redirected

PATHOLOGY

Needle Biopsy of the Liver in Cirrhosis: Diagnostic Efficiency as Determined by Postmortem Sampling. H. Braunstein. A. M. A. Arch. Path. 62:87-95 (Aug.) 1956 [Chicago].

While liver biopsy by the transcutaneous needle method has become a widely accepted diagnostic procedure in the diagnosis of conditions diffusely affecting the liver, such as hepatitis, fatty liver, and amyloidosis, its efficiency in the demonstration of focal lesions and those with less uniform characteristics has been questioned. Investigation by a sampling technique at the time of postmortem examination would aid in evaluating the accuracy of diagnosis of various types of portal cirrhosis by needle biopsy. Accordingly, the livers of 30 patients with various forms of portal cirrhosis were obtained at autopsy and 18 needle specimens taken from different portions of each liver with the Vim-Silverman needle. The technique used has been described by Billing and associates. It consisted of procuring 12 specimens from different but standardized areas in the right lobe and 6 from the left lobe. Each adequate needle sample was classified as to the type of cirrhosis and severity of the lesion, on the basis of sections prepared in standard fashion and stained with hematoxylin and eosin and, where necessary for determination of degree of fibrosis, the Masson trichrome stain.

Definite diagnosis and ultimate classification rested upon gross examination of the lesion at the time of autopsy and microscopic study of the postmortem sections, which usually consisted of two or three blocks measuring 1.5 cm. in diameter. A total of 507 adequate needle samples were obtained, namely, 224 in 13 cases (autopsies) of nutritional cirrhosis, 131 in 8 cases of postnecrotic cirrhosis, and 152 in 9 cases of posthepatitic cirrhosis. Of the 507 adequate samples, only 10 failed to reveal cirrhosis. In cases of nutritional cirrhosis the accuracy of diagnosis was 100%. The degree of the fibrosis revealed a remarkable uniformity in all areas of the liver. In cases of post- atitic and postnecrotic cirrhosis the accuracy of recognition presence of cirrhosis was roughly 96%, but in many of ·ly negative samples some fibrosis was present. In the forms of cirrhosis, there was considerable variation in ne intensity of fibrosis, and the biopsy method would therefore be of little value in the appraisal of severity. It is concluded that needle liver biopsy represents a singularly accurate method of diagnosing cirrhosis of all three types. A liver biopsy that fails to demonstrate cirrhosis or fibrosis rules out cirrhosis with reasonable certainty. As a means of estimating the severity of the process, accuracy may be assumed only in the case of nutritional cirrhosis.

Massive Hematemesis Without Gross Lesion. J. F. Kuzma. Am. J. Gastroenterol. 26:150-152 (Aug.) 1956 [New York].

Massive upper gastrointestinal hemorrhage is a cause of great concern to the pathologist who has to explain the mechanism of hemorrhage or demonstrate its anatomic cause. Many hospital reports refer to hemorrhage of undetermined origin, but massive bleeding from the stomach should be traceable to an anatomic lesion. Material obtained from patients with upper gastrointestinal hemorrhage but otherwise in good health whose stomachs were available for study either as surgical or as autopsy specimens has been reviewed in an attempt to find an anatomic explanation for the hemorrhage. Superficial erosions were discovered in most of the stomachs. The reason for failure to identify these erosions grossly lies in the fact that many of them are covered or filled with fibrin and pseudomembrane. Moreover, these microscopic erosions commonly begin in the furrows of the gastric mucosa and are not readily seen. The pseudoepithelial layer of the stomach may play an important part in developing a surface membrane, which fills the zones of erosion. There is a strong suggestion that many of these erosions are located in the area of the lesser curvature. They occur primarily in stomachs otherwise designated as those of hypertrophic gastritis. Only one case was found in an atrophic mucous membrane. The cause of these microscopic and near-microscopic erosions has not been determined.

The Behavior of Carcinoid Tumors of the Intestinal Tract. D. M. Spain. Am. J. Gastroenterol. 26:162-169 (Aug.) 1956 [New York].

Benign carcinoid tumors may produce a variety of manifestations as a result of local involvement of the intestinal tract, e. g., obstruction, intussusception, diarrhea, hemorrhage, pain, and weight loss. Carcinoid tumors are frequently malignant, but long survival in the presence of metastases is not uncommon. The syndrome associated with malignant carcinoid tumor consists of predominantly right-sided valvular endocardial fibrosis, a peculiar type of skin telangiectasia, skin cyanosis and blushing secondary to vasomotor changes, and asthma-like symptoms due to bronchoconstriction. The substance responsible for this syndrome is believed to be 5-hydroxytryptamine, regarded as a specific hormone of the enterochromaffin cell system that is also elaborated in great quantities by carcinoid tumors.

Changes in the Intramural Coronary Branches in Coronary Arteriosclerosis. O. Saphir, L. Ohringer and R. Wong. A. M. A. Arch. Path. 62:159-172 (Aug.) 1956 [Chicago].

Factors that have been regarded as important in arteriosclerosis and atherosclerosis include heredity, hypertension and obesity, and those related to endocrine disturbances, such as steroid hormone relationships, sex, thyroid dysfunctions, diabetes, and gout. In the past, inflammatory factors were considered as possible causes, but now the weight of evidence seems to favor an abnormal cholesterol metabolism as of prime importance. The old concept of inflammation as at least one factor in the causation of coronary arteriosclerosis is discussed. The studies described were designed to determine whether what appears as primary coronary artery sclerosis may not, in certain instances, actually represent the end-stages of an inflammatory process. Since it was felt that the main coronary arteries might no longer show the pathogenesis of these lesions, the intramural branches of the coronary arteries were examined. Although it had been planned to study the myocardium in instances of coronary arteriosclerosis in patients up to the age of 40, it was thought more profitable to include also patients up to 50 years of age, especially as the increase in the incidence of arteriosclerosis that the authors have observed during the last 15 years involves particularly the age group from 40 to 50 years.

The myocardiums of 100 patients were examined with the aid of the microscope. Only those cases were selected for study in which the final autopsy diagnosis was coronary arteriosclerosis or coronary atherosclerosis, with or without myocardial changes. There were 32 females and 68 males. Remnants of inflammatory changes were found in the intramural branches of the coronary arteries in 82. These changes consisted of perivascular cellular infiltrations, perivascular or adventitial fibrosis, intimal fibrosis and hyalinization, the arteritis obliterans type of lesions, and fibrous changes in the media. In a number of instances, these changes were characteristic of old periarteritis or panarteritis. Autopsy findings and a review of the clinical histories disclosed evidence of endocarditis in 12 cases, in 8 of which it was most probably rheumatic in origin. Ten patients volunteered histories suggesting hypersensitivity or showed autopsy findings interpreted as allergic in origin. Six other patients showed changes in the intramural branches of the coronary arteries that were indistinguishable from those seen in the group with hypersensitivity. The relation of the changes in the smaller branches of the coronary arteries to those in the large branches is discussed, and it is suggested that the intramural coronary artery disease may provide a clue to the nature of the changes in the large coronary arteries that are indistinguishable from primary arteriosclerosis and atherosclerosis. The question is raised whether perhaps the increase in coronary arteriosclerosis in the younger age group may not be associated with hypersensitivity related to the common use of antibiotics and chemotherapeutics.

BOOK REVIEWS

Psychoanalysis and Psychotherapy: Developments in Theory, Technique, and Training. By Franz Alexander, M.D., Director, Chicago Institute for Psychoanalysis, Chicago. Cloth. $4.75. Pp. 299. W. W. Norton & Company, Inc., 55 Fifth Ave., New York 3, 1956.

In this book the author comprehensively presents the developments of the past 20 years in the theory and technique of psychoanalysis. His purpose is to clarify prevailing views and practices and to call attention to the discrepancies existing between our theoretical model of procedure and what actually takes place in treatment. Of special interest are his views in regard to the application of psychoanalytic theory to those forms of psychotherapy that differ from traditional analysis. The author first discusses the impact that he believes psychoanalysis has made on Western culture. He then traces, in a remarkably concise manner, the development of psychoanalytic theory from its inception to the present. He reviews those aspects of theory that have enjoyed general acceptance and then traces early modifications of theory as they oscillated between an overemphasis on one of two basic therapeutic factors: psychoanalysis as primarily a cognitive process (ego-analysis) and psychoanalysis as primarily a meaningful emotional experience. In discussing more recent developments, he clarifies his view of the transference relationship as a corrective emotional experience and the axis around which present analytic technique revolves. For those versed in psychoanalysis the only ideas that may appear to be new or unfamiliar are those the author proposes in his discussion of the countertransference phenomenon and the relationship of classic analysis to other forms of psychotherapy.

With regard to countertransference, the author proposes that the analyst should attempt to replace his spontaneous countertransference reactions with attitudes that are consciously adopted to create the type of emotional climate the patient's dynamic situation demands. In discussing more recent forms of psychotherapy, he states that they differ from the classic technique in quantity but not in their basic characteristics. He points out the value of the shorter forms of supportive and uncovering psychotherapy for patients not amenable to the classic technique. He deals extensively with the therapeutic implications of regression and with the technical problems regarding the frequency of interviews and planned interruptions of treatment. One chapter is devoted to the controversial issues that arose in response to "Psychoanalytic Therapy," written by the author of the present book and Thomas French in 1946. The last quarter of the book is devoted to the problem of psychiatric training in psychoanalytic institutes and medical schools. In general, it is gratifying to note the author's emphasis on empirical data as the source of modification in analytic theory rather than on a priori assumptions found in some psychoanalytic work. It is interesting, however, that in his praise for psychoanalysis the author seems to ascribe to it almost all that has been learned of the psychology of man. He refers to philosophy only when it agrees with analytic theory; he gives only a passing nod to sociology and anthropology and does not mention the vast field of academic psychology at all. One cannot help wondering at this omission.

Pathologische Anatomie der raumbeengenden intrakraniellen Prozesse. Bearbeitet von K. J. Zülch und E. Christensen. Band III, Handbuch der Neurochirurgie. Herausgegeben von H. Olivecrona und W. Tönnis. Cloth. 298 marks. Pp. 800, with 473 illustrations. Springer-Verlag, Reichpietschufer 20, (1) Berlin W. 35 (West-Berlin); Neuenheimer Landstrasse 24, Heidelberg; Göttingen, Germany, 1956.

This outstanding book is divided into two sections. The first, Biology and Pathology of Brain Tumors, is by Zülch and occupies the greater part of the volume. The second deals with the pathology of intracranial hemorrhage; it is only 30 pages long and is by Christensen. The first section is representative of German medical writing at its best. It is typical of the scientific work that was expected of German authors over 25 years ago but of which we have seen so little in more recent years. This volume is a classic and will undoubtedly be the standard reference work on this subject for many years to come. The literature on the subject from the entire world has been carefully and intelligently reviewed. The work and opinions of all investigators worthy of consideration have been presented. The author has stated his own opinion and his reasons for differing with the views of others. The bibliography is unusually complete; the author and the publisher are to be congratulated on having adopted the alphabetical and columnar style of arranging the names of authors cited in the bibliography. This makes for much easier reference than the usual German style. It is still difficult, however, to distinguish the different works of two different authors with the same last name. Each type of tumor is taken up separately. The author has followed the classification of Percival Bailey of Chicago quite closely. He has recognized, as many neuropathologists have, that there is a definite difference in behavior between the astrocytomas of the cerebral hemispheres and those of the cerebellum. He has endeavored to distinguish between these two types of tumors by grouping the cerebellar ones with the polar spongioblastomas, which commonly involve the neural axis and the optic nerves and chiasm. This does not seem to be a proper or satisfactory solution to the problem. On the other hand, the grouping of the various tumors of peripheral nerves, referred to by others by such terms as perineural fibroblastoma, neurofibroma, and schwannoma, seems entirely justified.

Each type of tumor is taken up similarly. The author first discusses the historical aspects and its place in the classification; the frequency, sex and age incidence, and common site of origin are then presented. He next takes up the gross and microscopic appearance of the tumor. These aspects are well and profusely illustrated. The tendencies, if any, toward degenerative changes, recurrence, and metastasis are then considered. Lastly, the author briefly discusses the pathological differential diagnosis, the prognosis, and therapeutic possibilities. In addition to the various tumors of the glioma group, the neurinomas, meningiomas, angioblastomas, pituitary tumors, blood vessel tumors and malformations, and metastatic tumors, he discusses parasitic and granulomatous involvement of the brain and arachnoiditis. He concludes with a brief presentation of a few points concerning technical methods for preserving, sectioning, and staining these tumors. The second section is not comparable to the encyclopedic study of tumors that is presented in the first. It consists of a brief discussion of epidural, subdural, subarachnoid, and intracerebral hemorrhage. The publisher is to be congratulated on the splendid manner in which this book is presented. The printing is excellent, and the illustrations are well reproduced. Everyone having to do with tumors of the brain should have this volume readily available, although the high price may make that impossible.

The Practice of Psychiatry in General Hospitals. By A. E. Bennett, M.D., Associate Clinical Professor of Psychiatry, University of California, School of Medicine, San Francisco, Eugene A. Hargrove, M.D., Assistant Professor of Psychiatry, University of North Carolina, School of Medicine, Chapel Hill, and Bernice Engle, M.A., Research Associate, Department of Psychiatry, University of California, School of Medicine, with contributing authors. Cloth. $4. Pp. 178. University of California Press, Berkeley 4, 1956.

In addition to developing psychiatric departments in several general hospitals, Dr. Bennett and co-workers conducted a survey that disclosed that less than 1% of patients suffering from mental illness were accommodated in American and Canadian hospitals. They incorporated their findings into a scientific exhibit that attracted much attention and stimulated many inquiries. They have prepared this book from the material collected for the exhibit; here they consider the main problem connected with installing and operating a psychiatric department within a general hospital. They believe that "as the advantages of the psychiatric unit are better understood patients will generally be admitted to general hospitals for treatment of acute mental illness to the same extent as for other acute medical illnesses, disorders and accidents; that modern medicine will eventually accept its responsibility to treat the entire person."

These book reviews have been prepared by competent authorities but do not represent the opinions of any medical or other organization unless specifically so stated.

The foreword, introduction, and preface of this volume are followed by 10 chapters and a general index. At the end of each chapter there are lists of references. Although the authors are dedicated to the integration of psychiatry into the practice of medicine in general hospitals, their organization of this book does not describe the process. The reader will gain practical information on the staffing of a psychiatric unit, training programs, administration, architecture, psychiatric referral, medicolegal aspects, health insurance, the day hospital, and special treatments. Sections on these separate subjects are contributed by several authors, some of whom have special competence in the problems pertaining to the hospital practice of psychiatry. These separate chapters are well written and apparently are intended as sources of reference when the establishment of a psychiatric unit in general hospitals is under consideration. The value of the book would be greatly enhanced by the addition of a chapter describing the functioning of the departments of psychiatry in one or more hospitals. It is also hoped that in a subsequent edition the authors will describe in detail the various improvements in medical care they have observed in general hospitals in which psychiatric units have been functioning for some time. Such observations would be of practical interest to general practitioners and medical specialists.

Human Perspiration. By Yas Kuno, M.D. Publication 285, American Lecture Series, monograph in Bannerstone Division of American Lectures in Physiology. Edited by Robert F. Pitts, M.D., Ph.D., Professor of Physiology and Biophysics, Cornell University Medical College, New York. Cloth. $9.50. Pp. 416, with 76 illustrations. Charles C Thomas, Publisher, 301-327 E. Lawrence Ave., Springfield, Ill., Blackwell Scientific Publications, Ltd., 24-25 Broad St., Oxford, England, Ryerson Press, 299 Queen St., W., Toronto, 2B, Canada, 1956.

This study of the present knowledge of perspiration is based primarily on the personal observations of the author. Although derived from a similar volume written in 1934 by the same author, the book has been radically changed in both style and context. The writer believes that sweating deserves far more consideration, from both physiological and social aspects, than has usually been accorded to it; and his reasons are advanced in a lucid and convincing manner. The individual chapters include detailed descriptions of the development, anatomy, chemistry, and physiological mechanisms of the human sweat apparatus. Additional chapters describe regional and general forms of sweating, as well as their diverse relationships to the chemistry of the blood, and the influence of drugs, temperature, and stress. Of particular interest are the author's concepts of the skin chloride shift in sweating and the reabsorption of sweat in the sweat duct. The author presents a method for the suppression of local hyperhidrosis; this method, consisting of the administration of a 10% solution of formaldehyde by iontophoresis, has its drawbacks. The discussion of the significance of water debt during physical exercise in hot weather is of great interest. The book is well written and printed, and the illustrations and tables are both adequate and clearly reproduced. Although the volume is small, it is filled with valuable information.

Clinical Selections in Dermatology and Mycology. By Frederick Rehm Schmidt, A.B., M.D., Associate Professor of Dermatology, Northwestern University Medical School, Chicago. With contributions by 36 specialists from various lands. Cloth. $10.50. Pp. 505. Charles C Thomas, Publisher, 301-327 E. Lawrence Ave., Springfield, Ill.; Blackwell Scientific Publications, Ltd., 24-25 Broad St., Oxford, England, Ryerson Press, 299 Queen St., W., Toronto 2B, Canada, 1956.

Since each contribution to this volume is written by an expert on a specific disease, this is not a textbook for the student but rather a summary of the knowledge and experience of an authority on a subject, condensed and maturely presented both for the practicing physician interested in a special topic and for the dermatologist. No attempt is made to present the material in an integrated or coordinated form. This is not a disadvantage, however, inasmuch as the contributions cover the important subjects in a thorough and thoughtful manner and properly emphasize controversial opinions and original ideas. Some of the more important contributions include the chapters on nutritional dermatoses, the collagen diseases, and the pigmentary dermatoses. Original methods of treatment are emphasized, and the use of simple, practical remedies is advised whenever possible. A large portion of the book deals with the pathogenesis, diagnosis, and therapy of fungous diseases, including those prevalent in tropical regions. The psychosomatic dermatoses are not neglected; and the role of enzymes, vitamins, and diet in the cutaneous economy is also described. For the most part, the discussions are written with simplicity and clarity of style, and the bibliography is adequate. This reference book should be welcomed by those interested in both the simple and the complex aspects of dermatology and mycology.

Allgemeine Theorie der menschlichen Haltung und Bewegung als Verbindung und Gegenüberstellung von physiologischer und psychologischer Betrachtungsweise. Von Dr. F. J. J. Buytendijk, o. Professor der Psychologie der Reichsuniversität Utrecht, Utrecht, Holland. Titel der Originalausgabe: Algemene Theorie der menselijke Houding en Beweging, 1948. Cloth. 39.60 marks. Pp. 367, Springer-Verlag, Reichpietschufer 20, (1) Berlin W35 (West-Berlin); Neuenheimer Landstrasse 24, Heidelberg; Gottingen, Germany, 1956.

This book, competently translated from the Dutch, reflects the author's thorough knowledge of physiology, psychology, and philosophy. He endeavors to give the theoretical foundation of the movements and postures as purposeful acts; and, though he emphasizes the merits of the Gestalt theory, he shows that the traditional physiological and psychological investigations do not provide an adequate explanation. In addition to an analysis of various types of voluntary and reflex movements, the author discusses, in a fascinating chapter, the facial expressions. A section on the genesis of human movements, which stresses also the learning processes, and one on the sex and age differences of movements conclude this informative and challenging book. The author's phenomenological analysis of the movements and his discussion of the relevant physiological, psychological, and clinical literature should make fascinating reading for physiologists and neurologists. His holistic approach to the problem of human behavior is related to that of the Heidelberg neurological school (vs. Weizsäcker). The printing and binding are excellent.

The Office Assistant in Medical or Dental Practice. By Portia M. Frederick, Instructor, Medical Office Assisting, Long Beach City College, Long Beach, Calif., and Carol Towner, Executive Assistant, Department of Public Relations, American Medical Association, Chicago. Cloth. $4.75. Pp. 351, with 55 illustrations. W. B. Saunders Company, 218 W. Washington Sq., Philadelphia 5; 7 Grape St., Shaftesbury Ave., London, W.C.2, England, 1956.

This book is a manual of instruction for medical and dental office assistants. All the functions of an office assistant are covered, from those that make the occupation a career to bookkeeping and banking. Specific instructions and modes of conduct in meeting patients and handling telephone calls are stressed. The importance of a good "office girl" to a physician or dentist is also stressed. Record-keeping, handling of mail, and office appointment systems are well discussed. There are chapters on the techniques of sterilization, injection, the care of instruments, and administrative duties. Emphasis is placed on the importance of all possible aids to the practitioner in saving time and pleasing the patients. There is much information about medical societies and their organization that should be of help to an office assistant. The authors are well qualified to present this material, and they have done so in easily readable fashion. The book is well illustrated and can be highly recommended to office assistants.

Proctology. By Harry E. Bacon, B.S., M.D., Sc.D., Professor and Head Department Proctology, Temple University Medical School, Philadelphia, Stuart T. Ross, A.B., M.D., F.A.C.S., Attending Proctologist, Nassau Hospital, Mineola, New York, and Porfirio Mayo Recio, B.S., M.D., M.Sc., Assistant Professor Surgery, College of Medicine, University of Philippines, Manila. Portions of this book were published previously under title "Essentials of Proctology," by Harry E. Bacon, 1943. Cloth. $10. Pp. 441, with 233 illustrations. J. B. Lippincott Company, 227-231 S. Sixth St., Philadelphia 5; 2083 Guy St., Montreal, Canada, Pitman Medical Publishing Co., Ltd., 39-41 Parker St., Kingsway, London, W.C.2, England, 1956.

This excellent volume is designed for the medical student, general practitioner, and general surgeon, but it is also a valuable addition to the library of the proctologist. Illustrations are clear-cut and informative. Especially helpful to the medical student are the tables of differential diagnosis taken from earlier works of the senior author. The authors have given some attention to the etiological importance of anal infection in the common anorectal disorders, such as fissure, hemorrhoid, abscess, and fistula. The inclusion of an excellent chapter on intestinal parasites is timely and appropriate.

QUERIES AND MINOR NOTES

TUBERCULOSIS CASE-FINDING IN TEACHERS

To the Editor:—*The teachers in the school district in which I am the doctor are compelled to have an x-ray of the chest every year. The superintendent wants me to find out if there is any danger in having annual chest x-rays. Would there be any difference whether the standard or the miniature x-ray equipment were used? Is there any possibility of these annual x-rays stimulating the growth of latent cancer cells? Would the factor of an individual being under x-ray therapy, or having had or planning to have diagnostic x-ray studies, be of any great consideration? Would you advise any other means for the detection of tuberculosis in this type of adult population?*

John F. Smith, M.D., Monterey Park, Calif.

This inquiry was referred to two consultants, whose respective replies follow.—Ed.

Answer.—There is no available evidence to indicate that the x-ray exposure for an annual film of the chest is in any way harmful. The recent writings on this subject have pertained to those who are exposed to x-rays a great deal in their work and those who receive x-ray treatment for various conditions. There would be no difference whether standard or miniature x-ray film equipment were used, as the amount of exposure is extremely small in both procedures. No evidence is available to suggest the possibility that the making of annual x-ray films stimulates the growth of cancer cells. It is not unusual to make periodic x-ray film inspections of the chests, seeking evidence of pulmonary metastases of persons who are under x-ray therapy for malignancy elsewhere in the body. Among teachers, or any other group, the best procedure for the detection of tuberculosis is giving all members the tuberculin test to identify those who are harboring tubercle bacilli. The reactors have x-ray film inspection of the chest periodically to detect gross lesions that may evolve while the disease is still in the silent stage. It is only present tuberculin reactors and those who subsequently become reactors who develop clinical tuberculosis. Therefore, there is no reason to make periodic x-ray film inspections of the chest for tuberculosis of those who are uninfected and who do not react to tuberculin.

This procedure is widely used and recommended by the Committee on Tuberculosis of the American School Health Association, in cooperation with tuberculosis and health associations in several states, where schools are officially certified on the basis of tuberculosis control work in progress. The details of this program may be obtained from Dr. A. O. DeWeese, Executive Secretary, American School Health Association, Kent University, Kent, Ohio.

Answer.—The amount of total body radiation received during a single chest x-ray is only a small fraction of the limit considered tolerable by the National and International Commissions. There are not sufficient data on the difference in exposure between standard and miniature x-ray equipment. There is no evidence to make it seem likely that doses of radiation in this range will be carcinogenic. At the present time a chest x-ray is the best method for detecting early pulmonary tuberculosis in individuals with a positive tuberculin reaction.

DIATHERMY APPARATUS

To the Editor:—*Are there any harmful rays emitted by a diathermy machine the specifications of which are 110 volts, 60 cycles per second, 7 amperes? The operator stands next to the machine, or within half a foot of it.*

M.D., Pennsylvania.

Answer.—*It is assumed that the inquirer is asking about* either a short wave or microwave diathermy apparatus. Diathermy apparatus is intended to provide energy transmitted by electromagnetic waves to the patient for the purpose of heating body tissues. In properly constructed diathermy units, the emission of such energy through the cabinet is so negligible that for all practical purposes there is not even the mildest heating effect on the operator or other persons contacting or standing in close proximity to the cabinet of the apparatus.

MULTIPLE SCLEROSIS VACCINE

To the Editor:—News Facts, *a publication of Toronto, Canada, states that a Dr. Antonina Shubladze at the Soviet Institute of Virology has perfected a vaccine for curing multiple sclerosis and that it is manufactured and distributed by the Kharkov Serum and Vaccine Institute in Moscow. A patient wishes to either confirm or refute the existence of such a vaccine, and, if such a vaccine exists, he would like to have the address of a distributor in the United States so that it could be made available to him.*

M. D., Nebraska.

Answer.—This inquiry undoubtedly refers to a preparation manufactured and distributed from the Metchnikoff Institute in Kharkov, where it is called the "Vaccine of Margoulis and Choubadze." Its nature has been carefully studied in the United States, but whether it fulfills the criteria of a vaccine for multiple sclerosis is extremely dubious, and there is no evidence at all to suggest that it can cure cases of that disease. It is not, as far as is known, distributed in the United States. The proponents of the preparation, in the instructions that accompany it, recommend its use in early cases of multiple sclerosis and in encephalitis. There are, of course, at least two separate diseases and encephalitis may be caused by a host of recognized and unrecognized organisms and conditions.

To limit this discussion to multiple sclerosis, the printed instructions also state that "some early cases may be helped." In the judgment of this consultant, that statement says nothing, since spontaneous remission characterizes early cases of multiple sclerosis. Brickner (*Bull. Neurol. Inst. New York* 4: 665, 1936) and Putnam (*J.A.M.A.* 112: 2488, 1939) studied over 100 reports of treatments for multiple sclerosis and showed that the reported improvement corresponded almost exactly (48%) with the frequency with which early cases go into spontaneous remission.

The preparation of Margoulis and Choubadze was studied at the department of zoology, Rutgers University, which reported (De Falco: Personal communication, 1956) that the material gave a weak protein test and was a homogenate, probably of brain. The supernatant portion faintly reacts to antiserums for rat and mouse but does not react to pig, dog, sheep, chicken, horse, human, rabbit, or hamster antiserums. It is probable that the material is of rodent origin, not necessarily rat, as demonstrated by the naphylactic death of all of seven guinea pigs two to five minutes after they were given rat serum intravenously four weeks after sensitization with two doses of the "vaccine" of 0.25 cc. given on alternate days. The available data do not justify the use of this material, except for investigational purposes by the qualified persons. This is emphasized by Tore Broman (Personal communication, 1956), professor at Göteborg, under whose direction Sigvard Flodmark and Arne Linde have been conducting clinical studies of the Margoulis and Choubadze preparation. There is evidence that patients treated with it develop antibodies against mouse serum, and Broman believes there is at least a theoretical possibility of inducing an encephalomyelitis. His comment, with which this consultant is in complete agreement, is that the chances for benefit are small compared with the possibility of doing serious harm.

The answers here published have been prepared by competent authorities. They do not, however, represent the opinions of any medical or other organization unless specifically so stated in the reply. Anonymous communications and queries on postal cards cannot be answered. Every letter must contain the writer's name and address, but these will be omitted on request.

TRANSFUSIONS AND THE HEMOGLOBIN CONTENT

To the Editor:—*The following statement appeared in an abstract of a lecture by Dr. Howard R. Bierman, April 12, 1955: "More transfusions are required to raise the Hgb content from 11 to 14 Gms. than to raise it from 2 to 11 Gms." I could not find an explanation in the literature available to me.*

Hamza I. Munib, M.D., Amarillo, Texas.

Answer.—In context, the statement emphasizes the practical point of maintaining a physiologically sufficient, although reduced, hemoglobin level in patients with anemia due to neoplastic diseases, because of the greater expenditure of effort and blood to return the hemoglobin to the normal 100% level. Little, if any, added value has been demonstrated by transfusing to normal or even polycythemic levels over that of maintaining a comfortable and sufficient hemoglobin level. In some patients with severe anemia due to the leukemias, it has often been observed that one or two units of blood will initially cause far greater rises in hemoglobin levels than an equivalent amount of the blood when the hemoglobin level is already elevated. Many mechanisms are probably involved, a few of which can be mentioned. The total blood volume space is contracted in proportion to the severity of the anemia (McMichael and others: *Lancet* 1:637, 1943). Thus the initial replacement of blood would appear to correct the anemia more efficiently than subsequent transfusions with an expanding blood volume space.

Many patients with neoplastic diseases, particularly the leukemias, often maintain a depressed hemoglobin level for prolonged periods. Apparently the increased rate of erythrocyte destruction is kept in partial compensation by an increased erythropoietic activity, the equilibrium of which determines the hemoglobin level that will be maintained (Crosby and Akeroyd: *Am. J. Med.* 13:273, 1952; Finch and Coleman: *J. Clin. Invest.* 32:567, 1953). It is known that erythropoiesis is most active at the lowest hemoglobin levels and would therefore be of greater assistance at the lower rather than the higher levels if the hemolytic component is brought under control (Dacie: The Haemolytic Anaemias: Congenital and Acquired, Grune & Stratton, Inc. 1955, p. 15). This is further supported by greater reticulocytosis and the presence of normoblasts at the lower levels. On the other hand, transfusions at elevated hemoglobin levels tend to depress erythropoiesis (Boycott and Oakley: *J. Path & Bact.* 36:205, 1933).

ATTACKS OF GASPING FOR AIR

To the Editor:—*For five years, periodically, a college graduate, aged 31, has awakened at night from sound sleep gasping for air. These episodes occasionally occur during the day if he happens to be napping. After his first college year he enlisted in the Marines and was sent to the Pacific theater, where he participated in combat during the entire campaign and was in the first wave that landed on Okinawa. His first symptoms happened on that island. From Okinawa he flew to Guam, where he had another attack. On returning to the United States, he went back to college, graduating in 1952 with a major in physical education and English. At the present time he is a coach in a high school. Last summer an electrocardiogram was made. The cardiologist reported that everything was within the normal level and that he could run a mile if he wanted to. A roentgenogram was normal. He is married and the father of six children. His married life seems to be happy. He has been seen by two colleagues, and the only conclusion we reached was that he is suffering from hyperventilation syndrome. We have been unsuccessful in reducing the frequency and severity of the attacks. Please advise how to cope with this case.* M.D., Wisconsin.

Answer.—There are two possibilities that must be considered in explaining these symptoms: (1) cardiac disease and (2) a hyperventilation syndrome. Cardiac disease would seem to have been pretty well excluded by the fact that the patient has no abnormal heart sounds, the fact that x-ray examination shows no enlargement of the heart, and the fact that the electrocardiographic tracings are within normal limits. In addition, the patient is only 31 years of age. The clinical history certainly would suggest that the patient's difficulty is due to a hyperventilation syndrome. There are many factors that would account for such a condition. First of all, the original attack occurred while the patient was in Okinawa, where he was undoubtedly under emotional strain. It is also interesting to note that his occupation is of such a type that he is subject to great emotional stress from time to time. It would be advisable to have the patient try breathing into a paper bag, to see if this will control his attacks. If this does not prove successful, it might be advisable for the patient to consult a psychiatrist to aid in dealing with his problem.

"TRUTH SERUM"

To the Editor:—*Please give an explanation of the term "truth serum" as it appears in the lay press.*

William K. Owens, M.D., Pulaski, Tenn.

This inquiry was referred to two consultants, whose respective replies follow.—Ed.

Answer.—So-called truth serum is not a serum, but, as stated by McCartney in his book, "Understanding Human Behavior" (New York, Vantage Press, Inc., 1956), "it is the injection of a drug so that the patient can recall a repressed memory." This technique, called narcosynthesis, came into general use during World War II. A solution of thiopental (Pentothal) sodium or amobarbital (Amytal) sodium is slowly injected intravenously until conscious control is lost, and then the subject is questioned about past experiences. Without conscious censorship the person is apt to tell the "truth."

Answer.—Truth serum usually means a form of barbiturates for intravenous administration given slowly, so that the individual will respond to questioning but his inhibitions will be dulled or removed. An interesting chapter entitled Narcoanalysis for Criminal Interrogation, pages 945 to 979, can be found in "Legal Medicine," edited by Gradwohl (St. Louis, C. V. Mosby Company, 1954).

ENTERITIS IN URANIUM CAMPS

To the Editor:—*In regard to the query and minor note "Enteritis in Uranium Camps," in* The Journal, *June 30, 1956, page 931, the reason might well be arsenic in the water. Arsenic is often found in the regions of mines of this nature and, when taken in small quantities, causes severe enteritis with weight loss. It would be advisable to have chemical analyses of the water used in cooking, for arsenic as well as for other minerals.*

Leland Fuller, M.D.
900 S. Central Ave.
Lodi, Calif.

The above letter was submitted to the consultant who answered the query referred to, and his comments follow.—Ed.

To the Editor:—*Although enteritis tends to be associated with arsenic more as an acute manifestation than on chronic exposure—and the reported condition appears to fall in the latter category—it would seem well to inquire into the possibilities of arsenic absorption in these mines, through analysis not only of the water but also of the urine. However, the probability of arsenic being the cause is low, as reports of such cases are rare, even where arsenic is associated with minerals being mined, and as other symptoms pointing to arsenic as the cause would be expected.*

SURGICAL SPONGES AND HEPATITIS

To the Editor:—*At our hospital the surgical sponges are prepared manually from bulk gauze. After use in surgery they are thoroughly washed, dried, refolded, and autoclaved for repeat use. Is this a safe method of handling surgical sponges? My immediate concern is the possible transmission of homologous serum hepatitis.* *C. R. Heinzerling, M.D., Chaska, Minn.*

Answer.—Although the etiological agent in serum hepatitis is believed to be a virus, it has not been isolated. All known viruses are destroyed by proper autoclaving cycles (121 C or 250 F for 20 to 30 minutes). There is no reason to suspect that sponges, prepared for repeat use as described above and properly autoclaved, would transmit the infectious agent.

Federal-State Rehabilitation Teamwork Stressed • •
Russian Medical Publications to Be Translated • •

STUDIES OF U. S. EMPLOYEE HEALTH INSURANCE

Various federal agencies are now making cost estimates for carrying out a payroll deduction plan of basic health insurance for federal workers. The data are being gathered by the General Accounting Office (GAD) for the House Civil Service Committee, which is doing a study on the advisability of legislation in this field for the 85th Congress convening Jan. 3. In the last session of Congress, the administration's proposal for a program of catastrophic insurance for all federal employees, with the government paying all the premium, came up against strong opposition from the nonprofit plans and some labor spokesmen. They argued that basic coverage should come first. Accordingly, the administration bill failed to pass. Then, committee chairman Tom Murray directed the accounting office to make a study of the feasibility and probable cost of a basic plan with payroll deductions.

Early in September, 11 commercial and nonprofit plans were asked to submit informations on what would be required of federal agencies in administering a basic health program. The GAO then drafted criteria based on this data and submitted them to the agencies. Chairman Murray has set Dec. 31 as the deadline for a committee report on a basic program. Before submitting its plan for catastrophic coverage to the last Congress, the administration had sought an agreement among various insurers on basic coverage for federal workers without payroll deductions, but it was abandoned when no agreement could be reached.

CENTER FOR RESEARCH ON AGING

To encourage and finance research in the mechanisms involved in aging, the Public Health Service has established a Center for Research on Aging, under the direction of the National Institutes of Health. Dr. G. Halsey Hunt, presently associated chief of the PHS Bureau of Medical Services, will head the new center as of Nov. 19. Coordinating all activities in this field in the office of Surgeon General Burney will be Dr. John W. Porterfield, recently named as assistant to Dr. Burney.

The PHS objective is to assist universities and other research institutions in setting up broad research programs. One of the initial steps will be to encourage nonfederal organizations to establish comprehensive research centers on aging, which will be aided financially by the National Institutes of Health. For several years a Federal Council on Aging has attempted to coordinate research in this field.

In describing the new center, Secretary Folsom said: "I am hopeful that this new effort will help bring answers to some of the most critical and challenging health problems of our times. There are more than 12,000,000 people in this country today who are over the age of 65; by 1970, there will be more than 18,000,000. Many of our older citizens have special health problems. It is important that more be done to help these problems—to help older persons to greater independence and self-sufficiency and a life more free of disease and disability."

REHABILITATION PROBLEMS

The federal-state partnership in solving medical and rehabilitation problems was emphasized repeatedly during the four-day annual meeting in Washington of the National Society for Crippled Children and Adults. This theme was underscored during a panel discussion of officials of the Department of Health, Education, and Welfare and the Public Health Service. Presiding over this panel was Dr. Elmer Hess, immediate past-president of the American Medical Association. Dr. Leroy E. Burney, PHS surgeon general, warned against the "isolated or exclusive approach" to solving health problems in communities and states. No one profession or group can do the job alone, he said. Accordingly, the PHS and HEW strongly favor the partnership method. Dr. Burney also noted there were "shortages in all types of health personnel," but he was confident some of the health bills passed by the last Congress would alleviate the situation.

Dr. Martha Eliot, chief of the Children's Bureau, cited an accelerated trend toward an integrated medical and educational approach in treating crippled children. She placed in this category cerebral palsy, sight conservation, cleft palate, hearing impairment, congenital heart disease, epilepsy, and orthodontic defects. "If we are to do the maximum job of rehabilitation for children and adults, we must somehow weave our medical and orthopedic clinics, our sheltered workshops, our dental clinics, or mental health clinics, our vocational rehabilitation and educational services into a coordinated and integrated program. We must see that they merge into a smooth-flowing rehabilitation program for our handicapped citizens, adults and children alike," Dr. Eliot declared. Mary E. Switzer, head of the Office of Vocational Rehabilitation, said the HEW "approaches the problem of disability as a challenge to our ingenuity, our courage and our willingness to see a difficult problem through."

AEC RESEARCH GRANTS

Among recent research grants by the Atomic Energy Commission were 22 awards, totaling $354,400, to medical institutions. The contracts are part of the AEC's program to assist research and development in fields related to atomic energy. The University of Michigan received the largest award ($20,000) of the three new contracts in the medical sciences. It will be used for studies with an x-ray monochromator and

---

From the Washington Office of the American Medical Association.

x-ray irradiation service operation. New York University's Bellevue Medical Center was granted $18,975 for research in the distribution and persistence of radioactive aerosols in the lungs of animals. An award of $10,000 will be used by Wayne University to study the effects of maternally administered phosphorus-32 on fetal and postnatal development of the rat. The AEC renewed 19 medical basic science contracts, totaling $305,425, the largest, $50,000, going to the University of Michigan.

RUSSIAN MEDICAL RESEARCH

A new program to keep American scientists up-to-date on Russian medical research findings has been started by the National Institutes of Health, using $250,000 appropriated by the last Congress. Soviet scientific information in the biological and medical sciences will be translated and distributed. Initially two Soviet medical journals, *The Soviet Medical Reference Review*, and a limited number of monographs will be reprinted in English and distributed to medical and scientific libraries, and to government agencies. These reprints will also be available for purchase. Plans are being made for the publication of a Russian-English medical dictionary and a directory of Soviet medical and biological research institutes. The National Science Foundation conducts a similar program in physical sciences.

PUBLIC SAFETY IN THE NUCLEAR INDUSTRY

Atomic Energy Commission official concerned the insurance aspects of radiation hazards has led out the government's position on public safety in the nuclear industry. W. J. Satterfield Jr., chief of the AEC insurance section, said the ultimate safety of the public is dependent on a program that (1) makes an extremely careful and detailed evaluation of every nuclear reactor to assure that all possible hazards have been recognized and defined; (2) assures that all reasonable steps are taken to minimize the probability of the occurrence of an accident; (3) relies heavily on the technical competence of the designers and operators of the reactor and of those making the hazard evaluation, and on the administrative and management abilities of the operating group; and (4) continually checks on the activities of the reactor operator for compliance with the rules of the AEC and the conditions of the license.

The official said one of the most difficult problems is the ultimate disposal or "actual return to nature" of radioactive wastes. Storage, he said, is expensive and in itself is a possible hazard. "On the other hand, unless the waste material is returned to nature in certain specific ways the natural physical, chemical and biological phenomena may conceivably result in undesirable situations. The AEC is currently sponsoring research and development of better waste handling methods at many sites." He cited these figures on the safety record in the federal atomic energy program from 1943 to 1955: out of 184 fatal accidents in over 2,500,000 manhours of work, only 2 were from radiation and those had nothing to do with reactor operation.

WORKSHOP IN ANESTHESIOLOGY

The first national postgraduate workshop in anesthesiology will be held at Walter Reed Army Medical Center in November. About 50 Army nurses will discuss the educational, professional, and personnel aspects of anesthesiology. . . . The federal hospital officials are now meeting at the 13th Interagency Institute for Federal Hospital Administrators at the Walter Reed Center. The latest management methods and techniques in administration providing better patient care are being discussed in the three-week program. . . . The United States Air Force has announced that 180 of its physicians have started residency training and 155 are in internships. Approximately two-thirds of the latter will be trained in civilian hospitals. . . . The Army has issued a new brochure on its Medical Intern Program. The pamphlet, designed to bring young graduate doctors into the program, lists the qualifications necessary for acceptance and discusses the facilities of the eight hospitals where the program is in operation.

MISCELLANY

Under the Professional Nurse Traineeship Program of the Public Health Service, 650-to-700 graduate nurses will be assisted in further education this year. Nearly 2 million dollars have been granted to 56 schools of nursing and public health. . . . The newest member of the National Advisory Cancer Council is Dr. J. F. Ross, associate dean of the school of medicine, University of California. The council, which advises on research activities of the National Cancer Institute, has 12 members—6 leaders in science and 6 leaders in education and public affairs. . . . The Food and Drug Administration announces that tranquilizing drugs for use in animals will be restricted to professional veterinary use to prevent possible unsafe diversion to human use. . . . The FDA seized seven shipments of drugs last month because the potency was not stated on the labels and five shipments because of false labels.

Intraperitoneal Air.—The finding of free intraperitoneal air on the roentgenogram has come to be considered a sign of a perforated gastrointestinal tract. Not only practicing physicians but textbook authors, as well, consider free subdiaphragmatic air as pathognomonic of perforated peptic ulcer. Undoubtedly, perforated peptic ulcer is the most frequent cause of free intraperitoneal air in patients with abdominal complaints, but a number of other, often recognized, conditions also present this roentgen finding. Some occur frequently, some rarely, but each is of sufficient importance to be thought of by the radiologist. . . . The most frequent artificial introduction of air into the abdomen occurs at the time of abdominal surgery. The presence, but not the duration, of air under the diaphragms may be predicted whenever the abdomen is surgically explored. Most investigators estimate the maximum persistence of air as being two to three weeks, but one observer extends this period to from four to six weeks. A full therapeutic pneumoperitoneum has been known to take eight weeks for absorption, so this latter figure is not unreasonable, particularly in view of an abnormal peritoneal surface. In the first few weeks postoperatively, free air alone cannot be considered evidence of perforation or reperforation of an ulcer, leakage of a suture line, or intestinal necrosis. The decision to reexplore the abdomen will rest on clinical evaluation, not on the unsupported roentgenologic finding.—H. W. Fischer, M.D., Free Intraperitoneal Air, *The American Journal of Roentgenology, Radium Therapy, and Nuclear Medicine*, July, 1956.

HEALTH HABITS AND HEART DISEASE—CHALLENGE IN PREVENTIVE MEDICINE

Edward P. Luongo, M.D., Los Angeles

• *A comparison of health habits has been made between a test group of 100 patients with manifest coronary disease and a contratest group of 200 people with the same distribution of ages and occupations but without coronary disease. The importance of dietary habits is illustrated by the finding that only 27% of the test patients had average diets with a variety of food and an apparent balance between caloric intake and energy output, while 60% of the contratest group had a satisfactory nutritional status. The exercise patterns differed significantly also, with 70% of the test group showing no regular exercise patterns either at work or away from it, as compared with 30% of the contratest group. No influence of tobacco or of alcohol was evident in this study, but, among the patients who survived a coronary attack, 71% have been using alcohol in moderation anywhere from 1 to 10 years since the attack, and in this group all claim beneficial effects with less anxiety. Stress patterns were found to be important, but occupational titles were not reliable as indicators of occupational stress. Preventive measures should be taken if the heart rate and diastolic pressure show a sustained rise, regardless of electrocardiographic findings, and such measures become urgent if there is hypercholesteremia, xanthomatosis, or diabetes. There is evidence that the real culprits in coronary disease are not hard work, overexercise, or occupational stress but sedentary living and poor health habits.*

Many leading cardiologists[1] believe that health habits, including nutrition and exercise patterns, are important factors in the prevention and postponement of coronary disease. This opinion received further support from preliminary observations in a study of 100 proved cases of manifested coronary disease compared with 200 control cases of patients in the same age group. The cases studied included anterior myocardial infarctions (42.5%), posterior myocardial infarctions (37.5%), angina pectoris (16.25%), and myocardial insufficiency (3.75%). These were compared with a control group of patients with no clinically manifested coronary disease, with approximately the same occupational distribution. All patients in each group were in the fourth or fifth decade of life. There was one female in the group with coronary disease and none in the control group. Clinical diagnoses in the coronary group were confirmed by at least one and in many instances two cardiologists. Many of the patients were studied further after recovery from the attack by the work classification unit of the Los Angeles County Heart Association. Cases in the study represent 100 out of approximately 160 known cases that have occurred in an employee population of 6,000 over a 10-year period. Of those coronary patients surviving (82%), 50% returned to their regular occupations and the rest to limited duty jobs. About one-half of these employees have been working 6 to 10 years since their attacks.

Nutrition

The study suggests strongly the role played by total caloric intake as a factor in the problem of prevention and postponement of coronary disease. Dr. Frederick Stare has stated that "nutrition is the most important environmental factor affecting the health of our population today."[2] Since 1948 I have been part of a preventive industrial medical group that has emphasized the importance of control of obesity and overweight among all our employees. In the majority of cases of overweight patients we have stressed the need for regular, moderate exercise as an important aspect of weight reduction. We feel also the most practical advice to employees is to "cut down" and not "cut out" foods. Bathroom scales at home and weighing scales available in the medical department have proved valuable psychological adjuncts to this program. Rapid eating is advised against in counseling overweight employees, since this interferes with adequate rise in blood sugar level, which in turn controls the appetite through the hypothalamus in the brain. Many rapid eaters have poor dental hygiene; they believe that the sooner they can finish masticating food the better, and, as a result, they gulp food rapidly. Dental hygiene, therefore, is a factor in weight control. By these

---

Chairman's address, read before the Section on Preventive and Industrial Medicine and Public Health at the 105th Annual Meeting of the American Medical Association, Chicago, June 13, 1956.

simple methods we have been able to reduce the incidence of overweight from 25% of the employee population in 1951 to 15% in 1955.

In the medical histories of those cases of manifested coronary disease studied, in more than two-thirds of the cases the total caloric intake was more than that necessary for the energy expended either on or off the job. More than two-thirds of the patients with coronary disease were overweight or obese on the average of 10 to 15 years prior to the attack, while in the control group of the same age range, only one-third were obese or overweight 10 to 15 years prior to this study. Only 27% of the patients with coronary disease had average diets with a variety of food, and in these apparently there was a balance between the total caloric intake and energy expended. These individuals had been able to maintain average or ideal weight 10 to 15 years prior to attack. By comparison, in the control group 60% of the patients had had average diets with maintenance of weight at average or ideal levels 10 to 15 years prior to the study.

Exercise

There was a close correlation between overweight, excessive total caloric intake, and lack of exercise patterns in the coronary group, with 70% showing no regular exercise patterns either at work or away from the job. Approximately the same percentage of patients were overweight due to excessive total caloric intakes. In contrast, only 30% of the control patients had no regular exercise patterns, and the records of these patients show the same correlation as to overweight and lack of exercise. These findings tend to support the present concept that exercise is an important aspect of weight control, and the lack of it, along with other factors, may cause predisposition to coronary disease.

Tobacco

Since the introduction of tobacco into Europe, soon after the discovery of America, its relationship to health and morals has been a controversial subject. In spite of various denunciations through the centuries by medical men, churchmen, and others, the smoking of tobacco continues to enthrall a considerable proportion of people in our culture. To date there is no convincing evidence in the literature that smoking of tobacco has any effect in accelerating sclerosis or in producing coronary disease.[3] In this study we found the consumption of tobacco was approximately equal in the coronary and the control cases, with 18% nonsmokers (mostly lifetime) in both groups. The rest (82%) in both groups consumed between one and one and one-half packages of cigarettes per day for a period of 10 to 15 years prior to attack or prior to this study. This would lend some support to the concept that tobacco is a nonetiological factor in coronary disease. It does not mean, however, that tobacco is without possible harmful or embarrassing effects on already diseased coronary arteries or, for that matter, on already diseased peripheral arteries.

Alcohol

As in the case of tobacco, the consumption of alcohol seems to have little or no relationship to the production of coronary sclerosis. The percentage distribution of those patients who did not use alcoholic beverages in any form was about the same (10%) for the coronary and the control group. In those patients who survived attack (82%), 71% have been using alcohol in moderation anywhere from 1 to 10 years since the attack. In this group all claim beneficial effects, with less anxiety. While one cannot relate any beneficial effects of alcohol directly to improved coronary blood flow,[4] there is evidence in the literature that in moderation alcohol may diminish the work load of the heart by reducing the pressure in the small peripheral arteries of the body. More important, alcohol in moderation may relieve anxiety through cerebral action. This anxiety frequently contributes to the onset of heart pain.

Occupation

Different occupations with different physical, emotional, and mental demands have been suspected as etiological factors in producing coronary disease.[5] The only conclusive effects seem to lie in the individual employee's health habits, including nutrition and exercise, and do not depend on job titles per se. If employees in sedentary occupations have poor health habits and do not have good exercise patterns, they may be expected to be more prone to coronary disease than employees whose work requires regular exercise and whose health habits, including nutrition, are good. In this study the occupational distribution of cases of coronary disease was approximately the same as the occupational distribution in the control group, taking into consideration the percentage occupational make-up of the total employee population. The incidence of manifested coronary disease was the same among executives, professional, clerical, and skilled workers, all doing moderate or sedentary work. The incidence among unskilled workers performing arduous work was lower compared to the other occupational groups. Occupational titles are unreliable from the standpoint of correlating epidemiological data with any conclusive effects of occupation. Further, in any true evaluation of these effects, we must be just as concerned with what an employee does away from the job as what he does on the job. I believe we can be certain that there is no evidence that physical exercise at work or play causes coronary disease.

Occupational and Nonoccupational Stress

Stress due to fears, phobias, frustration, anxiety, and fatigue certainly should be listed in the category of health habits, and its appraisal is an important part of any physical examination. Whether we consider stress, in the light of Cannon's theory of emergency epinephrine release, as a causative factor in heart disease or whether we consider stress as an expression of hormonal imbalance in the individual, we know that one of its frequent results is overeating. Individuals subject to nervous tensions, with feelings of frustration and suppressed hostility, at either an occupational, social, or domestic level, frequently find food, in nibbles or at a banquet, a relief from nervous tension. Stress, therefore, insofar as it causes overeating and overweight and affects the individual's outlook on healthful pursuits in life, must remain suspect in the etiological picture of coronary disease. In this study, obvious detectable stress patterns existed in most of the patients with coronary disease prior to the attack. These precoronary stress patterns were related more to cultural, domestic, and social problems than to the occupation. They were distributed over all occupational categories, with only a small preponderance in the executive group over the nonexecutive group. In the control group obvious detectable stress was about equal among clerical, professional, and skilled workers (30%) and lower among executives and unskilled workers (15%). Whereas 15% to 30% of the control group showed definite stress patterns, about 60% of all the patients with coronary disease had these patterns prior to attack.

Diagnostic Criteria Related to Prevention

Some comment is in order here on the reliability of of our present criteria and diagnostic techniques in determining the existence of diagnosable coronary disease and "nondiagnosable coronary disease" and determining presumptive evidence of candidacy for coronary disease. No doubt improved training of physicians and improved diagnostic techniques have brought about earlier and greater recognition of this condition in patients. We still have too many cases of patients with normal hearts who are on "the psychological scrap-heap" whose only indication of disease is that shown by the electrocardiogram. There is an inherent temptation for the medical profession, and for the public, to rely too much on some mechanical device, such as an electrocardiograph, not only in cardiovascular disease but in other diseases. At the other extreme, we have individuals with strong presumptive evidence of coronary disease who have been "ponounced perfect" on the basis of one electrocardiogram, frequently without the benefit of an exercise tolerance test. In the middle, we have the patients with clinically proved disease and a large number of younger candidates for the disease with only subtle subclinical findings that too often are disregarded.

Our increased knowledge of the disease has made little difference in the prevention of the disease among these candidates.[6] In this connection, waiting for presumptive evidence of the disease on the electrocardiogram often is too late. In our study, among those patients with coronary disease who had two or more electrocardiograms within six months to two years prior to attack, 50% had normal findings. In the control group 68% had two or more normal electrocardiograms six months to two years prior to this study. Thirteen percent had abnormal electrocardiograms with T-wave abnormalities and "nonspecific" changes.

Progressive Rise in Pulse Rate and Diastolic Pressure

We were able to observe some interesting correlations regarding pulse and diastolic pressure changes in the two groups over periods of 10 to 15 years. Over two-thirds of the patients with coronary disease showed a sustained rise in pulse rate (15 to 30 beats per minute) and diastolic pressure (10 to 30 mm. Hg) on the average of two to five years prior to attack. By contrast, only one-third of the control patients showed significant changes in pulse rate or diastolic pressure two to five years prior to this study. Preliminary observations suggest that these pulse and diastolic (with or without systolic changes) pressure elevations, correlated with findings on nutrition, stress, and sedentary habits, are important presumptive evidence of candidacy for coronary disease, and patients in this category should be treated as such by proper preventive measures, regardless of electrocardiographic findings. Preventive measures are even more urgent when these patients also show evidence of hypercholesteremia, xanthomatosis, and diabetes. In this study, 37% of the patients with coronary disease showed evidence of metabolic disorders as compared to 14% in the control group.

Obviously some of the patients in the control group are candidates for coronary disease at a later date, even if proper preventive measures are taken. However, we hope that these cases can be prevented, limited, or postponed as long as possible. This in effect is the challenge to all of us in preventive medicine, whether we be in public health, aviation medicine, or occupational medicine; whether we be in general or specialized medicine; or whether we be teachers.

Comment

There is evidence that sedentary living and poor health habits are the real culprits in coronary disease and not hard work, overexercise, or occupational stress. The disease incidence does not appear to be governed by occupational titles but more by what exercise an individual gets on or off the job and what his nutritional status has been 10 or 15 years prior to his fourth or fifth decade in life. It appears that insofar as proper health habits (including nutrition and exercise) are concerned, individuals should start training for middle and old age during their youth or childhood. Equally important, every individual should carry on these patterns of nutrition and exercise, within the realm of common sense, as long as possible in middle and old age. This may be difficult because of stresses, cultural problems, and economic situations later in life.

Preliminary findings of the study suggest the importance of appraisal of health habits as an integral part of every examination, in both industrial and private practice. Also, they reemphasize the importance of regular periodic examinations as a means of limiting and postponing the number of cases of coronary disease occurring prematurely in patients in the fourth decade of life. Physicians, in the future, will need more scientific and systematized information on positive health measures as they relate to normal nutrition and the tailoring of individual exercise patterns. Also, in order to prevent or postpone coronary disease, physicians must have time in their offices to appraise life interests and cultural pursuits of patients for whom they are responsible.

This study and others are reemphasizing the need for continuing research on nutrition as it relates to chemopathology and molecular disease. In this connection we have no positive criteria for prescribing diets for the prevention of atherosclerosis. While the work being done on the relationship of fatty acids to blood lipids[7] seems to open up avenues for research that may be productive of certain criteria, we find that the safest and most practical dietary advice is to "cut down" and not "cut out" and to encourage a variety of food in the diet with a restriction on unwarranted or excessive use of total fat. This would not apply, of course, to those with excessive amounts of cholesterol in their blood. To our best knowledge today, these candidates for coronary disease should become vegetarians.

Presumptive evidence in the form of abnormalities on the electrocardiogram usually comes too late for effective preventive measures. Progressive elevation in pulse rate and diastolic pressure in overweight men in the fourth and fifth decade of life is probably as good a criterion as the electrocardiogram for instituting preventive measures related to health habits.

Conclusions

It is hoped that this preliminary report will assist in the stimulation of other epidemiological studies on heart disease, in both private industry and other organizations where sufficient data are available. We will continue to obtain epidemiological data on present and future known cases. We and our predecessors in preventive medicine accepted the challenge of controlling morbidity and mortality due to infectious diseases. Our successful effort in this field has added to the longevity of man's existence on this earth. We have more men and women reaching middle and old age when coronary and other degenerative diseases are more prevalent.

We can add further longevity and, more important, breadth and depth to man's existence by thinking more in terms of positive health measures and by inculcating into our philosophy of medicine a new definition of health—one that is independent of the word disease and one that stresses good physical and mental health habits early in life that can be productive of better mental and physical efficiency in middle and old age. We must exert a continual alertness for new cultural problems with new habits, excesses, deficiencies, stresses, and strains that can rob us of our victory over the infectious diseases by taking lives of those recently saved from curable and preventable infectious diseases.

Everywhere the wonder of technicological advances goes, striking shackles from 100 men at each step and making mechanical horsepower and brain power cheaper than the humblest brawn. More and more men will be freed of certain distasteful and obnoxious labor and will have more time and money for leisure. Will this leisure be productive of a fuller life with more positive health? Already we have evidence that coronary disease in a sense is a "disease of prosperity," having no respect for any social or occupational class.[8] Here is our modern challenge. We in medicine as part of a creative minority can meet this challenge. We can do this if we discard outdated notions of what is health and what is disease. If we can guide men in the intelligent use of their abilities, resources, stamina, and interests in life, we can help them lead satisfying and happy existences.[9] If we as part of a creative minority fail, we will find ourselves part of a civilization unprepared for the economic riches it fought so hard to obtain.

DIVIDING LINES IN SPECIALIZED MEDICAL PRACTICE

J. Walter Wilson, M.D., Los Angeles

• *There are no rigid dividing lines in medical practice to which a physician is compelled to conform. The American boards, while limiting the practice of their diplomates, do not actually specify the boundary of limitations. Training and dexterity should be the basis for the doctor setting his own perimeter of practice. Dermatological practice provides perhaps the best example of the lack of dividing lines in its relationship to all the other fields of medicine.*

Practically as old as civilization itself is the phenomenon of specialization, by which certain individuals limit their activities to a small segment of the sphere of human endeavor in order that they may thereby be able to acquire a more thoroughly encompassing knowledge and a greater degree of skill. Even when the sum of all the facts previously learned by the race was yet small there was a surprising variety of occupations, each of which attracted its share of practitioners by presenting an opportunity for them to exploit advantageously certain of their own physical or mental attributes, such as those of size, strength, acuity of one or more of the senses, dexterity, or intelligence. The dividing lines between such specialties were thus quite naturally rather sharply delineated, since each demanded that an apprentice must possess a certain set of inherent attributes if he were to succeed. Because of this sort of natural, automatic selection, specialization has almost always been beneficial to humanity, and its influence has been responsible for an overwhelming proportion of all progress.

In medicine, the earliest historical records reveal that specialization had already developed to a considerable degree. No more than a brief glance back-

Chairman's address, read before the Section on Dermatology at the 105th Annual Meeting of the American Medical Association, Chicago, June 13, 1956.

ward through the centuries will prove that it is incorrect to refer to our own times smugly as "the age of specialization." Studying bones recovered from early Stone Age strata, LeBaron found the skeletons of 18 men who had had fractured limbs, only 3 of which would be considered to have healed poorly, even by today's standards, thereby indicating that there were persons then living who had become expert at setting fractures. According to Herodotus, there were in early Egypt special physicians for every part of the body. One of the earliest of the Egyptian papyri, dated about 2000 B. C. was devoted to disease of women, and another, concerned exclusively with surgery, appeared about 1600 B. C. Imhotep became famous for his ability to cause people who were in pain to be able to sleep, thus probably deserving to be called the first anesthetist. The greater part of Aesculapius' fame was as a military surgeon. Today, a Hippocrates would probably be called an internist especially adept at differential diagnosis, while a Galen would be sought after as one best able to select and guide therapy.

However, the dividing lines between these medical specialties were not as sharply drawn as in other fields of human endeavor. In today's vernacular, the ancient men of medicine would all be classed as general practitioners, some of them giving "special attention" to a particular field. Indeed, it is difficult to see any of the reasons why they elected to narrow their practices at all, beyond the fact that an appealing opportunity to do so must have appeared at an appropriate time.

It is equally difficult to discuss the boundaries of the medical specialties as they exist today, or the reasons why an individual selects one as his life's work in preference to the others or to an unlimited form of practice. It must be granted that there are certain phases of medicine in which great physical strength and stamina are useful assets to the operator, some which demand of him a greater than average degree of emotional imperturbability and some in which exceptional dexterity is an advantage; but, in general, anyone capable of becoming a practitioner of medicine at all could probably succeed as a specialist, if the desire and the opportunity were present at the proper time.

It is probably correct to state that even today there are no rigid boundaries whatever to any of the medical specialties. Each practitioner apparently guides himself according to his own interpretation, insofar as he is permitted to do so by his conscience and by the pressures brought to bear upon him in his own locality by others who practice his specialty and by his competitors in other fields. Even in different geographical areas of the United States there are wide variations in these boundaries. Each of the American boards in the various specialties requires its diplomates to "limit their practice" to that respective field, but nowhere are these boundaries specified by these organizations themselves. Thus, no specialist knows exactly what his limitations are supposed to be.

It is at this point that I must emerge as a partisan and, henceforth, speak as a dermatologist, for I believe that there are several reasons why it is singularly appropriate for a dermatologist to present this subject, not because he is capable of being less prejudiced, but on the contrary because he cannot avoid being biased in every conceivable direction. This is caused by the fact that dermatology is unique among the specialties in relationship to all dividing lines. Every other specialty has one or more of the segments of medical practice that it is undisputedly permitted by all other specialties to call its own. For example, no one but a highly qualified ophthalmologist attempts to remove cataracts or to graft corneas; all such cases are gladly conceded to him. Fenestration operations belong exclusively to otologists and cases of brain tumors to neurosurgeons, but even the most complicated of dermatological techniques is considered by the nondermatologist to be either entirely unnecessary or so simple as to be within his reach the first time he attempts it. Conversely, no specialty other than dermatology can say that its field is encroached upon in at least some degree by every other specialty. As an illustration, it would almost certainly be impossible to discover any practitioner of medicine who could honestly say that he had never once in his career attempted to treat a skin disorder.

Mechanisms Utilized in Dividing Medicine into Specialties

To a large extent the overlapping between specialties is due to the fact that in dividing up the ailments that can afflict the human body there is much disagreement as to which of several entirely different sets of rules should govern. For example, one method of division is based upon the belief that each specialty should concern itself exclusively with a certain area of the body; another places its emphasis almost entirely upon different forms of treatment; and a third considers the type of disease of paramount importance.

The first group of specialties named aboved may be termed "topographic," "regional," or, perhaps, "organic." Practitioners of one of these specialties limit their activities to the care of abnormalities involving only a certain area of the body, a certain organ, or a certain group of allied organs. By such a limitation, they consider themselves able to become expertly acquainted with all of the disorders that may be encountered in that region, rare as well as common, and to differentiate between them. They also claim to have mastered all of the methods by which these conditions should be treated, including the techniques involved in the use of whatever mechanical or electrical appliances may be required. Several of these specialties may be said to be "complete," because within the selected area both the medical and surgical aspects are covered. This group includes dermatology, urology, orthopedics, gynecology, proctology, ophthalmology, otology, and rhinolaryngology. Perhaps dentistry should be included here. There are other specialties, which we may class comparatively as "incomplete," whose perimeters are determined similarly by topography, except that in each instance there is a sharp division into two subsections, one surgical and the other medical. Here are included such pairs as neurology and neurosurgery, cardiology and heart surgery, pulmonary diseases and chest surgery, and gastroenterology and abdominal surgery.

In searching for an analogous mechanism of division in other fields of human endeavor, it appears that this method of grouping resembles somewhat that of the

Congress of Industrial Organizations among the labor unions in America, in which one of the important criteria for being included in membership is where the work is to be performed. For example, all persons employed in a certain locality, as in an automobile factory, are members of an automobile workers' union, regardless of the type of work each individual performs or the tools he uses. In the parlance of the labor unions, this is termed a horizontal type of organization. The analogy is not entirely correct, for there is a much higher degree of specialization among the workers within such a group than is found in the corresponding type of medical organization.

Based upon an entirely different concept is the mechanism of division in the second large group of medical specialties, in which the supremely important factor is considered to be the ability to use expertly a certain tool or class of tools or to administer a particular type of treatment, without regard to the region of the body involved or the kind of disease present. In this category are experts such as surgeons with scalpel and suture, radiologists with various forms of radiant energy, pathologists with laboratory apparatus, and physical therapists with their several modalities. Here there is a clear analogy with the craft guilds of the American Federation of Labor, represented by experts such as carpenters with saw, plane, and hammer; plumbers with die and wrench; machinists with lathe, drill, and mill; and musicians with various musical instruments. These pursue their particular crafts in whatever locality they may be required. Again using the vernacular of the labor unions, this mode of division is termed vertical.

The third group of medical specialties is delineated by placing the emphasis upon the type of disease that is presented, without regard to its topographic location or the sort of therapy that it demands. Here the best all-inclusive example is the oncologist, who claims ability to treat neoplasms without regard to where they may occur or with whatever modality is indicated, including surgery, radiation, or medication. There are a number of subgroups in this category, classed as less complete because the related surgery or radiation is not included in their respective fields, such as internists, epidemiologists, hematologists, allergists, endocrinologists, venereologists, and toxicologists. The analogous situation in nonmedical occupations is represented to a fair degree by such groups as policemen, firemen, Red Cross personnel, and, perhaps, termite-control specialists. An adjective bearing a geographical significance comparable to horizontal or vertical has not been applied here to my knowledge; perhaps the term "diagonal" is serviceable.

There are yet other medical specialties that are not suited to classification in either of these groups previously mentioned, such as psychiatrists, aeromedical personnel, and medical examiners for corporations or insurance companies. It is interesting to note a mode of division in medicine that depends entirely upon the age of the patients (pediatrics and geriatrics), which has no counterpart in labor unions unless it be to such classes as schoolteachers. Perhaps this method can be classed as representing a diagonal in yet another direction.

Divisions of Medicine as Observed in Actual Practice

It might appear that dermatology, being one of the topographic specialties delineated above, should not find itself in disagreement as to boundaries with the other members of that same group. This is not the case, for, as has been already pointed out, the boundaries of dermatology are encroached upon by all other specialties and it in turn encroaches upon each of them.

As an example, consider the boundary between dermatology and proctology. To the dermatologist there appears to be only one logical line of demarcation that needs to be considered, the mucocutaneous junction at the anus. It cannot be denied that from this point outward all that which is encountered upon the surface of the body is skin, subject to all of the diseases to which the skin in general is susceptible, in addition to a few that are peculiar to that area. Thus, it seems to the dermatologist that a physician must of necessity know the greater portion of the science of dermatology, if he is to claim the expertness expected of a specialist in assuming the care of an ailment external to the mucocutaneous junction. Yet some proctologists consider a circular area perhaps up to a dozen inches in diameter centered about the anus to lie well within their field. Dermatologists highly respect the ability possessed by proctologists to deal successfully with such conditions as carcinoma of the colon, fistula in ano, hemorrhoids, and prolapse, all of which require much specialized training and experience. It can be said with confidence that no one certified in dermatology attempts to treat such proctologic conditions. Realizing the importance of acquiring and maintaining skill in such valuable techniques, proctologists naturally devote all of their study time to them and are never found in attendance at skin clinics. Thus, they have no opportunity to learn to respect the difficulties of dermatology. As one example of the resulting lack of diagnostic ability, proctologic literature contains many discussions devoted to pruritus ani. It is obvious to the dermatologist that pruritus ani is not a disease and that it does not even deserve to be classed as a diagnosis, since it is only the translation into Latin of the symptom complained of by the patient. It is also obvious to the dermatologist that there can never be a single, truly successful treatment for pruritus ani, since there are altogether too many different causes that must be differentiated and specifically controlled. Proctologists treat many of these cases on the assumption that they are due to fungous infections, yet never bother to ascertain whether fungi are present. Dermatologists treat itching of the anal area only if there is a dermatosis visible that matches the symptom; otherwise consultation with a proctologist is advised. This is also their procedure when such itching does not subside quickly and simultaneously with the clearing of the dermatosis, since they realize that a deep-seated disease may easily have been the original cause of such a complaint. Dermatoligsts are firmly convinced that it would be better for such patients if proctologists would reciprocate by displaying a similar respect for dermatology.

Lest I be accused of inappropriately singling out proctologists for criticism, I hasten to add that each of the other topographic specialties has similarly included in its field a segment of the surrounding skin.

The skin of the perineum, groins, and pubic area, as well as that of a large part of the abdomen and thighs, is persistently treated by gynecologists and obstetricians. Except for cartilage, which is only infrequently susceptible to disease, the entire external ear is nothing but skin and the surrounding area is strictly a dermatological problem. Even the auricular canal is composed of modified skin. Yet some otologists still treat many cases daily of what they class by inspection alone as "fungous infections," even though it has long been known that fungi seldom cause disease in this area. Large areas of the skin surrounding the nose, mouth, and eyes are similarly included in the fields of endeavor of some rhinologists, laryngologists, and ophthalmologists. Many orthopedists customarily assume the care of the cutaneous surface of arms, hands, legs, and feet and internists that of the trunk. None of these practitioners devote any appreciable time to becoming acquainted with dermatological diagnosis or therapy.

With those groups that advocate dividing medical practice strictly according to the classes of tools that are to be used in the treatment of disease, the dermatologists have even more profound disagreements as to dividing lines. Perhaps the best example concerns the radiologists who frequently, and sometimes quite vociferously, express the opinion that dermatologists are straying inappropriately outside of their field by possessing and utilizing in their offices apparatus for the production of roentgen rays. In refutation, it is first necessary to point out that all of the early pioneers in roentgen therapy of the skin were dermatologists, and this science has been continuously studied and advanced almost exclusively by them ever since. Also, it seems obvious to the dermatologist that in order to treat a skin disease properly with whatever modality may be chosen, the diagnosis must first be ascertained, a procedure for which the roentgenologist is seldom if ever trained beyond the level of an intern. Even if the diagnosis is clear and x-ray therapy is actually indicated, the roentgenologist is unlikely to be able to bring a greater degree of skill to bear upon the administration of the therapy than the dermatologist, who devotes much more study time and practice to the roentgenologic aspects of strictly dermatological therapy. Furthermore, the dermatologists' x-ray machines are constructed especially for treatment of the skin and function better in that field than the all-purpose apparatus of the roentgenologist.

In spite of the high degree of ability to differentiate between tumors of the skin, that dermatologists acquire by intensive study, experience, and constant practice, their habit of subjecting every lesion to biopsy makes them aware of the inaccuracy of attempting such differentiation by visual means alone. Such histopathological study not only serves to distinguish between malignant and nonmalignant lesions but reveals a wide range of different types and degrees of malignancy, without which knowledge it is impossible to select the best therapy. Radiologists frequently administer x-ray therapy to lesions that they class as cancer by inspection alone and are later able to boast of high rates of cure by virtue of the fact that a large proportion of such lesions were in fact benign.

Wherever special clinics exist devoted to cancer, attended by specialists in all fields, it always becomes evident that certain cases are better treated by one modality than by another. From these studies, elaborate criteria have been developed upon which the selection of the therapy should be based. None of this experience is likely to be utilized in certain forms of medical practice, since it is beyond the realm of possibility when dealing with human nature to expect the roentgenologist to refer to the surgeon that half of the patients who come to him with cancer which can best be treated by surgery and expect the same consideration from the surgeon in return. The dermatologist has all methods at hand and is able, therefore, to act impartially, to the patient's benefit.

As to the dividing line between dermatology and surgery, there can be no quarrel with the opinion that no one should attempt any operative procedure that is beyond his training and ability, or which could, because of unexpected findings, lead him beyond his depth. However, it must be seriously questioned whether any surgeon actually believes that a dermatologist is less capable than he of performing the usual small dermatological surgical procedures. At times surgeons carry this view to absurdity by implying that the scalpel should be forbidden to all but fully trained surgeons.

With regard to the specialties devoted to a certain type of disease, a good example is oncology, which has set up its own dividing lines in the field of cancer. Where skin cancer is concerned, these lines are usually drawn to the exclusion of dermatologists. These oncologists claim to be expert in the diagnosis and therapy of neoplasms, without limitation as to the type of growth involved, its location in the human body, or the mode of treatment best suited to its eradication. To fulfill this claim would seem to demand a veritable constellation of superskills, combining clinical and histopathological differential diagnostic ability of the highest degree in all areas of the body, the combined dexterity of all of the other surgical specialties in their most difficult phases as presented by malignancies, and expertness in all types of radiotherapy and the use of drugs. Although it is probable that no one has attained this goal, it seems to me that such a Caesar, having eaten of special meat and grown so great, would find it too much below his dignity to quarrel over common moles and warts or small cutaneous tumors. To do so thereby would admit his inability to attract to his care a number of cases sufficient to keep him busy of the type for which he believes he is so well prepared. Whatever spare time he has would seem to be better spent in maintaining his astounding dexterity in so many directions.

Comment

I hasten to say that all of this encroachment does not dismay nor anger dermatologists nearly as much as might be presumed. They realize that such a large proportion of human illness involves the skin that there is still enough of dermatological practice left, in spite of all of the efforts of other practitioners. It has been said that, if the certified obstetricians were suddenly to be given the exclusive right to deliver all babies, as they frequently suggest would be appropriate, they would scream for help within a week. Similarly, dermatologists know that they could not care for all cases of skin disorders, even by working night and day. They do not resent the competition of other doctors who are able to succeed in rendering good service to patients with dermatological disorders. However, they see many examples of the harmful results of injudicious treatment, and from time to time they voice a warning.

Dermatological techniques in general lack the spectacular and obviously difficult facets possessed by certain phases of other specialties. Yet dermatology appears easy only to one who has not yet begun to study it. Having spent nine years in the general practice of medicine before beginning to specialize, I consider myself qualified to state that differential diagnosis and therapy in many phases of dermatology are at least as difficult as in any other branch of medicine, and no day passes without my reflecting wistfully that some other specialty would be easier. Dermatologists cannot understand how anyone who does not appreciate these difficulties and prepare to meet them by intensive study can hope to succeed in treating all diseases of the skin.

This paper is not intended to suggest that the perimeters of dermatology should be expanded. Dermatologists believe that the only appropriate boundaries are those that have always existed, rigidly established by the manner in which nature has for eons distributed skin over the human body. They are also satisfied with the way in which these perimeters have become accepted throughout the years by a large and growing proportion of the population and of the medical profession in general, which holds that complicated skin disorders of all kinds are best diagnosed and treated by skin specialists. They do not attempt, however, to force other doctors to conform to this opinion and usually comment on the subject only when it becomes necessary to refute what they consider to be unjustified criticism or to parry attempted interference with their proper functioning. I have tried here only to point out a few of the reasons why dermatologists are not willing to fold their tents and steal away, leaving all of the science of dermatology to be divided piecemeal among the other specialties, where it would always occupy a position of secondary importance and never receive the attention it deserves.

In general, it seems to be entirely proper that there are no rigid dividing lines in medical practice to which any doctor is compelled to conform. Each practitioner must set and observe his own perimeters, in a manner as unbiased as possible, by accepting only those cases for which he knows that his training and dexterity have prepared him to furnish the highest quality of medical care. If there must be dividing lines in medical practice, let them always be designed for the benefit of patients, not of doctors.

CONTROLLED RESPIRATION DURING CESAREAN SECTION

William K. Bannister, M.D., Hartford, Conn.

• *The condition and behavior of 418 newborn babies were studied after delivery by cesarean section, and comparisons were made according to the type of anesthesia received by the mother. Group 1 consisted of 96 mothers who received spinal anesthesia; group 2, of 165 mothers who received general anesthesia (thiopental sodium, cyclopropane with oxygen, and sufficient dimethyl tubocurarine to maintain a quiet operative field); group 3, of 157 mothers who received thiopental sodium, cyclopropane with oxygen, and enough of either dimethyl tubocurarine or succinylcholine chloride to allow complete manual control of the mother's respiration. Data on the number of minutes elapsing before the baby cried loudly permitted quantitative analysis of the results. The incidence and severity of depression in the babies was found to be least when spinal anesthesia was given. Comparison of groups 2 and 3 showed that manual control of the maternal respiration resulted in much less depression in the infants of group 3 than was seen in the infants of group 2, who were dependent on the spontaneous maternal respiration. When general anesthesia becomes necessary in obstetrics, the plane of anesthesia should be kept as light as possible, the duration of anesthesia should be as brief as good teamwork by obstetrician, anesthesiologist, and nurses will allow, and the mother's respiration should be supplemented by full control of her breathing, so as to ensure the best possible oxygenation with best possible elimination of carbon dioxide for mothers and babies.*

On Jan. 19, 1847, James Simpson administered the first recorded obstetric anesthetic when he gave open-drop ether to a mother during her delivery. Six years later, when John Snow gave chloroform to Queen Victoria during the delivery of Prince Leopold, the popularity of obstetric anesthesia was assured. Obstetrics was thus one of the earliest fields into which the anesthetic art was introduced. In spite of long experience, however, the field of obstetric anesthesia remains highly controversial. The place of general anesthesia in obstetrics, as opposed to regional methods, has long been a subject of debate. General anesthesia has many advantages. It is reliable and convenient. It is safer in the hands of the partially trained administrator.

On strictly scientific grounds, it is easy to condemn the use of general anesthesia in obstetrics because of its adverse effects on the newborn infant. This belief is strongly held in many teaching centers, and those who bear the responsibility of resuscitating asphyxiated babies usually agree. Hingson and Hellman have shown that neonatal mortality is not significantly influenced by the choice of anesthesia.[1] Lund has shown that the mortality rate for normal newborn infants is not greatly altered by different types of anesthesia but that the mortality rate for the premature and the distressed fetus is significantly higher when general

anesthesia is elected.[2] Evaluations of the mental development of children who were asphyxiated following delivery have been conflicting in their conclusions. Some recent studies have demonstrated little or no adverse results from asphyxia.[3] Although the sequelae of asphyxia may elude present investigative methods, common sense demands that hypoxia following birth be regarded as a hazard.

Selection of Cases

In order to study the depressant effects of anesthesia upon newborn babies, a group of patients has been selected in such a manner that causes of depression other than anesthesia might be eliminated from consideration. Injury and distress to the fetus during labor and delivery have been largely ruled out by selecting for study only babies born by repeat or elective cesarean section. All the infants were born of healthy mothers. None had any significant malformation that could be diagnosed, and all babies weighed 2,495 gm. or more. No twins were included. Premedication was uniformly secobarbital (Seconal), 100 mg. administered two hours before delivery, and atropine, 0.4 mg. one hour before delivery.

This method of selection was employed in order to obtain a group of newborn infants in whom any respiratory depression at birth would most probably be caused by anesthetic agents. Diagnostic techniques are not sensitive enough to reveal all abnormalities, and, no doubt, the criteria of selection were violated in some instances. The number of such abnormalities, however, should be few in number.

Methods of Anesthesia

Three types of anesthesia were administered for the cesarean sections selected for this study. Group 1 included 96 mothers who received spinal analgesia. Tetracaine (Pontocaine) hydrochloride and procaine were the agents used for all patients. Eleven of the mothers of this group received thiopental (Pentothal) sodium to allay anxiety. The largest amount of thiopental sodium given to any mother before delivery was 200 mg.

Group 2 consisted of 165 mothers who received general anesthesia, during the course of which spontaneous respiration was maintained. The agents employed were thiopental sodium, 100 to 150 mg., for induction followed by inhalation of cyclopropane and oxygen. A conscientious effort was made to maintain as light a plane of general anesthesia as was consistent with a quiet operative field. Tubocurarine chloride given in doses of 6 to 9 mg. was an aid in maintaining relaxation, in spite of light planes of anesthesia, and was used for all except three patients in this group.

Group 3 was composed of 157 mothers who received the same agents employed for group 2. The anesthetic technique was modified, however, to allow complete manual control of the mothers' respiration. Relaxant drugs were given three or four minutes following induction with thiopental sodium, 100 to 150 mg., in order to improve operative conditions and to insure complete control of respiration. Tubocurarine chloride was administered to 91 mothers in amounts ranging from 6 to 12 mg., and succinylcholine (Anectine) chloride was given to 66 mothers in total amounts ranging from 40 to 120 mg., given in divided doses. As soon as muscular relaxation was obtained, controlled respiration was begun and continued until the baby was delivered. Respiration was controlled by slowly increasing the pressure on the rebreathing bag during inspiration, followed by sudden release of the bag during expiration. A tidal volume of 500 cc. at a rate of 15 respirations per minute was considered to be adequate. An effort was made, and usually achieved, to acomplish hyperventilation in the mothers with an anesthetic mixture high in concentration of oxygen.

The only essential difference between the two methods of general anesthesia employed was that controlled respiration was used in group 3. The planes of anesthesia were the same in groups 2 and 3, as far as could be determined by clinical signs. The average length of anesthesia before delivery was 15 minutes in group 2 and 12 minutes in group 3.

Evaluation of Newborn Babies

The normal baby flexes its muscles, breathes, and cries immediately after delivery. This is the natural response to birth, and all the babies selected for this study presumably should have responded in this manner. Gasping and whimpering were not accepted as signs of normal response on the part of the baby. On the contrary, they were considered to be signs of distress. The length of time elapsing between delivery and loud crying was used in this study as a measure of the degree of depression of a newborn baby.

Results

Group 1.—Of the 96 babies in group 1, whose mothers received spinal anesthesia, 89 (92.8%) exhibited a normal response to birth during the first minute following delivery. Three infants (3.1%) cried loudly during the second minute after delivery and three (3.1%) during the third minute. Only one newborn infant (1%) in group 1 failed to cry lustily within five minutes after birth.

Group 2.—General anesthesia with spontaneous respiration was administered to the mothers of 165 babies in group 2. Eighty-nine of the babies in this group (54%) responded normally during the first minute following birth. Fifteen babies (9%) cried during the second minute and 20 babies (12%) during the third minute after delivery. A delay in lusty crying of at least three and not more than five minutes was observed in 26 babies (16%), and 15 babies (9%) required vigorous resuscitation for more than five minutes before they responded normally. Therefore, of the 165 babies in group 2, 41, or 25%, were depressed babies by any criteria and required resuscitation for more than three minutes.

Group 3.—General anesthesia with manually controlled respiration was administered to the mothers of 157 babies in group 3. One hundred twenty newborn infants (76.4%) in this group cried loudly within one minute after delivery. Ten babies (6.4%) failed to cry until the second minute after delivery, and 16 babies (10.1%) did not cry until the third minute. Eight babies (5.1%) did not respond normally until three to five minutes after birth. Only three babies (2%) failed to cry lustily within five minutes after being delivered. Serious depression of the newborn infant, as evidenced by a delay in lusty crying of more than three minutes, was present in 11 (7%) of the 157 babies in group 3.

Two relaxant drugs were administered to the mothers in this group. Sixty-six mothers received succinylcholine chloride, and 91 mothers received tubocurarine chloride. The two drugs were not followed by a significantly different incidence of depression lasting less than three minutes (see table). One baby failed to cry within three minutes following the administration of succinylcholine, while 10 babies failed to cry within three minutes following the administration of tubocurarine chloride. The experience with succinylcholine in only 66 patients is too limited to evaluate its usefulness in obstetrics. It would appear, however, to have no greater untoward effect on newborn infants than other muscle relaxants.

Crying Time of Babies Following Delivery After Administration of Tubocurarine Chloride and Succinylcholine

		Minutes					
Relaxant		1st	2nd	3rd	3-5	Over 5	Total
Tubocurarine	No.	67	6	8	8	2	91
	%	73.6	6.6	8.8	8.8	2.2	100
Succinylcholine	No.	53	4	8	0	1	66
	%	80.4	6	12.1	0	1.5	100

Comment

Hypoxia has been shown by Taylor and his associates[4] to occur in newborn babies whose mothers received inhalation anesthesia for their deliveries. It is logical to assume that hypoxia can produce depression of the fetal respiratory center and contribute to the incidence of asphyxia neonatorum. The results of this study support such an assumption.

Control of maternal respiration ameliorated the undesirable effects of general anesthesia upon newborn babies in two ways. Adequate maternal respiration assured an adequate supply of oxygen and removal of carbon dioxide with demonstrated advantages accruing to the infants. The average duration of anesthesia before delivery, when controlled respiration was employed, was 12 minutes, while the average period of anesthesia, when spontaneous respiration was maintained, was 15 minutes. This shorter period of anesthesia may also have been a factor in reducing the respiratory depression in the newborn infants of mothers managed under controlled respiration.

The technique of administering general anesthesia with controlled respiration, which is presented here, was not without its pitfalls. Difficulty in maintaining an adequate airway was the most dangerous of these and was encountered on six occasions. Depression of the newborn infant was noted each time this complication occurred, presumably because of hypoxia and hypercapnia. Endotracheal intubation of the mothers was avoided because it was feared that a period of hypoxia during insertion of the catheter would have a deleterious effect on the babies. In retrospect, intubation seems at times to be the lesser of the two evils and should be employed when it is clearly indicated. On the other hand, most young mothers can be managed easily without endotracheal tubes, and the hazard of intubation can usually be avoided. The danger of inflating the stomach is always present when controlled respiration is maintained without intubation. No harm to patients resulted from this complication. It was found that the pressure on the rebreathing bag could be controlled to keep this complication to a minimum.

Techniques of administration similar in some respects to the method of controlled respiration used in this study have been reported by several authors.[5] Some anesthesiologists prefer to use other agents, some prefer to intubate more frequently, and some reject general anesthesia entirely in obstetrics. There are occasions, however, when general anesthesia is indicated for obstetric procedures. When this occurs, three rules should be observed. The plane of anesthesia should be kept as light as possible. The duration of anesthesia should be as brief as good teamwork by obstetrician, anesthesiologist, and nurses will allow. The mother's respiration should be supplemented by full control of her breathing.

Summary

A group of mothers and newborn infants who were normal by all available criteria and who were delivered by elective or repeat cesarean section were selected for study. Three types of anesthesia (spinal, general anesthesia with spontaneous respiration, and general anesthesia with controlled respiration) were employed. Careful evaluation of depression of the newborn infants was recorded in each instance.

The incidence and severity of depression in the babies was found to be least when spinal anesthesia was given. The babies delivered of mothers who received general anesthesia and had adequate pulmonary ventilation by controlled respiration had a significantly lower incidence and severity of depression than the babies delivered of mothers who received similar anesthesia but who did not have their respirations controlled. It is postulated that better oxygenation combined with better elimination of carbon dioxide for mothers and babies contributed to this result.

FIVE-YEAR STUDY OF BENZTROPINE (COGENTIN) METHANESULFONATE

OUTCOME IN THREE HUNDRED TWO CASES OF PARALYSIS AGITANS

Lewis J. Doshay, M.D., New York

• *Benztropine, a synthetic drug with anticholinergic, antihistaminic, and sedative actions, was administered by mouth to 302 patients with various forms of Parkinsonism. The drug was found to have peripheral curariform effects that are long-lasting, cumulative, and very useful. Doses of 5 to 10 mg. thrice daily caused excessive flaccidity, to the extent that a patient was unable to lift his arm or raise his head off the pillow. Best results, in the control of rigidity, contracture, tremor, and insomnia, were obtained in the dosage range of 1 to 4 mg. a day for older patients and 2 to 8 mg. a day for younger ones. Abnormalities of gait, which troubled 56 patients, were alleviated in 35 of these. Three case histories are given to illustrate the relief from insomnia, night cramps, rigidity, and tremor, the recurrence of symptoms when the drug was temporarily withdrawn, the safety of continued use for more than five years, and the possibility of obviating side-effects, when they do occur, by simultaneous administration of phenindamine and trihexyphenidyl.*

Benztropine (Cogentin) methanesulfonate is a relatively new synthetic drug that has been used for the treatment of Parkinsonism. It has been under study by us at the department of neurology of the College of Physicians and Surgeons and the Neurological Institute of Presbyterian Hospital for more than five years but has been available to the trade only in recent months. A preliminary report of its use by me in 20 patients with paralysis agitans was made in 1952[1] and another report of its effect on tremor in 1953.[2] A considerable amount of literature has since accumulated.[3] However, because of misunderstandings as to posology, actions, and side-effects of the drug and because in a chronic ailment the long-term effects are as important as the immediate outcome, it was considered desirable to record our long experience with use of the compound in over 300 patients.

Chemistry and Pharmacology

Benztropine is tropine benzohydryl ether methanesulfonate. It was synthesized by uniting the tropine portion of the atropine molecule with the benzohydryl portion of diphenhydramine (Benadryl) hydrochloride to form a new product. Benztropine has the pharmacological properties of a powerful anticholinergic and antihistaminic agent in a single compound. The sedative effect of benztropine in experimental animals is about the same as that of tripelennamine (Pyribenzamine) hydrochloride but much less than that of diphenhydramine. Tests with animals proved it to be an extremely nontoxic compound.[4]

Benztropine

Material and Procedure

Benztropine was studied for therapeutic effects, side-effects, dosage, and method of administration in 342 patients. This report is concerned with only 302 patients, because 40 could not be followed up. Of the 302 cases of Parkinsonism, 65 (22%) were postencephalitic, 123 (41%) idiopathic, and 114 (37%) arteriosclerotic. There were 171 (57%) males and 131 (43%) females in the series. Forty-five per cent of the patients with postencephalitic paralysis agitans were in the 40-to-50-year age range, 50% of those with idiopathic disease were in the 50-to-60-year age range, and 67% of those with arteriosclerotic Parkinsonism were in the 60-to-70-year age range. Eighty-one cases were treated at Vanderbilt Clinic and 221 in private practice. The patients were unselected, except insofar as they presented symptoms that were uncontrolled by other remedies.

Benztropine is now available in 2-mg. quarter-scored tablets. Originally, it was administered by us, under the name of MK-02, in amounts of 5 to 10 mg. three times a day, in efforts to establish the limits of therapeutic safety. At such dosages it was found that severely rigid parts turned flaccid to the extent that a patient was unable to lift his arm or raise his head off the pillow. Further trials proved that best results are obtained in the dose range of 1 to 4 mg. a day for older patients and 2 to 8 mg. a day for younger ones. The drug appears to exert a peripheral curariform-like effect that is cumulative and long-lasting; hence, the

---

total daily dose may be administered once a day upon retiring. Although a powerful muscle relaxant, it lacks the cerebral stimulant action of other compounds, so that most patients require the administration of an additional drug such as trihexyphenidyl (Artane) hydrochloride, cycrimine (Pagitane) hydrochloride, or dextro amphetamine (Dexedrine) sulfate during the day for maximum benefits. The usual starting dose of benztropine is 1 mg. at bedtime for older patients and 2 mg. for younger ones, and this is progressively increased to the level of optimum effect or maximum tolerance, whichever comes first. Some patients prefer to use benztropine twice a day, with the largest increment at bedtime.

Patients were seen at weekly intervals at commencement of therapy and at longer intervals after the tolerance and response were established. They were under close supervision by telephone during the initial stages of therapy, so that changes in medication could be effected as required. Placebos were administered to some patients for control studies, and others were required to cease taking benztropine for a week at a time so that changes in their conditions could be noted. During visits at office and clinic, observations were made of improvements in behavior, speech, gait, rigidity, tremor, posture, and facial expression. Records were kept of information submitted by the patients and their families. Twenty of the patients were under treatment with benztropine as inpatients of the Neurological Institute, where opportunity was afforded for daily observation of its effects in comparison with effects of placebos and of benztropine in combination with other preparations. A patient's condition was classified as improved or unimproved. In previous studies evaluating the merits of anti-Parkinson agents,[5] it was found undesirable and unsatisfactory to delineate shades of improvement. Patients who gained remarkable relief from benztropine therapy were thus grouped along with those only slightly improved. Moreover, no patient was considered to be improved unless he had received the drug for at least four weeks.

Results

The results obtained with benztropine in a series of 302 cases of paralysis agitans, with the three types of the disease represented, were evaluated on the basis of the afore-mentioned criteria. A summary of the overall efficiency of the drug is presented in table 1. Here it is noted that the percentage of improvement was greater in the private than in the clinic patients (59% to 32%). In part, this was due to the fact that some clinic patients were seen by different physicians, some of whom were not fully acquainted with the new product and who hence shifted patients to treatment with more familiar compounds such as trihexyphenidyl. In other instances, the medicament, during the long course of a five-year investigation, would be changed from benztropine to other experimental drugs that were under special investigation at the moment. These situations were not likely to occur in private practice, where patients were seen year after year by the same examiner.

TABLE 2.—*Effects of Benztropine on Individual Symptoms of Parkinsonism (302 Cases)*

	No. Reporting Symptom		Improved		Unimproved	
Symptom	No.	%	No.	%	No.	%
Rigidity (contracture)	293	97.0	174	59.5	119	40.5
Tremor	255	82.0	85	33.4	170	66.6
Akinesia	114	37.7	35	30.7	79	69.3
Gait	56	18.6	35	62.5	21	37.5
Spells of "freezing"	53	17.3	37	70.0	16	30.0
Insomnia	51	16.9	29	57.0	22	43.0
Poor posture	38	12.6	16	42.1	22	57.9
Oculogyric disturbances	31	10.3	13	41.9	18	58.1
Sialorrhea	18	6.0	11	61.1	7	38.9

The best results (table 2) were obtained in the control of rigidity, contracture, tremor, gait disturbances, and insomnia. Gait was improved in 62% of the patients. The control of insomnia in 57% is probably attributable to the diphenhydramine component, which has a mild soporific action. Benztropine was found to exert a highly selective action against certain symptoms of Parkinsonism such as no other current drug affords. Chief among these were the fixed facies, dysphonia, dysphagia, faulty posture, muscle cramps, and "freezing" of the legs. Clinical experience in case after case served to prove that benztropine is the most powerful orally given antispasmodic for combating attacks during which the patient's legs become "glued to the ground" and efforts to free himself result in falls and injuries.

Trihexyphenidyl was the most common supplementary drug employed with benztropine (52% of cases). Cycrimine was added in 20% of cases and dextro amphetamine in 10%. Twenty-four patients received benztropine alone throughout the duration of treatment. A combination that proved to be well tolerated and helpful to patients of highly sensitive make-up included 2 mg. of trihexyphenidyl twice a day, one tablet of phenindamine (Thephorin) tartrate three times a day, and 1 or 2 mg. of benztropine on retiring. The fact that benztropine has to be used along with other drugs is no detriment, since it is well known[6] that in order to control the many symptoms of Parkinsonism one not infrequently has to employ several preparations at the same time. What is of prime concern to the patient is that he be made physically more comfortable and functionally more useful at home, at work, and in his social life.

The duration of use of benztropine is shown in table 3. Nine patients have received the drug for over four years. Considering that when the investigation commenced five years ago there were but 20 patients receiving benztropine, the fact that 9 patients (45%) have steadfastly continued receiving the compound reflects very favorably upon its value to them. Again, three years ago only 62 patients were under treatment with benztropine. Of this number, 41 (57%) have maintained its use for upwards of three years, which similarly reflects the long endurance of its good effects. As information accumulated with regard to its efficacy and safety, more and more patients were started on benztropine therapy, many of these during the past year. Under the circumstances, it is of no small significance that, even with the recently added patients, 42.1% of the entire series of 302 patients are listed as having continued with the drug for 18 to 24 months. It should also be noted that private patients continued benztropine therapy almost twice as long as clinic patients, for reasons already stated. It has been our experience that patients derive positive benefits from the new drug and hence continue taking it month in and year out. Even those that discontinue taking it for one reason or another soon find that no other preparation can reproduce its singular effects and thus resume treatment with it. There is little, if any, increase in tolerance, so that most patients do not require an increase in dosage with the passage of time. Since benztropine is administered but once a day, at bedtime, its administration is easily added to any medicinal program.

TABLE 3.—*Duration of Use of Benztropine Among 302 Patients with Paralysis Agitans*

Side-Reactions

No serious side-reactions appeared in any of the 302 patients. The chief side-effect has been dryness of the mouth (53.3% of patients). This is usually mild in nature and disappears after breakfast. In only 5.3% of of the patients was the dryness sufficient to require an adjustment in dosage. A macular skin rash appeared on the arms and legs of a few patients (1%). This cleared on temporary withdrawal of the drug or reduction of the dose. Weakness occurred with great frequency during the early stages of the investigation. However, it became apparent that this was due to the extraordinarily large doses that were being used, and after the dosage was reduced this symptom was not noted. Drowsiness, dizziness, or mental confusion were not encountered in the 221 privately treated patients. However, six such instances were recorded by different observers in the 81 patients treated at Vanderbilt Clinic. Slight nausea was present in 3.7% of the patients and blurring of vision in 3%. Benztropine showed no deleterious effect on the blood of 130 patients in whom serial studies were made. It can be said that benztropine is one of the safest drugs to use, because it causes minor, if any, blurring of vision, does not affect the blood, blood pressure, pulse, or heart, and does not produce drowsiness, dizziness, mental fogginess, or hallucinations such as not infrequently occur with other anti-Parkinson agents.[7] Benztropine is safe to employ in patients with glaucoma, because within therapeutic range the pupils are little, if at all, affected.

Report of Cases

The following cases will illustrate practical situations met with in the administration of benztropine and some of its effects and side-effects.

CASE 1.—A 56-year-old patient with idiopathic paralysis agitans had a six-year history of progressive bilateral tremor and rigidity, stooped posture, propulsive gait, frequent falls, insomnia, and mental depression. He had been treated with a variety of drugs, the last of them being trihexyphenidyl. He was particularly distressed by his inability to turn in bed or to get in and out of bed. His wife had to rise several times a night to get him safely to the bathroom. In April, 1951, he started taking 2 mg. of benztropine on retiring in addition to trihexyphenidyl during the day. A month later, the patient was able to walk with greater ease, his posture had improved, and he was happy to report that he was able to get in and out of bed by himself. His wife was especially pleased, because for the first time in years she was able to enjoy a full night's rest. He continued to maintain his improvement until recently, when some progression in rigidity made it necessary for him to take 1 mg. of benztropine at noon. There have been no side-reactions.

CASE 2.—A 64-year-old x-ray technician had idiopathic paralysis agitans of five years' standing, manifested chiefly in tremor and rigidity of the right side of the body. After unsatisfactory trials with other remedies, he started receiving 2 mg. of benztropine at bedtime in October, 1952, and reported remarkable control of his symptoms. His wife stated that with the new drug "her husband does his work regularly, is cheerful, active, visits friends, and converses easily, whereas previously his speech was thick, his limbs ached and cramped, and the tremor proved embarrassing to him." He made no complaint of side-reactions during any of his visits. However, in May, 1954, in the course of a routine blood check, it was discovered that he had chronic leukemia, with a white blood cell count of 86,000. Benztropine was immediately suspected by the patient, but further investigation proved that our patient's failure to employ necessary precautions in his x-ray work was to blame. With institution of rigid precautions, his white blood cell count returned to normal. He has continued to do well while receiving 2 mg. of the drug and has not needed to increase the dose or to add other preparations.

While in most cases benztropine had to be supplemented with other drugs, there were instances, such as in case 2, where patients employed benztropine alone with good effect. This case also serves to point up the lasting action of the dose given at night and the protection it affords the patients against tremor and rigidity throughout the succeeding day. The case further illustrates a ready tendency of patients to attribute all physical discomforts and disturbances, in this instance leukemia, to a new drug. Complaints patients require discriminating evaluation.

CASE 3.—A 58-year-old man had arteriosclerotic Par with typical onset of shuffling gait and rigidity o extremities in 1952. There was an antecedent hi en. Again we must in all fairness doff our hats to the practitioner whose vast knowledge of care of persons from infancy to old age is being greatly enhanced. Then, too, the various disciplines (specialties) of medicine have played a very impressive part in this vast kaleidoscope of medical care. It has not been too long ago that a fractured femur in an older person was a warrant either for his demise or, at best, for life in a chair or bed. Especially unpleasant were the experiences of the hemiplegic patient with aphasia who was considered mentally deteriorated; or the arthritic, a useless mass of vegetating humanity; or the amputee consigned to a chair for life, to be lifted from place to place. Often they had been handed from hospital to hospital, service to service, and from physician to physician until the lowest depths of physical degradation had been reached.

There remained but one course to follow, transfer to a public institution where lack of home comforts and curtailed (and even severed) contact with family and friends made for difficult adjustment. A tax-supported facility, the Woodville and Mayview hospitals of the Allegheny County Institution District, enlisting the aid of its staff, consultants, and community resources, has performed a magnificent feat of restoring many of the above-described "displaced persons" to home and community. These accomplishments, in brief, consisted of combining the expertness of all medical specialties where needed with the ancillary services so necessary in the program. Early ambulation for patients with fractures, graded activities for the hemiplegic, utilization of the remaining abilities of the arthritic, and training of the amputee to be self-sufficient were integral parts of the process. Here again is represented the factual status of rehabilitation for an aging population that will grow larger.

We also see the collective efforts of the medical profession, frequently criticized, infrequently praised, directed toward the ill and aging. This road has not been a smooth one. Progress is often obstacle ridden—which only makes for greater effort. There are many gaps in our efforts that will close as greater understanding gives us enlightenment. First, housing for the recovered older person is scarce and abominable. Discharge from a public institution is a ticket to a fourth or fifth-floor walk-up, cold flat; this "ascension" to higher levels is purely a monetary method of saving finances—the more stairs climbed, the cheaper the rent. It would appear that all housing projects should provide proper cover for these humans at a compatible rental. Second, far too often formerly disabled aging persons languish in "home departments" of public institutions. Many of these people are able to be up and about but have unfortunately acquired the institutional stamp as an easier way of life. There are, however, certain statutes that prevent their discharge, since suitable housing is unavailable and the desire to live independently has been lost.

Third, many public assistance bureaus act as fiscal agents, doling out finances to needy clients, whereas their prime function should be the maintenance of the older person in familiar surroundings outside a public institution. Fourth, occupational opportunities must be appraised by labor, industry, and community to lighten the financial burden, as well as enhance the dignity and self-sufficiency of these persons. Finally, the public must be educated to the understanding that age, even with disability, is not necessarily the last station before demise. This, by all odds, is the most difficult obstacle to surmount, but the concerted drive by medicine and its companions and the social, economic worlds of communication will eventually dispel the hopelessness, helplessness, and haplessness of our aging population.

In the immediate future a new institution for the chronically ill and aging will be completed. It is being built under the auspices of the government of Allegheny County (near Pittsburgh) and will embody the most modern concepts of medical care and architecture. Of course, obsolescence comes rapidly in this field. However, there will be adequate and complete medical facilities, opportunities for most of the facets of rehabilitation, recreational advances, and, above all, a structure built specifically for its planned purpose. This might be criticized by the smaller and less opulent communities, but it will be a model and may be adjusted to the needs of any locality. The team approach, the basis for the success of its original venture of physical rehabilitation of the chronically ill and aging, will be maintained and increased in scope.

Comment

The foregoing report sketchily represents 10 years' experience in the care of the aging and chronically ill, including visits to 200 or more institutions in this country and abroad. It is intended to point out the possibilities for physical redemption and morale resumption in a group who sorely need help. In the total consideration, those in physical medicine deserve commendation for their part. This mass effort belongs to no single group, since each is interdependent upon the other. Evidence favoring the physiatrist and his staff can be found not only in public and private hospitals but in Veterans Administration institutions, where separate services have been inaugurated to facilitate and make workable the expertness of all other specialties. The poorhouse ("gateway to oblivion") must give way to a more modern hostel where adequate and more all-embracing medical care must be available for better restorative services.

The specialists of medicine are working increasingly, delving into the mysteries of the aging process and prevention of physical catastrophies as well as the means of offsetting their undesirable sequelae. Those in physical medicine in particular are charged with the responsibility for putting into conjunctive action the expertness of their colleagues in all other specialties. Finally, this is a medical problem and, like all others preceding it, has challenged the tenacity and ingenuity of all who are directly or indirectly involved. This challenge will be met!

5722 Fifth Ave. (32).

SURGICAL TREATMENT OF HIGH-LYING GASTRIC ULCER

Richard K. Gilchrist, M.D., Chicago

• *Two varieties of surgical operation are applied to high-lying gastric ulcers. One consists in resecting the ulcer (if it is on the lesser curvature) with all or part of the lesser curvature and a sufficient part of the greater curvature to give a two-thirds resection; this is followed by repair according to either the type 1 or type 2 Billroth operation. The other consists in leaving the ulcer undisturbed, resecting the distal one-half or two-thirds of the stomach, and concluding according to either the Hofmeister or the type 1 Billroth operation; the ulcer heals without trouble in most instances. Both varieties of operation have given excellent long-term results. In either case, specimens of tissue must be obtained and examined for malignancy, which is the greatest problem in the treatment of high-lying gastric ulcers. The unexpected finding of malignancy by microscopic examination is most common in small ulcers. Concomitant gastric and duodenal ulcers are frequent, and among 98 cases of this kind there was marked retention. When obstruction occurs it must be relieved. The temporary insertion of a gastrotomy tube for feeding is to be considered if obstruction is severe, and a posterior gastroenterostomy may be advisable in poor-risk patients.*

The surgical problem in duodenal ulcer is a fairly standard one, and the diagnosis is usually clear-cut, except in an uncommon case where the source of hemorrhage is unknown. The types of operative procedures are standardized, with each one having numerous advocates who can quote a large collected series to show the results that can be achieved. The surgical problem in gastric ulcer, however, is not so well standardized; and there is a less clear-cut picture as to the most desirable treatment, particularly for the 5.5% of gastric ulcers that are found in the cardia.[1] The greatest problem is one of diagnosis; the question as to the differentiation between gastric ulcer and carcinoma is not completely solved except by microscopic section.

Incidence of Malignancy and Hemorrhage

Gastroscopic examination of 273 patients by Schindler and Desneux[2] resulted in a 7.3% diagnostic error. Eighteen benign lesions were diagnosed as cancer, and two cancers were diagnosed as benign lesions. In 14, the lesion could not be examined adequately. Ranson[3] reported that the surgeon found an unsuspected carcinoma in 10% of 188 gastic resections for benign ulcer. Caruolo, Hallenbeck, and Dockerty[4] reported 91 posterior wall peptic-type ulcers, which required sharp dissection to detach the ulcer base from adherent structures. Three of the 91 proved to be carcinoma. Twenty-six of 88 patients, or 29.5%, were thought to have carcinoma in view of x-ray findings. The final preoperative diagnosis was carcinoma in 36, or 40.9%, of the patients. But every one of these patients proved to have only a benign lesion, though three patients had total gastrectomy. Three others who did have carcinoma had free acid; the lesions of all these three had been diagnosed by x-ray as benign. Ivy,[5] in a special study on the presence of malignancy in gastric ulcers diagnosed as benign, found that 281 of 2,212 cases were carcinoma, an incidence of 12.7%. These examples simply emphasize the fact that not even the most experienced doctor can adequately differentiate between benign and malignant gastric ulcer on the basis of the patient's age, the clinical picture, the presence or absence of free acid, the gastroscopic or x-ray examinations, or surgical palpation and excision.

Numerous reports have emphasized the frequency of concomitant gastric and duodenal ulcers in patients requiring surgical intervention for peptic ulcers. Johnson[6] quotes Sir David Wilkie, who reported 42 of 300 personal cases in which combined ulcers occurred, an incidence of 14%. In Johnson's own series there were 29 of 311 cases, or 9%, of combined ulcers; Ranson[3] reported a 16.5% incidence of combined ulcers. In a series of 156 cases, I found combined ulcers in 12% of the patients. Johnson[6] found that the duodenal ulcer was discovered first in 79 of 98 cases, while the gastric ulcer was discovered first in only 6 cases, in 5 of which there was an old healed duodenal ulcer scar. There was usually hyperacidity, characteristic of a duodenal ulcer, in the combined cases. In 76 of 98 cases there was marked retention. I have had a similar experience, which has impressed me with the fact that duodenal obstruction increases the possibility of later development of gastric ulcer.

Free perforation of high-lying gastric ulcers does not seem to be common, though Meyer[7] reported that 49.5% of 700 perforated ulcers were in the stomach. Hayes[8] reported that only 2% of gastric ulcers with perforation as the presenting symptom were malignant, whereas 16% of all other gastric ulcers were malignant. While free perforation is not common, perforation into other viscera is not uncommon, the pancreas and liver being most commonly involved.

Many authors agree that hemorrhage from gastric ulcers is common. Johnson[6] reported that there was bleeding in 47% of those patients with combined gastric and duodenal ulcers. Taylor[9] found that five of eight acute gastric ulcers of the high lesser curvature hemorrhaged. Branwood[10] found that 84 of 116 bleeding gastric ulcers seen at the Royal Infirmary between 1944 and 1951 were benign and that in about one-half of the cases in which hemorrhage occurred and resection was not done there was a recurrence of hemorrhage. In Ranson's[3] series, 4.8% of the gastric resections were performed for hemorrhage.

had subtotal gastric resections for
fatal postoperative hemorrhage fr
o 7 cm. distal to the esophago

Read before the Section on Surgery, General and Abdominal, at Annual Meeting of the American Medical Association, Chicago, 1956.

Indications for Surgery

Perforation of gastric ulcers into the free peritoneal cavity is an indication for surgery, just as it is in duodenal ulcers. Severe hemorrhage may be an indication for urgent surgery. In the presence of severe bleeding of the upper gastrointestinal tract, where there are none of the signs of portal obstruction, I believe surgical intervention is indicated if the hemorrhage persists after 2,500 cc. of blood replacement. The operation is primarily to stop hemorrhage, though it should heal the ulcer also. The stomach must be opened widely and a search made for the bleeding point. Often this cannot be found, and a three-fourths resection is performed. If severe hemorrhage recurs in the postoperative period, reexploration should be carried out and all the stomach except a 1 cm. margin at the esophagus should be resected. I now know of four instances where this has been lifesaving.

The large adherent gastric ulcers pose a special problem. These usually have perforated so that the liver or pancreas makes up the base of the ulcer. The usual diagnostic aids are not reliable. However, a two-to-three-week course of intensive medical management, often using a milk drip at night, will promote healing. If healing is not complete within this time, surgery is indicated. Many of these patients are in the older age group and their acid values are low. Sometimes no free acid can be found by an Ewald test meal. Pain is not prominent in these large ulcers. A rapidly enlarging ulcer likely will be found, on x-ray examination, to be benign [12]; the large adherent ulcers are more apt to be benign than malignant. At the time of operation, the stomach should be opened and numerous biopsy specimens taken to determine the nature of the lesion, whenever there is doubt as to the diagnosis. In all cases in which gastric ulcers have not healed after three weeks of medical management resection should be done.

A review shows that in 75% or more of gastric carcinomas masquerading as benign lesions resection is possible and that 35% to 40% of those patients with such lesions survive five years after their operation. Thus, 30% of all patients with malignant ulcers with a preoperative diagnosis of benignancy are alive five years after operation.[13]

Types of Operative Procedures

There are two common operative procedures that are applicable to high-lying gastric ulcers. One of these, the operation of choice as reported by Johnson and Orr,[14] is the resection of the ulcer with all or part of the lesser curvature (if it is a lesser curvature ulcer) along with a sufficient part of the greater curvature to give a two-thirds resection. A Billroth 1 or 2 repair is then performed. Shoulders and Lischer [15] advised that the large ulcers be treated by a subtotal gastric resection. They recommend that the rim of the ulcer be resected but that the base should not be disturbed. Caruolo and co-workers [4] say that the surgeon faced with a case of large, fixed ulcerating lesion of the posterior wall of the stomach without signs of malignancy should remember that most lesions of this type are benign and they should, therefore, proceed with resection, whenever possible, thus avoiding the error of regarding the lesions as malignant and inoperable. None of their 91 patients with adherent ulcers of the posterior wall developed pancreatitis when the ulcer base was dissected off the pancreas. Waltman Walters [16] has said he prefers this type of operation. I have performed this type with complete satisfaction. Maingot [17] uses the Pauchet type of resection, which is only a little different, except that he cauterizes the remaining base of the ulcer if it cannot be removed.

The second most common type of operation, which was described by Madlener [18] in 1923, is popular in Europe. In this operation the high-lying adherent ulcer is not disturbed. The distal one-half or two-thirds of the stomach is resected, and a Hofmeister or Billroth 1 type of resection is performed. The ulcer site heals without trouble in most instances. Colp and Druckerman [19] strongly recommend this operation in poor-risk patients. With this operation Finsterer [20] reports an operative mortality of 5%.

With either type of gastric resection the long-term results have been excellent. Unsatisfactory results or occurrence of jejunal ulcer is uncommon after resection for gastric ulcer. For all types of gastric ulcer Ranson [3] reported only 5% poor results and 3% occurrence of jejunal ulcers. Other authors are in general agreement with him. Total gastrectomy may be performed, but it often disables the patient and should not be done if malignancy can be ruled out. If the patient is in poor condition, a simple gastroenterostomy may be an immediate way out. I have seen a patient with an immense, high-lying gastric ulcer that had the capsule of the liver as its base who recovered after gastroenterostomy and remained well for many years. A temporary gastrostomy tube may be placed in the normal part of the stomach to facilitate feeding when there is obstruction in the upper one-third of the stomach. Since wedge resection of the ulcer does not reduce the acidity or relieve obstruction, it is inadequate.

Summary

The greatest problem in the surgical treatment of high-lying gastric ulcer is the question of malignancy. Either the ulcer must be resected and examined microscopically or numerous frozen-section biopsy specimens must be examined to rule out malignancy. The large adherent ulcers are usually benign, and the unexpected finding of malignancy by microscopic examination is most common in small ulcers. In cases of severe hemorrhage the ulcer must be resected and the acidity reduced. Concomitant gastric and duodenal ulcers are common, and obstruction must be relieved in all cases. A two-thirds resection with resection of the gastric ulcer, which is the treatment of choice, will usually give good results. The Madlener operation, leaving the high-lying ulcer and performing a two-thirds resection of the distal portion of the stomach, has given good results for many. In poor-risk patients, it may be wise simply to perform a posterior gastroenterostomy, and, if there is a severe obstruction, to insert a temporary gastrostomy tube in the stomach for feeding purposes.

THERAPEUTIC EXERCISES IN MANAGEMENT OF PARALYSIS AGITANS

Donald J. Erickson, M.D., Edward C. Clark, M.D.,
Donald W. Mulder, M.D., Collin S. MacCarty, M.D.
and
Betty G. Clements, M.D., Rochester, Minn.

• *The prevention of progressive disability in a patient with paralysis agitans is dependent to a great extent on the patient's ability and desire to be active. The muscular rigidity, discouragement, and even depression so characteristic of this illness are not conducive to activity. The recent emphasis on medical and surgical therapy, which often are themselves palliative, has obscured the importance and often prevented the use of continuing exercise in the treatment of this disease.*

Specific exercises prescribed by the physician to prevent contractures and to increase speed of the extremities, along with correction of posture and training in gait, contribute much to the treatment of this disease. In addition, it is necessary to urge the patient to continue to perform the activities of daily living, as well as other tasks requiring use of his muscles, to prevent the deleterious effects of inactivity.

Paralysis agitans is a progressive symptom complex of adult life for which there is no curative therapy. Parkinson described it as[1]: "Involuntary tremulous motion, with lessened muscular power, in parts not in action and even when supported; with a propensity to bend the trunk forwards, and to pass from a walking to a running pace: the senses and intellect being uninjured." This syndrome is characterized by the frozen expression of the face, the festinating gait, "pill-rolling" tremor, stooped posture, and increased rigidity of the muscles of the extremities and neck. The last symptom, along with the other debilities, causes a diminution of the speed and range of movement and progressively handicaps the patient. As a consequence, he frequently withdraws from activity and social contacts and becomes increasingly dependent, depressed, and disabled.

The prevention of progressive disability in many patients who have paralysis agitans depends to a great extent on their ability and desire to be active. The muscular rigidity, discouragement, and even depression so characteristic of this illness are not conducive to such activity. Recent emphasis on medical and surgical therapies, which, in themselves, may be only palliative, has obscured the importance and often prevented the use of continuing exercises in the treatment of this disease.

While not of help in preventing the tremor, specific exercises prescribed by the physician to prevent contractures and to increase speed of motion in the extremities, along with correction of posture and training in gait, are important in the management of paralysis agitans. In addition, it is necessary to urge the patient to continue to perform the activities of daily living as well as other tasks requiring use of his muscles to prevent the deleterious effects of immobility.

Therapeutic Exercise

Patients should be instructed by physician or physical therapist under the physician's supervision in a program of simple exercises to be performed at least three times daily. Instruction is given first in exercises to obtain and maintain normal range of motion of all the joints in the extremities in order to prevent contractures. For example, to exercise the shoulder, the patient raises the arm forward and upward over the head and then sideways upward over the head. Also, the patient places the palm of the hand on the back of the neck, then rotates the shoulder and extremity until the back of the hand is placed on the shoulder blade. These movements maintain full range of motion in the shoulder.

For the elbow, the forearm is flexed until the finger tips touch the shoulder, and then the elbow is fully straightened. The remaining joints of the upper extremity, especially fingers, are flexed and extended to the fullest extent. The exercises for the fingers are supplemented by occupational therapy, such as craft

Read before the Section on General Practice at the 105th Annual Meeting of the American Medical Association, Chicago, June 13, 1956.

work, which is valuable for coordination and speed of movement of fingers. The lower extremities are exercised in a similar manner with stress on full range of motion of each joint. It is important for patients to obtain full extension of the hip, and, also, the patient should be instructed to extend the back, when lying prone, by lifting head and shoulders from the position of rest. This exercise strengthens the extensor muscles of the back and neck. These movements are repeated 5 to 10 times, three times a day. The patients are encouraged to practice the movements with increasing speed to aid in reducing the rigidity. Some patients have noted that these simple exercises are helpful in reducing rigidity temporarily, so that some difficult task, such as writing, may be performed more easily.[2]

The relationship of the neck is important in the maintenance of good posture. Limited motion of the neck is common in these patients and has an adverse effect on posture and gait.[3] Active movements of the neck in all directions, especially rotation and extension, are encouraged to maintain range of motion. The patient is trained also to correct his posture by practicing standing as tall as possible with head up, chin in, and chest up. The lower part of the abdomen is held in and up, and the hips are rolled under the body to reduce lumbar curve. To facilitate the correction of posture, the patient is taught to stand with heels, hips, shoulder, and head against a wall. The lower part of the back should be pressed toward the wall to reduce the lumbar curve. The patient should attempt to hold this posture whenever standing or walking. Although most of the patients are in older age groups and senile posture changes are common, every effort is made to have them correct the posture at all times.

Special attention is paid to the gait, because most of the patients have the usual difficulties such as propulsion and a shuffling of their feet, which are intensified by poor posture. They are encouraged to walk with a heel-toe gait, bending their knees so that the shuffle is eliminated. The training should include practice in climbing stairs and also making turns. The lack of associated movements of the upper extremities is obvious, and the patient is urged to swing the arms in the normal manner when walking, although it is often not possible.

In addition to the rigidity and difficulty in initiating active movements, the extensor muscles in the lower extremities may be weak. For example, in addition to trouble in initiating movement, frequently the quadriceps muscles are weak and the patient will have difficulty in getting in and out of chairs or climbing stairs. The power of the muscles can be increased by a program of progressive resistance exercises.[4] The patients are instructed to do these exercises once a day, using sandbags that are hung over the foot for weight. It is important that the amount of weight lifted by extension of the knee be increased progressively, usually every week. The number of contractions is limited to 30 in three series of 10 contractions each, first lifting one-half, then three-fourths, and finally the full or maximal weight in one series of 10 contractions. This same program of strengthening exercises may be used for other groups of weak muscles.

Occasionally the patient with paralysis agitans may have considerable limitation of motion of the shoulders or other joints as a result of lack of use and rigidity. It may be necessary to prescribe heat from a simple lamp followed by sedative massage, and the simple exercises as outlined will have to be more strenuous in order to improve the range of motion of the joint. For the shoulders the active exercises may be supplemented by having the patient use an overhead pulley, with each hand holding an end of the rope. In this manner, one arm assists the other to obtain more abduction. An explanation of the purpose of these exercises is an important part of the instruction, so that the patients will be motivated to continue them indefinitely.

Activities of Daily Living

We believe that the continued performances of the usual common tasks of daily living are of paramount importance in the treatment of patients with paralysis agitans. The frequently progressive inability to perform the usual activities and the tendency of friends and family to take over lead to increasing depression and apathy, which may become so severe as to require psychiatric therapy. As the disease progresses, lack of mobility results in contractures that may render the patient bedfast and the outlook hopeless.

In order to arrest this relentless downhill course to immobility and to help ameliorate the symptoms of rigidity, it is necessary to convince the patient and his relatives that he must return to as many activities of daily living as possible. Those common tasks, which may improve the rigidity or prevent its rapid progression, include such everyday occupations as dressing oneself, gardening, and walking. Improvement of mental attitude may be encouraged by sports, such as golf and games, which aid the patient in socializing and help him avoid excessive rumination about his illness. Of paramount importance are those gainful activities such as maintenance of the home and business, which give the patient a sense of achievement. Even though these activities are poorly performed, the patient must be urged to continue them. His family must be willing to encourage him and allow him to complete these tasks unaided. Emphasis must be placed on the fact that the treatment of this disease is concerned with a constant struggle to keep active and thus is a "full-time" job for the patient. In addition, the patient must understand that his goal must be palliation or the prevention of further progression of the disorder rather than cure. While these activities as well as medical and surgical therapy are not curative, the energetic use of all these modes of therapy, when indicated, will usually retard or halt the progressive disability. In some cases there may even be encouraging improvement.

Concerning these patients Parker[5] stated: "Emphasis should be placed on their retention of intellect and the need of carrying on as they have been doing and for as long as they can. They should go on with their flags flying and their guns firing in a useful existence as long as they are able. Resignation is a fatal step for them."

Summary

The prevention of the progressive disability in many patients with paralysis agitans depends to a great extent on their ability and desire to be active. In addition to specific exercises prescribed by the physician, the patient should be encouraged to continue the activities of daily living in order to prevent the deleterious effects of immobility. While both the medical and surgical treatment of these patients are of importance, their use should not be allowed to obscure the value of continuing exercises in the treatment of this disease.

PHILOSOPHY OF RETIREMENT

Allen O. Whipple, M.D., Princeton, N. J.

• *Retirement from one's life occupation is inevitable, and the problem of making it spiritually, physically, and financially comfortable is more important than ever. Seven questions here stated must be answered, especially questions of location and income. If an individual finds the solution that fits his own situation, it becomes easy to develop former interests into avocations that are absorbing, congenial, constructive, and peaceful.*

The problem of when, where, and how to retire from one's work and occupation has to be faced by everyone if he lives long enough. With increased longevity and life expectancy of the population of the United States nearing the age of 70 years, more people are retiring from their life occupations than ever before. Many more professional and business organizations are retiring their personnel at age 65. The wear and tear of the surgeon's life, in many instances, makes retirement mandatory at 65, if not earlier. So the problem of retiring and how to do it is more important than ever.

The first few weeks of retirement may seem like a much-needed vacation, and, if spent in the congenial surroundings of air, water, and sunshine, they may be a delightful experience. But, after a few weeks of loafing and expensive resort bills, and with no occupation, life begins to pall and the idea of returning home, with no promise of former duties or new avocations, becomes more and more of a nightmare.

For these reasons it becomes imperative to plan and prepare for the sunset of life, if it is to be relatively comfortable spiritually, physically, and financially, as well as pleasant and worthwhile to yourself and your family. Avoid above all else the tragedy of becoming an unoccupied, degenerating vegetable. This has happened to many luckless souls who had not anticipated and planned for retirement, and this may happen to anyone who has no avocation or a sense of humor or the joy of living.

Inasmuch as senescence begins at birth and imperceptible gradations of aging continue through the years, everyone has time to prepare for retirement. We grow older every day, and the only way to avoid old age is to die young, but this has nothing to do with the subject at hand.

Hobbies

Because an interesting occupation, an avocation, is essential to the happiness and success of retirement, it must be discussed first. Borodin, the famous Russian musician and composer, was primarily a physician and professor of chemistry. His hobby was music, and he defined it as "a recreation, a pastime, an avocation, that distracts me from my principal activity as a professor." Avocations or hobbies are of all sorts and kinds. They vary from the sublime to the ridiculous. As long as they serve their purpose of giving one congenial occupation it matters not what they are. Studying the theory of relativity may be at one end of the hobby spectrum, collecting epitaphs from moldy tombstones at the other. A sense of humor is of tremendous advantage, but a man without it can still follow a hobby, though it will probably be uninteresting to others. I once knew a serious philologist and clergyman, utterly without humor. His hobby was proving the doctrine of the Trinity. On one occasion at dinner, with watermelon as the dessert, I saw him carve it so that the seeds appeared in groups of three.

Of course some hobbies are far more agreeable to the family and the neighbors than others. Landscape painting, stamp collecting, cooking, and gardening are less noisy than practicing the bull fiddle or the trombone. One thing is certain. It takes time to develop a worthwhile avocation that can be followed and enjoyed after retiring. One should practice and develop it while he is active in his profession or occupation, so that he can enjoy and appreciate it later. This will make him look forward to retirement instead of dreading it, with the knowledge that he will have more time to follow his hobby, or hobbies, for one should have more than one but not too many. Before retiring one has his weekends, and they comprise almost a third of the year. They can be used, misused, or abused, but they do provide time for developing a hobby, without interfering with such other avocations as golf or poker.

There are hobbies that become more interesting and instructive the longer they are followed. One man I know is a wholesale manufacturer of an essential product. He became interested in Persian rugs and carpets. Because of his lucrative business he was able to collect rare and beautiful specimens and now has one of the finest private collections of Oriental carpets in the world. This collecting took him to the Near and Middle East many times and got him interested

---

Read before the Section on Surgery, General and Abdominal, at the 105th Annual Meeting of the American Medical Association, Chicago, June 12, 1956.

in the geography, history, and cultures of those countries, as well as in the materials and dyes used in the making of the finest rugs. He is now a leading authority in the periods, patterns, and origins of Iranian carpets and gives lectures in the leading museums of the country. He has a great library on the geography, history, and traditions of Persia, ancient and modern. He is indeed well equipped for retirement.

Another man, a well-known physician in the South, had a heart attack at the age of 60. His doctors made his retirement mandatory. He had been interested in ornithology, so he decided to turn his estate into a bird sanctuary and devote his time to the further study of birds and their habits. In a few months he had made the many varieties of birds that populated the sanctuary so accustomed to him that they would feed on the brim of his 10-gallon hat. He had a marvelous lot of interesting stories about his birds and their ways. A lady whom I know is widely traveled. She has an amazing collection of keys of all sizes, shapes, sorts, and materials which she has found in the different countries she has visited. An Arab physician whom I met in Jerusalem has what is said to be the world's largest collection of amulets. He told me that the blue used in making amulets is the universal color among superstitious and illiterate peoples. Blue is supposed to prevent bad luck and fend off the evil eye. Cultural hobbies as a rule do not require physical exercise, so that in addition to one such hobby it is wise to have another that takes one outdoors, such as gardening, golf, or fishing.

Collecting, like chess, is a universal avocation. Too often, however, it is limited to one or two people. This is certainly true of that wonderful game of chess. It is absorbing to the two that play it, but it is not exciting to the rest of he family. So absorbing it is with its endless positions and combinations that for long periods there is no conversation but only concentration, to make sure that one does not make a move that will give the opponent the advantage that will give him the win and you the loss of the game. Certainly there is no other game in which there is no luck, only the make or break of the play entirely up to the two opponents. Chess is a delightful hobby for two congenial souls, but it should not be taken too seriously, as insomnia and worse may follow.

Preparing for Retirement

In preparing for retirement there are a number of questions that have to be answered if it is to be a comfortable and happy one: 1. Do you know where you would like to retire, and have you made any plans for it? 2. Do you know the amount of money you will need for yourself and your family? 3. Have you saved and set aside any funds for this purpose? 4. Have you insurance annuities, matured policies, or negotiable securities? 5. Have you settled your debts? 6. Are you willing to make a budget based upon your future income, and are you willing to follow it? 7. Is your retirement income too large? Your income will probably be considerably smaller than when you were working. Having a large income when you have retired has some definite disadvantages. It means continued responsibility, too many houses, and too much traveling. Thoreau once said "A man is rich in proportion to what he is able to do without." Lincoln said "wealth is simply a superfluity of what we don't need."

These questions are not pleasant, but they must be answered if you are to have peace and tranquility later. So prepare these answers before you have to retire.

Retirement Compensations for Surgeon

Let me now discuss the compensations for the surgeon when he retires. Time is his own, to do with it as he pleases—a rare experience after the busy life and trying years of his practice. No more anxious hours before, during, and after critical operations and difficult times with the distraught members of the patient's family and his solicitous friends, as well as the friends that consider themselves influential. No more dull and interminable committee meetings. There will be time to follow pet hobbies, to read many books on many subjects that he has not had time for in the busy years gone by, time to resume investigative problems previously attempted or contemplated, time to sit quietly and review leisurely the happy incidents and experiences of his surgical career, and time to contemplate with tranquility, and with faith, the sunset and twilight of life.

John Buchan once said, "As we age the mystery of time more and more dominates the mind. Time goes on, and for us mortals, in only one direction." However, this time motion has been disputed. Henry Austin Dobson said, "Time goes, you say? Ah no! Alas, Time stays, we go." Today the superscientists review the cosmos as a time-space continuum and time and space as a constant. To the relativity of time, motion, and space Einstein contributed more than anyone else, but this idea is better understood by the following verse:

There was a young lady so bright
She travelled much faster than light
She went out one day in a relative way
And returned on the previous night.

Speaking of time and occupation, Longfellow years ago had this to say:

Ah, nothing is too late
Till the tired heart shall cease to palpitate
Cato learned Greek at eighty, Sophocles
Wrote his grand Oedipus, and Simonides
Bore off the prise for verse from his compeers
When each had numbered more than four score years, . . .
Chaucer, at Woodstock with the nightingales,
At sixty wrote the Canterbury Tales;
Goethe at Weimar, toiling to the last,
Completed Faust when eighty years were past. . . .
For age is opportunity no less
Than youth itself, though in another dress,
And as the evening twilight fades away
The sky is filled with stars, invisible by day.

Goldsmith said "O blest retirement, friend to life's decline." James Barrie said, "God gave us memory, that we might have Roses in December." Finally Robert Browning, in his "Rabbi Ben Ezra," said: "Grow old along with me! The best is yet to be, The last of life, for which the first was made."

30 N. Stanworth Dr.

EFFECTS OF SULFONYLUREA DRUGS IN HOSPITALIZED DIABETIC PATIENTS

Henry L. Wildberger, M.D.
and
Henry T. Ricketts, M.D., Chicago

• *The antidiabetic effects of carbutamide and tolbutamide were studied in 11 normal and 7 diabetic subjects. Doses of 2 gm. of either drug given by mouth under certain standard conditions produced a lowering of the blood sugar level in 10 of the normal subjects. Case histories of the diabetic subjects here given show that only one had a prompt and completely satisfactory response; another had a delayed but ultimately satisfactory response. The responses of the remaining patients were unsatisfactory, and in two the drugs were entirely ineffective. Mild, transient leukopenia was observed twice. Since five of the diabetic subjects had been selected as suitable candidates for sulfonylurea therapy on the basis of previous reports, it appears that the indications and limitations of these drugs require further study.*

Apparently the first report of depression of the blood sugar level by a drug of the sulfonamide group was made in 1942 by Janbon and his associates,[1] who used 2-sulfanilamido-5-isopropyl-1,3,4-thiadiazole. Stimulated by this work, Loubatières[2] embarked on an intensive investigation of the compound, confirming its depressing effect on the blood sugar level. He showed that in dogs it could produce convulsions and irreversible changes in the nervous system analogous to those seen in prolonged insulin hypoglycemia, but that it was ineffective in the dog in which total pancreatectomy had been done. He suggested that the compound facilitated deposition of glycogen in the liver and adduced evidence pointing to a stimulation of insulin secretion.

In 1946, Chen and associates[3] reported hypoglycemia in normal rabbits given 2-sulfanilamido-5-cyclopropyl-1,3,4-thiadiazole and a paradoxical hyperglycemia in alloxanized animals so treated. The latter finding discouraged clinical trial of this material. Three German papers published simultaneously in 1955[4] described the hypoglycemic activity of an orally administered bacteriostatic agent, carbutamide (1-butyl-3-sulfanilylurea), designated BZ-55, in normal animals and normal human subjects and in diabetic patients. At about the same time, workers at the Hoechst laboratories in Germany reported similar results with a related but nonbacteriostatic compound, tolbutamide (1-butyl-3-*p*-tolylsulfonylurea), designated D-860, U-2043, and Orinase.[5]

The possibility that these substances might be effective in the treatment of diabetes mellitus promptly led to their use in extensive clinical investigations, at first in Europe and later in the United States and Canada. As of September, 1956, a total of 1,035 patients treated with sulfonylurea compounds have been reported in the literature available to us,[6] with favorable results in 60 to 80%. Actually, several times this number have received the drugs. Of the 1,035 patients, however, all but 30 appear to have been studied and evaluated by methods either incompletely described or, in our opinion, inadequate to permit unequivocal conclusions as to the efficacy of the treatment. In some instances, the patients had been hospitalized for tuberculosis or other bacterial diseases, so that amelioration of the diabetes might have been attributed to improvement in the infection. In others, patients with diabetes of short or unstated duration were used; since patients with diabetes often tend to improve when first brought under treatment, even though this be only dietary, it is difficult to be certain that any mitigation noted was the result of drug therapy. In still others, the effectiveness of the sulfonamide agent was judged by the ability of the patient to remain aglycosuric when insulin was withdrawn or dosage reduced. The pitfall here is that many older patients can tolerate the withdrawal of most or all of their injected insulin when they are brought into the hospital and placed on well-regulated diets. Finally, in many cases the period of observation before administration of the drug was too short to ensure that carbohydrate metabolism had reached a stable state against which the effect of treatment with sulfonamides could be properly measured.

Purpose

The present investigation was designed primarily to determine the effect of the sulfonylurea drugs, carbutamide and tolbutamide, on the levels of blood and urine sugar of a variety of diabetic patients under experimental conditions that would approximate the ideal as nearly as possible. A secondary aim, actually accomplished before the first, was to test the effect of these drugs in normal individuals in such a way that prolonged fasting and variations in fluid intake would not influence the results.

Procedure

The normal subjects (the majority of whom were male) were 11 individuals selected from the hospital staff and medical students. Each was subjected to three observations: 1. Prior to the administration of any drug, the blood sugar level was determined after an overnight fast and 200 cc. of milk was given immediately. Every two hours thereafter for eight hours, additional blood specimens were obtained and the same amount of milk was given. Regular meals were not ingested until the end of the experimental day. Ordinary activity was not curtailed. 2. Several days later, the entire procedure was repeated, this time with 2 gm. of carbutamide given as a single dose by mouth just before the first feeding of milk. 3. After at least one week, the same experiment was performed with use of tolbutamide. The fasting blood sugar level was determined again on the day after the administration of drug.

From the Department of Medicine, University of Chicago.

Seven patients, including both young and old adults, with diabetes diverse in duration, severity, and lability were hospitalized primarily for experimental study on a metabolic ward for periods of 2 to 11 weeks. Except for one patient, previously adrenalectomized for metastatic carcinoma, none had complications that might influence diabetes. Twenty-four-hour specimens of urine for quantitative determination of glucose were collected, and capillary blood for glucose was obtained four times daily, with patients in the fasting state and three to four hours after each meal. Diets patterned after the home intake as revealed by diet records, and constant with respect to total calories, carbohydrate, protein, and fat, maintained the patients' weight, with no significant gain or loss.

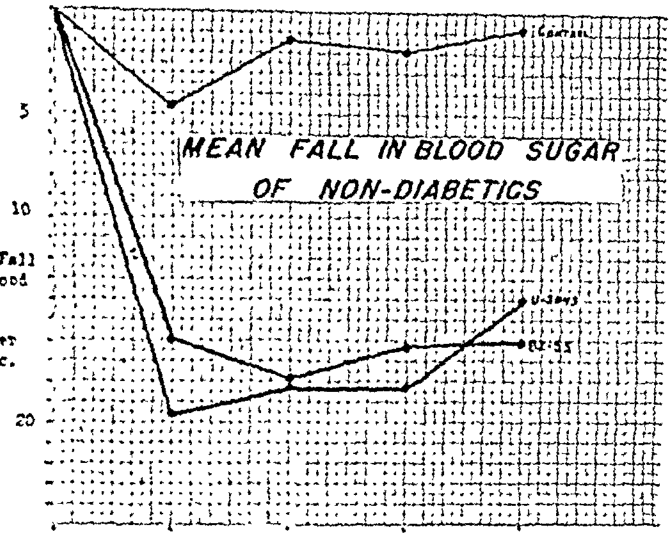

Fig. 1.—Mean fall in blood sugar level in nondiabetic subjects after single dose of either carbutamide or tolbutamide, contrasted with such depression in same individuals when no drug was given; 200 cc. of milk given every two hours during all experiments.

Observation prior to administration of the drug was prolonged until daily blood and urine sugar values seemed well stabilized or on an upward trend. Treatment with either drug was never initiated if blood or urine sugar level was decreasing. In some patients, insulin therapy was not completely discontinued but was reduced to a level that permitted significant hyperglycemia and glycosuria. The dose of insulin was then kept constant through the rest of the period of observation. The sulfonylurea drugs were given in divided doses three times daily except in case 5, in which they were given two times daily. Blood sulfonamide levels in the cases in which they were determined were in the generally accepted therapeutic range of 15 to 20 mg. per 100 cc.

Routine procedures carried out before and during administration of drugs included blood cell counts, complete urinalysis with a search for crystalluria, urea clearance, liver function tests (sulfobromophthalein [Bromsulphalein], cephalin and thymol flocculations, and determination of serum bilirubin value and of alkaline phosphatase value), basal metabolic rate (in some cases radioactive iodine [I^{131}] uptake and clearance), electroencephalograms, urinary 17-ketosteroids, and four-hour corticotropin-eosinophil depression tests.

Results and Report of Cases

Normal Subjects.—Of 11 normal subjects, 10 showed a maximal depression in the blood sugar level greater than 15 mg. per 100 cc. in response to one or both drugs. One failed to respond to either. In the entire group, the mean decrease in blood sugar level between fasting levels and each of the succeeding two-hour levels (e. g., 0 to 2, 0 to 4, 0 to 6, and 0 to 8 hours) was significantly greater when drug plus milk was given than when milk alone was given (fig. 1). Fasting blood sugar values the following morning were generally at predrug levels. Drowsiness and fatigue were noticed by some subjects, usually at a time when the blood sugar value was low. Neither drug was consistently superior to the other in causing hypoglycemia.

Diabetic Subjects.—The results in the seven patients with diabetes are given in the following case reports.

Case 1.—An obese woman aged 36, with diabetes of one year's duration, was observed on the metabolic ward for a total of 63 days. She had taken insulin for one year and, prior to hospitalization, had required approximately 40 units of isophane (NPH) insulin daily. Her weight was 83 kg. (183 lb.) and height, 156 cm. (61.5 in.). The diet contained 2,068 calories, with 202 gm. of carbohydrate, 90 gm. of protein, and 100 gm. of fat. Initially, the mean level of all blood sugar concentrations was approximately 200 mg. per 100 cc., with the patient receiving 20 units of isophane insulin daily. Twenty days were required to discern a mild downward trend in the glycosuria and hyperglycemia. For seven additional days prior to administration of carbutamide, the insulin dosage was decreased to 10 units daily and maintained at this level for the duration of the observations. On this regimen, 24-hour urine specimens showed glycosuria averaging 44 gm., and blood sugar levels were slightly higher than before. On the 28th day of hospitalization, carbutamide therapy was initiated, 3 gm. being given by mouth the first day, 2 gm. the second, and 1.5 gm. per day for several days thereafter. In an effort to achieve a more striking decline in blood sugar level, a daily dose of 3 gm. was resumed. Figure 2 shows the fall in average excretion of sugar from 44 to 12 gm. daily, and an average fall for all blood sugar values of 40 mg. per 100 cc. During a recovery period of 10 days without the drug, the mean blood sugar values climbed to near 200 mg. per 100 cc. and the mean daily excretion of glucose to 34 gm. A further mild fall in blood sugar level averaging 13 mg. per 100 cc. and a decrease in glycosuria from 34 to 10 gm. per 24 hours was accomplished with administration of 3 gm. of tolbutamide daily. Satisfactory control of this patient's diabetes was not obtained on either drug, and she was discharged from the hospital on a weight-reduction diet and regimen of 15 to 20 units of isophane insulin. Subsequent clinic visits revealed minimal glycosuria and nonfasting blood sugar levels under 125 mg. per 100 cc.

Case 2.—An obese woman aged 70, who had had diabetes for 16 years and had used insulin for 10 to 12 years, was observed on the metabolic ward for a total of 57 days. Prior to hospitalization, she had customarily taken 30 to 35 units of protamine zinc insulin daily. Her average weight before and during the period of study was 79.4 kg. (175 lb.), and her height was 157 cm. (62 in.). The diet contained 2,036 calories, with 170 gm. of carbohydrate, 96 gm. of protein, and 108 gm. of fat. Insulin therapy was discontinued after the third hospital day, and the patient was observed for another 12 days before administration of drugs. During the last five days of the control observation period, a

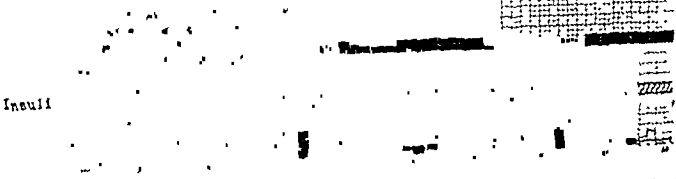

Fig. 2.—Chart of hospital course of patient in case 1. Total period of hospital observation, 63 days. In this and succeeding figures, days are indicated on horizontal axis. Horizontal lines are drawn through the blood sugar graph at levels of 100 and 200 mg. per 100 cc. Medication with sulfonylureas is indicated by solid bars. Insulin dosage is shown by hatched bars. Twenty-four-hour urinary glucose excretion is indicated by the open columns, while mean values for the periods indicated by the arrows are represented by solid columns. See text for details.

slight increase in glycosuria and hyperglycemia was noted. Tolbutamide therapy was started on the 16th day in doses of 3 gm. daily by mouth. On this regimen the average 24-hour excretion of sugar fell from 32 to 15 gm. and the mean blood sugar level from 262 to 237 mg. per 100 cc. A recovery period without the drug led to an average sugar excretion of 43 gm. per 24 hours and an increase in the mean blood sugar level to 286 mg. per 100 cc. Daily administration of 3 gm. of carbutamide was accompanied by a fall in urine sugar from 43 to 26 gm. and a fall in the mean blood sugar value to 251 mg. per 100 cc. Neither drug effected adequate control of this patient's diabetes (fig. 3), and she was sent home on a weight-reduction diet and a regimen of 10 units of isophane insulin daily. Nonfasting blood sugar values determined on return visits to the outpatient department have been 220 and 172 mg. per 100 cc.

Case 3.—An obese man aged 68, with diabetes of three months' duration, was observed in the hospital for 37 days, 23 of which were spent on the metabolic ward. He had never received insulin. His weight was 82.6 kg. (182 lb.) and height, 172.7 cm. (68 in.). The diet contained 1,994 calories, with 150 gm. of carbohydrate, 81 gm. of protein, and 100 gm. of fat. During the first eight days on the metabolic ward while no medicament was given, fasting and postprandial blood sugar values stabilized around a mean of 271 mg. per 100 cc. On the 23rd hospital day (9th on the metabolic ward) 3 gm. of carbutamide was given orally. The dose was reduced to 2 gm. the next day and then to 1.5 gm. for each succeeding day. The mean of all blood sugar values fell slightly to 260 mg. per 100 cc. Average 24-hour glycosuria, however, declined from 50 to 13 gm. The patient has continued to take 1.0 to 1.5 gm. of tolbutamide daily at home, with no glycosuria and nonfasting blood sugar values of 88 and 72 mg. per 100 cc.

Case 4.—A male, aged 24, who had had unstable diabetes for five years and had taken insulin for four years, was observed on the metabolic ward for 54 days. His weight was 68.5 kg. (151 lb.) and height, 172.7 cm. (68 in.). The daily dose of 45 units of isophane insulin used at home was changed to 40 units of protamine zinc insulin daily in the hospital, but excessive glycosuria, often over 100 gm. per day, made it necessary to resume therapy with 45 units of isophane insulin daily. The diet contained 2,384 calories, with 200 gm. of carbohydrate, 99 gm. of protein, and 132 gm. of fat. After 22 days of observation, 3 gm. of carbutamide was given daily by mouth for nine days. The mean of all blood sugar values rose from 199 to 241 mg. per 100 cc. and the 24-hour urine sugar from 34.2 to 58.1 gm. Carbutamide therapy was discontinued, and, without an intervening recovery period, tolbutamide in a dose of 3 gm. daily was given. On this regimen the mean blood sugar level was 206 mg. per 100 cc. and the mean daily sugar excretion was 49.8 gm. Both drugs were totally ineffective in controlling this patient's diabetes, and he was discharged on a regimen of 50 units of isophane insulin daily (fig. 4). Glycosuria continued at home, and a nonfasting blood sugar value was 245 mg. per 100 cc. The patient, maintained for several years and during hospitalization on therapy with phenobarbital and diphenylhydantoin (Dilantin) sodium because of epilepsy, failed to show any change in behavior or electroencephalographic pattern while under therapy with the sulfonylurea preparations.

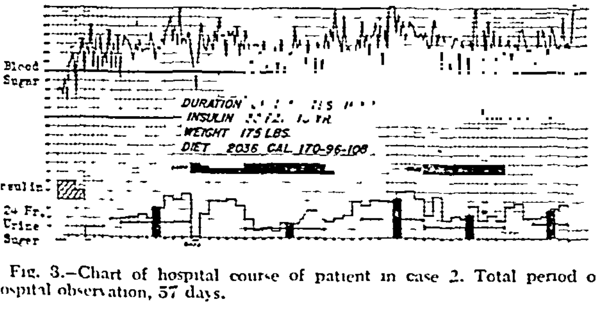

Fig. 3.—Chart of hospital course of patient in case 2. Total period of hospital observation, 57 days.

Case 5.—A woman aged 59, who had had diabetes for one year and who had used 25 units of isophane insulin daily for seven months, was observed on the metabolic ward for 17 days. Her weight was 71.2 kg. (157 lb.) and height 160 cm. (63 in.). This patient had undergone adrenalectomy about one year before the present study because of metastatic carcinoma of the breast. Her diet consisted of 1,592 calories, with 197 gm. of carbohydrate, 75 gm. of protein, and 53 gm. of fat. Prior to and during hospitalization, she was satisfactorily maintained on therapy of 50 mg. of cortisone daily. Insulin therapy was discontinued on admission. Blood sugar values for five days prior to the administration of 1 gm. of carbutamide daily averaged 149 mg. per 100 cc. The mean blood sugar levels on therapy with 1 gm. of carbutamide daily and finally with 2 gm. daily were 156 and 160 mg. per 100 cc. respectively. At no time, either before or during administration of the drug, was glycosuria present. Carbutamide therapy was discontinued when the patient was discharged from the hospital.

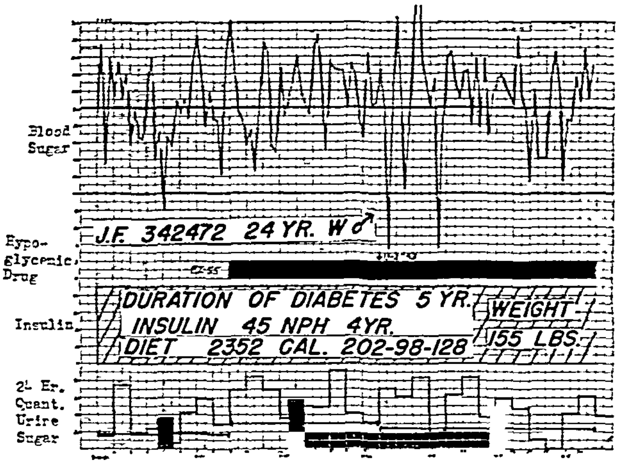

Fig. 4.—Chart of hospital course of patient in case 4. Total period of hospital observation, 54 days.

Case 6.—A moderately obese woman, aged 60, with diabetes of four years' duration and requiring approximately 50 units of isophane insulin daily, was observed in the hospital for 90 days, 76 of which were on the metabolic ward. Her weight was 66.7 kg. (147 lb.) and height 160 cm. (63 in.). Her diet contained 2,045 calories, with 204 gm. of carbohydrate, 98 gm. of protein, and 93 gm. of fat. Withdrawal of insulin for 12 days resulted in blood sugar values of above 240 mg. per 100 cc. at all times, and averaging 365 mg. per 100 cc. Glycosuria averaged 61 gm. daily. Administration of tolbutamide in doses of 3 gm. per day by mouth promptly abolished glycosuria and effected a striking fall in blood sugar to a mean value of 179 mg. per 100 cc. (fig. 5). During the second week of treatment, blood sugar levels fluctuated with rare exceptions between 120 and 140 mg. per 100 cc. Withdrawal of tolbutamide for one week resulted in a steady increase in blood sugar to levels of 280 and 300 mg. per 100 cc. and a mean daily excretion of sugar of 8.5 gm. Treatment with carbutamide (3 gm. per day) caused a fall in blood sugar to levels of 120 to 140 mg. per 100 cc. and again abolished glycosuria. The patient has continued to take 1 gm. of carbutamide daily since discharge from the hospital. No glycosuria has been noted and postprandial blood sugar values have been below 125 mg. per 100 cc.

Case 7.—A slightly obese woman, aged 47, with diabetes of one year's duration who had received insulin (10 units of isophane insulin) for two days only, was observed in the hospital without insulin for 56 days, 42 of which were spent on the metabolic ward. Her weight was 57.6 kg. (127 lb.) and height 150 cm. (59 in.). The diet consisted of 1,829 calories, with 174 gm. of carbohydrate, 83 gm. of protein, and 89 gm. of fat. After 17 days of observation, both blood and urine sugar values seemed stable, averaging 311 mg. per 100 cc. for the former and 50 gm. per day for the latter. Therapy with tolbutamide starting with 3 gm. the first day, 2 gm. the second, and 1.5 gm. daily for the next 17 days caused a slight fall in the mean blood sugar value from 311 to 282 mg. per 100 cc. and a more marked fall in the urinary sugar from 50.4 to 18.2 gm. A recovery period during which the patient received placebos lasted 12 days and resulted in a mean blood sugar value of 287 mg. per 100 cc. and a mean daily urinary sugar of 22.6 gm. Hospitalization could not be further prolonged, and the patient was started on therapy of 1.5 gm. of carbutamide daily at home. She has reported aglycosuria except on rare occasions, and postprandial blood sugar values have been 198 and 172 mg. per 100 cc. No weight loss has been noticed since discharge from the hospital.

Comment

All investigators[7] agree that the sulfonylurea compounds are rarely effective in the growth-onset type of diabetes but that they give good results in a high proportion of middle-aged and elderly obese patients with relatively mild diabetes of not more than a few years' duration. Although the small series of cases here presented is not entitled to statistical consideration, it may nevertheless be significant that striking results were observed in so few of the five patients in whom a favorable response was to be anticipated. Of these, one (case 5) was quite unresponsive to the drugs, two (cases 1 and 7) were only partially responsive so that diabetes could not be controlled with orally given medication alone, one (case 3) showed a partial response in the hospital but a much better one at home, while in only one (case 6) was an excellent therapeutic result obtained. The drugs were neither expected nor found to be effective in two patients, one (case 4) a juvenile diabetic and the other (case 2) an overweight, elderly woman with long duration of both diabetes and treatment with insulin.

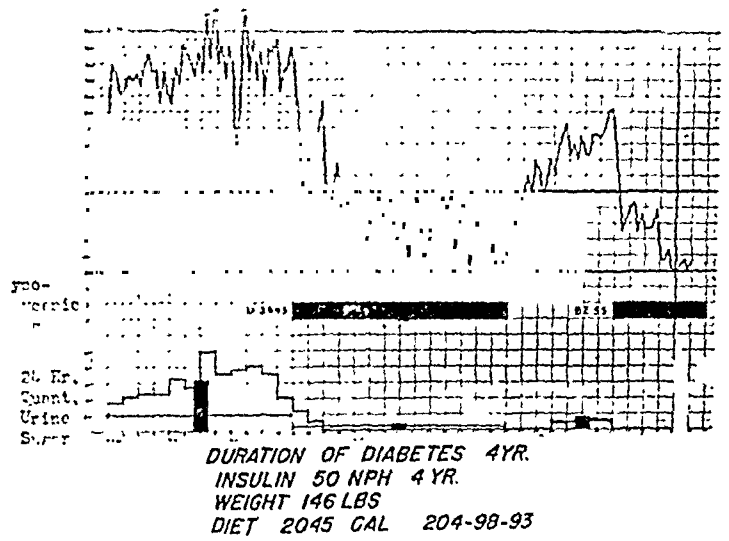

Fig. 5.—Chart of hospital course of patient in case 6. Total period of hospital observation, 90 days.

There may be two reasons for the discrepancy between the degree of success encountered in the present cases and that reported in the literature. The first is a difference in the rigidity of experimental conditions. Attention is called to the long period of observation that is sometimes necessary (e. g., case 1) before the diabetic state can be said to have become stabilized. In such cases a progressive decrease in glycosuria and insulin requirement occurs with no other treatment than exposure to a well-regulated hospital regimen and diet, and the premature administration of a new therapeutic agent can lead to erroneous conclusions. The second is a difference in criteria for "control" of diabetes. We regard good control as the maintenance of two-to-three-hour postprandial blood sugar levels of 150 mg. or less per 100 cc. and freedom from glycosuria, whereas in the majority of reported cases, chiefly from foreign sources, either no specific criteria are given[6] or it is stated that blood sugar values of 250 mg. or less per 100 cc. and glycosuria of less than 30 gm. per day constitute evidence of satisfactory control.[4c]

Contrary to experience with adrenalectomized animals,[7b] which are extremely sensitive to the hypoglycemic action of the sulfonylureas, the adrenalectomized diabetic woman of this series, maintained on 50 mg. of cortisone daily, exhibited no response to the drugs. Neither was she unduly sensitive to insulin. There was no apparent difference in effect on the blood sugar level between carbutamide and tolbutamide.

Side-effects were limited to leukopenia, which occurred in two cases. In one patient (case 2) the white blood cell count prior to treatment was 5,750 per cubic millimeter, with 46% granulocytes. After administration of 26 gm. of tolbutamide in 11 days, these figures were essentially unchanged. Administration of the drug was continued in the same dosage for 5 more days, this being followed by a recovery period of 10 days. At the end of the recovery period, treatment with carbutamide was started, and for the next nine days the patient received a total of 27 gm. Four days after withdrawal of carbutamide the white blood cell count was 3,300 per cubic millimeter, with 29% granulocytes, and two days later these values were 3,900 and 40% respectively. There were no symptoms. In a second patient (case 7) the pretreatment white blood cell count was 12,000 per cubic millimeter. At the end of a 21-day trial of therapy with tolbutamide (total dose 30 gm.), the white blood cell count was 10,000 per cubic millimeter. After a recovery period of 32 days, carbutamide was given on an outpatient basis, the patient receiving 13.5 gm. in 9 days. On the ninth day the white blood cell count was 4,300 per cubic millimeter. The drug was promptly withdrawn, and 22 days later the white blood cell count was 6,900 per cubic millimeter. There were no symptoms.

Neither clinical nor chemical hypoglycemia occurred in the absence of injected insulin, although such reactions have been reported elsewhere.[7b] Crystalluria was looked for but not observed. Treatment with the sulfonylurea compounds caused no change in tests of renal, hepatic, thyroid, adrenal, or cerebral function. Potentiation of barbiturate action, reported to occur in animals with relatively high dosage of carbutamide, was not apparent in the patient receiving anticonvulsive therapy for epilepsy.

The observations here reported throw no light on the mechanism by which the sulfonylurea compounds exert their hypoglycemic activity. Their ability to lower the blood sugar level in the normal subjects of this investigation confirms the experience of others and is in keeping with the hypothesis that the presence of insulin-producing tissue is necessary for this effect. There is experimental evidence pointing both to stimulation of the secretion or release of insulin and to inhibition of the breakdown of liver glycogen,[7b] but other modes of action have not been definitely excluded. It is still uncertain whether the effects on liver and pancreas are accomplished by physiological or innocuous means. Severe, even fatal, hepatitis due to drug intoxication has been reported,[7b] and the possibility of exhausting the already inadequate beta cells by prolonged stimulation, if this is what occurs, must be borne in mind.

Taken together, the rather unimpressive results obtained in this study, the paucity of knowledge concerning the mode of action of these compounds, and the relatively high incidence of side-effects, including some fatalities,[7b] make it probable that the usefulness of the sulfonylureas will be more limited than was originally anticipated and call for continued caution in their clinical application. They may, in selected cases, prove to fill a real need for patients who refuse to take insulin, for those who are allergic to it, and for those whose occupations render the use of insulin dangerous to themselves or others.

Summary

Of five diabetic patients selected on the basis of previous reports as being suitable candidates for treatment with carbutamide and tolbutamide and observed on a metabolic ward under carefully controlled conditions for long periods of time, one exhibited no response to the drugs, two had a partial response but still required insulin for proper control of the blood sugar levels, one had a delayed but ultimately satisfactory response, and one experienced a prompt and completely satisfactory response. The drugs were ineffectual in one patient with juvenile diabetes and in one elderly, obese patient who had taken insulin for many years. They produced significant lowering of the blood sugar level in 10 of 11 normal subjects. Leukopenia developed in two patients who had received first tolbutamide and then carbutamide.

It is suggested that the proportion of patients in whom these preparations can successfully replace insulin will be found to be smaller than previously reported if rigid experimental conditions are maintained and if strict criteria of diabetic control are followed. Use of the drugs will be most clearly justified in patients who will not, cannot, or should not take insulin. Until more is known about their mode of action and their long-term toxic effects, their distribution for general use should be delayed.

CLINICAL NOTES

EFFICACY OF PROMETHAZINE AND PYRATHIAZINE AGAINST ENTEROBIASIS

Harold W. Brown, M.D., Kam-Fai Chan, M.D., New York
and
Harry Yolken, M.D., Paterson, N. J.

Recently Avery[1] reported a 97% cure rate in a group of 100 patients with enterobiasis (pinworm) who were given a single massive dose (125 mg.) of promethazine (Phenergan) hydrochloride. It is obvious that a therapeutic agent that is this effective, if it is nontoxic, offers great promise not only of curing individual patients but also of eliminating Enterobius infection from families, schools, and institutions for children. A previous study by Sadun and others,[2] who treated nine patients with this drug, reported a cure rate of only 44%. In view of Avery's remarkable results and the discrepancy in the results of the two studies, we, in order to verify the results, treated a group of children with promethazine under carefully controlled institutional conditions. A group of children were also treated with pyrathiazine (Pyrrolazote) hydrochloride, a compound closely related to promethazine. To confirm our results, we treated a number of mice infected with Syphacia obvelata, the mouse pinworm, with large doses of these two compounds and compared their therapeutic activity to that of piperazine hydrochloride, which is effective against pinworm in mice and man.[3]

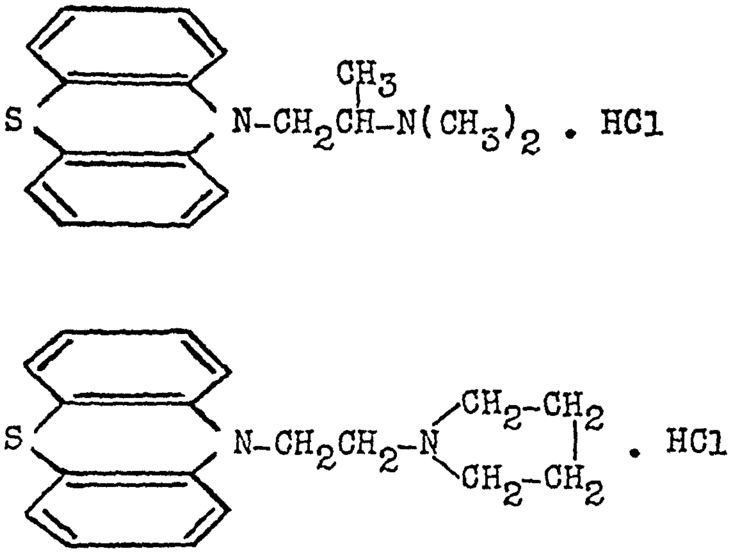
Methods and Results of Treatment

Twenty-five children under 5 years of age, weighing from 27 to 52 lb. (12.2 to 23.6 kg.), were found by the cellophane-tape swab technique to harbor Enterobius vermicularis. They were immediately treated

---

From the College of Physicians and Surgeons, Columbia University (Drs. Brown and Chan) and the North Jersey Training School, Totowa, N. J. (Dr. Yolken).

with either promethazine or pyrathiazine. A single 100-mg. or 125-mg. dose of the drug was administered in the evening before bedtime. No special dietary measures were employed. Seven to nine days after the treatment, cellophane-tape swabs were taken on the children for seven consecutive days. An Enterobius egg on any one of a patient's post-treatment swabs was considered indication of therapeutic failure. These swabs were all taken by us in the morning before the children were bathed. A series of mice experimentally infected with Syphacia obvelata were also given these two drugs, orally, in doses of 100 and 200 mg. per kilogram of body weight on two consecutive days. At autopsy their infection was compared to that of untreated control mice. The studies of Brown, Chan, and Ferrell [1] indicate that there is good correlation in the activity of chemotherapeutic agents against the pinworm of mouse and the pinworm of man.



Structural formulas of promethazine hydrochloride (*above*) and pyrathiazine hydrochloride (*below*).

Five of the 15 children treated with promethazine and 2 of the 10 children treated with pyrathiazine became free of Enterobius eggs after treatment, making the cure rates 33% and 20% respectively (tables 1 and 2). All the children except three became extremely drowsy as a result of therapy and slept heavily all night but were normally active on awakening in the morning. Three of the children treated with promethazine became very excited soon after administration of the drug and continued to be very active for several hours. One became so overactive that he was given a barbiturate in order to induce sleep. The mice given promethazine and pyrathiazine for two days at the rate of 100 and 200 mg. per kilogram of body weight harbored at autopsy approximately the same number of Syphacia as the control untreated mice (table 3). Infected mice given piperazine hydrochloride in these doses lost 65% and 80%, respectively, of their Syphacia.

Comment

Our results indicating that a single large dose of promethazine is relatively ineffective against enterobiasis do not confirm the studies of Avery, who reports a 97% cure rate. He administered a dose of 125 mg. to all his patients, "mainly children 3 to 12 years old," but also some adults. Our group of children were all under 5 years of age. Children weighing under 35 lb. (15.9 kg.) received 100 mg. of the drug, and those over 35 lb. received 125 mg. Although Avery does not present data on the weights of his children, the fact that adults and children up to 12 years of age received 125 mg. of the drug suggests that our therapeutic failures were not due to giving a smaller dose than he gave. Sadun and others,[2] who gave 90-160 mg. of promethazine to a group of nine patients, report a cure rate of 44%, which compares favorably with our 33% cure rate. These authors report that 21% of their untreated patients lost their Enterobius infections during the course of the therapeutic tests; 18% of our untreated control patients lost their infection. The failure of promethazine and pyrathiazine given in large doses to remove the pinworm Syphacia obvelata from mice confirms its ineffectiveness against the pinworm of man.

Piperazine	200 mg./kg./day	6	5	24	115	80

Summary

Promethazine (Phenergan) hydrochloride administered at bedtime in a single dose of 100 or 125 mg. to 15 children, weighing 27 to 52 lb. (12.2 to 23.6 kg.), who were harboring Enterobius vermicularis resulted in a cure of 33% of them. Extreme drowsiness was experienced by 12 of these children, and 3 of them became extremely restless. Only 2 of the 10 children given 100 to 125 mg. of pyrathiazine (Pyrrolazote) hydrochloride lost their infection. These two compounds are likewise ineffective against Syphacia obvelata, the pinworm of mice, even when given in large doses.

OBSERVATIONS ON BODY IMMERSED IN WATER FOR SIX YEARS

Capt. Walter Lentino (MC), U. S. Army

There have been no previous cases documented in the medical literature with gross and microscopic findings on a body immersed in fresh water for six years. The purpose of this article is to describe in detail the findings in such a case. The legal aspects of this case are not considered here. The guilt or innocence of suspects is not properly the concern of medical authorities. A brief review of the background of this case is, however, necessary to indicate the circumstances that led to the discovery of the body and to provide substance for the statement that this body was that of the individual said to have been submerged in water six years before.

Two Italian partisans confessed to complicity in the murder of a U. S. Army officer in December, 1944. They claimed that he had been shot twice through the head with a Beretta pistol, after unsuccessfully being given potassium cyanide in his soup. They stated the body was then weighted in a sack and thrown into the cold waters of Lake Orta, on the borderland between Italy and Switzerland. On June 16, 1950, the waters of Lake Orta were dragged and a body was withdrawn from the location described by the two Italian confessors, together with material and clothes identified as the property of the U. S. Army.

Gross Morphology

The body, when taken from the water, was in a remarkable state of preservation. Eyewitness observers were quoted as saying that it looked like a *fantasmo* (ghost). I arrived to examine the body on June 19 three days after its withdrawal from the water. The body was placed in the cemetery of San Maurizio d'Opaglia, with no special refrigeration, under constant police surveillance. Decomposition was rapidly setting in. The skin and subcutaneous tissues, which were completely intact on first hitting the air, were now rapidly falling away from the body. Because of the delay in arrival of the two professors of legal medicine from the University of Turin, who were to jointly participate in the dissection, the autopsy was postponed an additional day. The grayish-white flesh fell away from the body to the degree that one-fifth of the body became denuded in the 24 hours under my personal observation. On June 20, 1950, with the arrival of Professors Busatti and Romanese of the Institute of Legal Medicine of the University of Turin, the autopsy was jointly begun.

Adipocere Formation

The external soft tissues on close analysis had undergone a peculiar grayish-white change. This process was referred to by the Italian authorities as saponification, a common finding in bodies that have been submerged in water. It is said to represent a change in the fatty acids of the subcutaneous tissues and occurs only after the body has been in water some time.[1] This process, called adipocere formation by American authorities, becomes complete one to one and one-half years after submersion, according to Gonzales and co-workers.[2] Since adipocere formation was complete in this body, it was agreed that the body must have been in the water at least one full year.

Identification of Body

Sex.—The area surrounding the external genitalia had sloughed off by the time the autopsy was performed. Fortunately, there remained intact, attached to the skull, an area of skin about the neck where a short stubbly beard was identified. Final conclusive confirmation of sex came from the identification of a prostate internally and an absence of internal female genitalia.

Race.—The hairs of the scalp were of a dark color and were removed for microscopic analysis by Professors Busatti and Romanese. The sparseness of pigment and the broken centrally placed medullary canal identified the hair as belonging to the body of a white person.[3]

Age.—Examination of the ends of the long bones showed that all the epiphyses were fused. The fusion of the metaphysis of the medial end of the clavicle and the epiphysis definitely placed the body as that of an individual over 25 years of age. Using the method of Krogman,[4] study of the degree of obliteration of the sutures of the skull and the changes in the ridges and grooves of the symphysis pubis placed the age of the body at death as in the middle or early 40's.

Conclusive Identifying Features.—The above-mentioned features all indicate the type of analysis to which unidentified bodies recovered from water are subjected. Specific identification on the above bases would certainly be impossible, yet the body was identified as belonging to a white male in his middle or early

and pyrethiazine for two days at the

[illegible] who had definitely been submerged over one full year at the least. Since the body was specifically identified by the suspects, a study for critically identifying features was undertaken, and three such features were found.

Height: The identified Army officer was a tall man who measured 6 ft. 2 in. (188 cm.) in his bare feet. This precisely matched the height measured on the corpse.

Funnel Chest Deformity: The officer was known to have a pectus excavatum. This was noted upon his medical examinations, and an earlier photograph of him stripped to the waist showed its distinct presence. Autopsy of the body showed a distinct depression of the lower part of the sternum.

Dental Record: A careful analysis of the teeth of the corpse and their fillings was prepared by Prof. Alexander Tardy, an anthropologist working for U. S. Graves Registration. This record agreed closely with that of the officer's private dentist and the record of subsequent fillings done while he was in service.

Cause of Death.—Two bullets were found in the skull of the deceased. The ballistic data indicated that there was close enough correspondence between their riflings and the riflings of the Beretta supplied by the suspects when they confessed. Complete correspondence could not be ascertained because of deformity of the bullets in striking the bony structures. One bullet was lodged in the right occipital lobe after entering the left parietal region. The other was lodged in the base of the skull to the right of the foramen magnum. The second bullet pointed upward, forward, and medial- rd. On the basis of the poor penetration of the bul- he Italian medicolegal experts estimated that the s must have been fired from some distance. This ally indicated that the wounds were not self- icted. Further corroboration came from the location f the wounds. First, the left parietal region is a highly unusual site for suicide by a right-handed man. The bullet that was fired from behind had lodged in such a manner that the murder weapon could not have been held by the deceased. Toxicologic analysis of the stomach contents failed to disclose evidence of any poison.

Microscopic Data

The above information, I feel, definitely identifies this body as that of the Army officer who was dropped into Lake Orta in December, 1944, and was dragged out in June, 1950. Accepting this evidence as adequate for identification of the body, the morphological changes that were found have considerable interest from a medical point of view.

On opening the chest and abdomen, I did not know whether we would find a completely unidentifiable mass of protoplasm or a reasonable facsimile of a human being. As might have been predicted from the gross external examination of the body, the internal organs were in an amazingly intact state of preservation. The heart, lungs, stomach, intestines, liver, spleen, pancreas, adrenals, kidneys, bladder, and prostate were readily and simply identified. Their size, shape, consistency, and location appeared like those of a body freshly examined. Sections of each of these organs were placed in 10% formaldehyde solution (Formalin) for preservation and were then forwarded to the Fourth Medical Laboratory in Heidelberg, Germany, for the preparation of histological sections. After an appropriate period necessary for adequate fixation and staining, the slides were returned to us. The staining technique used was the standard hematoxylin and eosin method. At this point, the most amazing medical feature of the case emerged. Examination of the slides under the microscope showed a complete dissolution of histological structure, so that in no case could any organ be definitely identified.

It is interesting to speculate on what changes occurred in the tissue matrix to permit gross identification of organs as to size, shape, and location, while completely wiping out their histological structure. It would seem reasonable to run experiments with dead tissue immersed in water from different rivers and lakes for different periods of time to determine if a definite pattern exists for the histological disintegration of tissue. It would be of interest to discover whether an orderly pattern of disorganization takes place, which organs are first attacked and to what degree, and whether different natural waters have selective effects. The compilation of such data might well permit the prediction of time of immersion of a body in water in cases where the identification of the corpse is not as easy as in this case.

Summary and Conclusions

Gross and microscopic studies were made of a body immersed in fresh water for six years. There was a peculiar association of complete preservation of the gross structures of the internal organs with complete disintegration of the histological pattern. Experiments should be done with tissue obtained post mortem immersed in water for different periods of time to discover the time and rate at which such histological disintegration takes place and its fashion so that this disintegration may be used as a method for determining length of time of submersion of unidentified bodies.

Geriatric Surgery.—The defeatist attitude toward geriatric su gery common among physicians and the general public unjustified and should be dispelled. The results of surge old age can be gratifying, and necessary surgery should withheld on the score of age alone. Much remains to be the prevention of trauma in old people and in stressing th astrous results of delay in diagnosis of both malignant di and acute abdominal conditions. Early diagnosis and treat are every whit as important as in younger patients. Fo surgeon emphasis must be laid on the prevention of compli tions. Above all shock must be averted by careful supporti measures, by good anesthesia, and by careful, atraumatic sur- gery. Given these, the outlook for the elderly surgical patient i encouraging.—*Jean Limbosch, M.D., Experiences with More Than One Thousand Elderly Surgical Patients, A. M. A. Archives of Surgery*, July, 1956.

COUNCIL ON FOODS AND NUTRITION

Report to the Council

The following paper was presented at the symposium "Some Inorganic Elements in Human Nutrition," in Nashville, Tenn., April 4, 1955. This symposium was sponsored jointly by the Nashville Academy of Medicine, the Vanderbilt University School of Medicine, and the Council on Foods and Nutrition. This report is the fourth of the series, the others of which appeared in THE JOURNAL *April 21, June 9, and Sept. 15, 1956.*

THE METABOLIC ROLE OF ZINC

Bert L. Vallee, M.D., Boston

The metabolic role of zinc has been studied for many years,[1] but it was not until 1940 that Keilin and Mann offered the first concrete explanation of its mode of action.[2] They showed that the enzyme carbonic anhydrase contains 0.33% zinc as a part of its molecule and that zinc is essential to the elimination of carbon dioxide. Thus, zinc and iron have been shown to be components of two proteins, hemoglobin and carbonic anhydrase, pivotal from the point of view of respiratory gas exchange. This work foreshadowed the identification of zinc as a participant in other important enzymatic reactions. Information concerning the physiological and biochemical role of zinc in plant and animal metabolism has been accumulated and reviewed.[3] Therefore, to avoid unnecessary duplication, this paper will cover some of the salient facets of the physiological, biochemical, and clinical implications of zinc metabolism, emphasizing recent observations.

Physiology

The usual human intake of zinc is 10 to 15 mg. per day. The element is excreted mainly through the intestines; the feces contain about 10 mg. and the urine about 0.4 mg. per day.[4] The zinc content of human organs varies from 10 to 200 mcg. per gram of wet weight of tissue. Most organs, including the human pancreas, contain about 20 to 30 mcg. per gram. Contrary to some statements, the pancreas does not have unusually large concentrations of zinc although it has been shown that the islet tissue of fish is rich in the element, containing 100 to 1,000 mcg. per gram of fresh tissue.[5] No significant difference has been detected in the zinc content of the pancreas in normal and diabetic patients. The liver, voluntary muscles, bladder, and bones of man hold 60 to 180 mcg. of zinc per gram of fresh tissue and the normal prostate 859 ± 96 mcg. per gram of dry weight.[6] Outstanding in their content of zinc are the tissues of the eye. From 500 to 1,000 mcg. per gram has been found in the retina and as much as 5,000 mcg. of zinc per gram in the iris of fish and mammals other than man.[7]

The total amount of zinc in the human body has been estimated to be 2 gm. Apparently no tissue stores zinc preferentially. Human whole blood contains about 900 mcg. of zinc per 100 ml.[8] No serum zinc levels probably range from 80 to 170 m per 100 ml.; Vikbladh reports average and norr values of 124 ± 16 mcg. per 100 ml.[9] Normal erythr cytes contain 1.44 mg. of zinc per 100 ml. of pack red blood cells. Three per cent of all zinc in hum blood is found in leukocytes, which contain 0.032 mc of zinc per million cells.[8] Blood zinc concentratio do not exhibit seasonal or diurnal variations, nor d they differ between the sexes. They are normal i diabetics.[9]

The distribution of radioactive zinc (Zn^{65}) wa studied in the mouse and dog.[10] In both animals, th liver contained the largest fraction of the injecte dose of Zn^{65} early in the experiment. The most rapi uptake was observed in the liver, kidney, pancreas and pituitary; least activity was found in erythrocytes brain, skeletal muscle, and skin. Red blood cells and bone were the only tissue components to accumulate zinc gradually. This isotope has been detected in dogs and humans for as long as eight months or a year after its administration.[11] With the injecting of radioactive zinc into a pregnant dog, the passage of the isotope across the placenta into all of seven puppies has been demonstrated. The total stable zinc content of the tissues of these animals was similar to that of adults. The ratio of radioactive zinc to total zinc in three of the animals killed at intervals during the first postnatal week showed a redistribution of the isotope in all organs. There was a decrease in concentration in the extremities and a rise in concentration in the viscera.[11]

Zinc deficiency in animals was studied as early as 1922,[12] but the first successful experiments were reported in 1934 and 1935.[13] Todd, Elvehjem, and Hart found that the growth of rats deficient in zinc was only one-third that of normal ones; the zinc-deficient animals required 52% more ration to gain a gram in weight.[13a] Their fur softened and turned black to gray in six to seven weeks. Administration of adequate amounts of zinc subsequent to the termination of the deprivation experiment caused two animals to return to a normal appearance. The rats considered deficient in zinc received 22 mcg. of zinc per day. The feeding of 30 mcg. of zinc per day produced marked improvement; 40 mcg. of zinc per day completely eliminated manifestations of zinc deficiency. The normal controls received 300 mcg. of zinc per day.

From the Biophysics Research Laboratory of the Department of Medicine, Harvard Medical School, and Peter Bent Brigham Hospital.

Studies of the carbohydrate metabolism in these animals deficient in zinc showed a delayed and irregular glucose tolerance curve, with normal fasting blood sugar levels and normal liver glycogen values. These findings suggested delayed absorption of glucose from the gastrointestinal tract.[11] These rats had a low plasma protein level and a definite reduction of pancreatic amylase and proteolytic activity, which could not be restored to normal by the addition of zinc, in vitro or in vivo. Because similar results had been obtained in magnesium deficiency, however, the change was considered the result of general debility.[15] Zinc had no effect on crystalline pepsin and trypsin in vivo. Although no changes in bone phosphatase were found, intestinal phosphatase activity in rats deficient in zinc was considerably decreased. In all the animals the zinc content of the soft tissues was normal, but that of the bone was lowered.[16]

Hove, Elvehjem, and Hart studied carbonic anhydrase activity in animals deficient in zinc. Although a slight anemia was found, there was no significant lowering of the enzyme activity in erythrocytes.[17] Plasma uric acid levels of the rats deficient in zinc were found to be doubled. Carbohydrate, fat, protein, or nucleoprotein content of the diet did not influence the course of zinc deficiency, and the uric acid blood findings were not reversed until five weeks after zinc had been added to the diet. This increased uric acid content seemed to be caused by increased uric acid formation, rather than by lack of destruction, since uricase activity was completely normal.[18]

Zinc and Hormones.—The crystallization of insulin as a zinc salt by Fisher and Scott led to the belief, now widely held, that zinc is an integral part of the insulin molecule. This belief persists in spite of the fact that nickel, cobalt, and cadmium can be used instead of zinc in the crystallization.[19] Actually, Fisher and Scott never stated that zinc was an integral part of the insulin molecule; they reported that these metals and insulin combined in a constant ratio. For zinc, the percentage in combination was 0.52, for cadmium 0.77, for cobalt 0.44; these percentages were not changed by recrystallization. Moreover, amorphous insulin is as active physiologically as is crystallized insulin, and there is little convincing evidence at present that zinc and insulin must combine in vivo to form an active compound. There is far more zinc in the pancreas than would be necessary for insulin activation, and some of it is now accounted for by carboxypeptidase.[20]

Understanding of the interrelation between zinc and insulin has been complicated further by the finding that 0.02% zinc, added to insulin as the chloride, reduces the immediate activity of the hormone by 40%, though the over-all potency of the hormone is not affected if enough time is allowed for it to act. No such effect is obtained when zinc and insulin are injected separately; precipitation of insulin from a zinc insulin solution with trichloroacetic acid restores its initial properties. Nickel causes the same changes.[21]

The subject of the relationship of zinc to the physiology of the pancreas in general and to that of insulin in particular has been reopened recently, based on the histochemical studies of Okamoto.[22] Employing a nonspecific technique based on the use of diphenylthiocarbazone (dithizone), Okamoto found variable amounts of zinc in the islands of Langerhans. With this agent, Kadota[23] produced diabetes in rats; he presumed that dithizone combined with the zinc of insulin to cause this experimental diabetes. On the basis of similar data, Maske concluded that insulin is physiologically stored as a zinc complex in the islands of Langerhans.[24] Other workers[26] found that the experimentally induced diabetic pancreas contained less zinc[25] and Zn^{65} than did its normal counterpart.[26] McIsaac has employed autoradiography to distinguish between the uptake of Zn^{65} by acinar and islet cell tissue of the pancreas.[27] He found that Zn^{65} concentration of the islet cells remained stable throughout the experimental period, whereas the concentration of acinar tissue, initially high, decreased with redistribution and excretion of Zn^{65}. He estimated that 50% of the injected Zn^{65} is excreted rapidly and 42% enters a "compartment" from which the loss is very slow. Zinc in islet tissue, McIsaac believes, is of the latter moiety. No conclusions were drawn concerning the postulated association of zinc with insulin in vivo.

Weitzel analyzed quantitatively the islet tissue of fish for both insulin and zinc and found them to parallel one another.[5] The zinc content varied from 100 to 1,000 mcg. per gram of fresh islet tissue, depending upon the physiological state of the animal. Much more zinc is present than can be bound to insulin. Histochemical evidence advanced in support of the hypothesis that zinc and insulin are associated in vivo is tenuous at best because the method employed is not specific for zinc. McIsaac, whose data are based on Zn^{65} studies, makes the most persuasive case in favor of a zinc-insulin complex,[27] but he is careful not to extrapolate beyond the evidence presented. The debate on zinc-insulin interaction continues without the achievement of a conclusive settlement.

The relationship between zinc and the activation of hormones needs further clarification, in view of the fact that zinc has been said to influence hormones other than insulin.[28] It has been reported that the addition of zinc to hypophysial gonadotropic extracts augments their effect greatly, as judged by production of estrus and changes in the uterus. Similar effects of copper and zinc on follicle-stimulating hormones and luteinizing hormone have been noted in the rat.[28] On the other hand, the addition of zinc to equine gonadotropin decreases its activity. The physiological significance of these findings is not clear.

Zinc and Porphyrins.—It seems certain that a zinc uroporphyrin exists. Some investigators have found the zinc complex of the Waldenström uroporphyrin to be a constant constituent of the urine and feces in cases of intermittent, acute porphyria.[29] Urinary excretion alone seemed to be the rule in the acute, intermittent cases. In fact, the occurrence of the zinc porphyrin complex is characteristic of this type of porphyrinuria, whereas in the congenial type the porphyrin is usually excreted in a free state.[30] In the latter cases, a zinc uroporphyrin is found in the liver. A zinc coproporphyrin, which has also been described,[30a] has been found in cases of lead poisoning,[31] and its presence in the urine of victims of acute rheumatic fever has been confirmed.[30a]

of 10 to 12 years.[47] Certain intractable types of cyanosis and dyspnea of infants at birth have been attributed to very low carbonic anhydrase activity and may be benefited by transfusion of adult red blood cells. A decrease of 50% in the concentration of zinc in the whole blood of Chinese suffering from protein deficiency, acute and chronic beriberi, and pellagra has been reported. No separate values for erythrocytes and serum were obtained, and no hematological data were given.[48]

Changes in Leukocyte Content.—Marked increases of leukocyte zinc have been seen in patients with anemias refractory to all therapy and accompanied by leukocyte counts below 2,000 per cubic millimeter.[49] The zinc concentration of leukocytes in acute and chronic lymphatic and myelogenous leukemia is decreased to 10% of the normal value. With successful therapy, the zinc concentration returns to normal. Administration of zinc salts intravenously fails to raise the leukocyte zinc concentration or to influence the course of the disease. The phenomenon is apparently independent of the maturity of the cells.[50]

Changes in Urine Content.—The normal zinc content of urine, 0.3 to 0.4 mg. per 24-hour volume, has been found to rise sevenfold to 2.1 mg. per 24-hour volume in patients with albuminuria.[4]

Comment

Disturbances of zinc metabolism have been noted in a variety of conditions; their detection, while supplementary to established diagnostic procedures, does not replace these procedures. A great deal more experience is necessary before studies of zinc can be assigned a decisive diagnostic role. At present, there is no known therapeutic role for zinc in systemic disease.

Because of space limitations, the bibliographic references have been omitted from THE JOURNAL and will appear in the author's reprints.

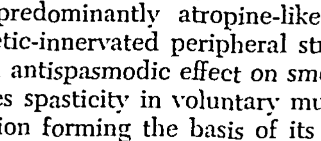
COUNCIL ON PHARMACY AND CHEMISTRY

NEW AND NONOFFICIAL REMEDIES

Monographs and supplemental statements on drugs described here and in subsequent editions of New and Nonofficial Remedies are based on the evaluation of available scientific data and reports of investigations. Applicable commercial names for preparations of evaluated drugs are listed at the end of monographs and parenthetically in the text of supplemental statements; additional commercial names of which the Council is informed will be included with subsequently published supplemental statements and annual editions of New and Nonofficial Remedies.

H. D. KAUTZ, M.D., *Secretary.*

Procyclidine Hydrochloride.—1-Cyclohexyl-1-phenyl-3-pyrrolidino-1-propanol hydrochloride.—The structural formula of procyclidine hydrochloride may be represented as follows:



Actions and Uses.—Procyclidine hydrochloride, a synthetic aminopropanol, is related in chemical structure and pharmacological action to cycrimine hydrochloride and trihexyphenidyl hydrochloride. Thus, the drug exerts predominantly atropine-like actions on parasympathetic-innervated peripheral structures and a pronounced antispasmodic effect on smooth muscle. It also relieves spasticity in voluntary muscle groups, the latter action forming the basis of its clinical use.

Procyclidine hydrochloride is employed for the symptomatic treatment of paralysis agitans (Parkinson's disease). It is as effective for this purpose as the hydrochloride salts of cycrimine and trihexyphenidyl. Thus, the drug is more useful for reducing muscle rigidity in postencephalitic Parkinsonism than in the arteriosclerotic or idiopathic types of the disease. Effect on tremor is variable; in general, tremor is reduced, although in some severely spastic cases this symptom can become exaggerated as rigidity is relieved. For patients with severe tremor and advanced rigidity, the combination of procyclidine with other antispastic drugs may be advisable.

On the basis of laboratory studies and clinical experience thus far, it would appear that the toxicity of procyclidine hydrochloride is not significant. Side-effects are typical of those produced by parasympatholytic drugs and include dryness of the mouth, mydriasis, lightheadedness, and disorientation. Gastric upsets are also produced occasionally. The frequency, duration, and intensity of these side-effects are chiefly a function of dosage and at clinical levels consist usually only of dryness of the mouth. The drug should be administered cautiously to all patients with glaucoma, tachycardia, and urinary retention.

Dosage.—Procyclidine hydrochloride is administered orally. Dosage is variable depending on the age of the patient and the cause of the disease. In general, younger patients and those who have had encephalitis require and tolerate a higher dosage than do older patients and those with arteriosclerotic or idiopathic Parkinsonism. The usual initial dose is 7.5 mg. per day administered in three divided doses after meals. This may then be gradually increased to 15 to 30 mg. per day. Doses as high as 45 to 60 mg. daily have been employed, usually without undue side-effects.

Applicable commercial name: Kemadrin.

Burroughs Wellcome & Company, Inc., cooperated by furnishing scientific data to aid in the evaluation of procyclidine hydrochloride.

Boston, Dr. Marcia S. Hays, bureau of crippled children's service, *California Department of Public Health*, Berkeley, Calif., Dr. Pearce Bailey, National Institute of Neurological Diseases and Blindness, Bethesda, Md., and Dr. George G. Deaver, Institute of Physical Medicine and Rehabilitation, New York University-Bellevue Medical Center, New York, will participate in presentation of "Medical Progress and Prospects." The afternoon session on "Cerebral Palsy Needs and Services in Illinois" will include presentation of "What We Parents Want for Our Cerebral Palsied Children" by a parent; and "What We Cerebral Palsied Adults Need" by a cerebral palsied adult. "Illinois State Programs for the Cerebral Palsied" will be discussed by Dr. William A. Tomlinson, division of services for crippled children, University of Illinois College of Medicine, Chicago; E. C. Cline, Ph.D., Illinois Division of Vocational Rehabilitation, Springfield; Miss Jane Bull, Illinois Commission for Handicapped Children; Willard Couch, Illinois Department of Public Welfare; and Ray Graham, Division of Exceptional Children, Illinois Office of Public Instruction. There will be no registration fee.

MISSOURI

Personal.—Dr. Henry C. Sweany, formerly director of laboratories and research at the Chicago Municipal Tuberculosis Sanitarium and now director of research, pathology, and allied sciences, Missouri State Sanatorium, Mount Vernon, recently received the medal awarded annually by the American College of Chest Physicians for outstanding contributions in chest pathology.—Dr. Noah D. Fabricant, clinical assistant professor of otolaryngology, University of Illinois College of Medicine, Chicago, will speak on "Diagnosis and Treatment of Ear, Nose, and Throat Diseases" in a Symposium on Office Procedures at the Muehlenbach Hotel, Kansas City, Mo., Nov. 11, under the auspices of the Wyandotte chapter of the Kansas Academy of General Practice, the Greater Kansas City chapter of the Missouri Academy of General Practice, and the Lederle Laboratories.

NEW JERSEY

Beling Lecture.—The New Jersey Neuropsychiatric Association announces the 10th annual C. C. Beling Lecture at the Veterans Administration Hospital, East Orange, Nov. 14. "Disorders of Homeostasis in Nervous and Mental Diseases" will be the subject of Dr. Warren S. McCulloch of the Research Laboratory of Electronics, Massachusetts Institute of Technology, Cambridge, Mass.

Albee Memorial Lecture.—The fifth annual Dr. Fred H. Albee Memorial Lecture will be presented at the Kessler Institute for Rehabilitation, Pleasant Valley Way, West Orange, Nov. 10, 2 p. m., by Dr. Francis J. Braceland, medical director of the Institute of Living, Hartford, Conn. His topic will be "The Role of Psychiatry in Rehabilitation." The program will include significant case presentations by members of the institute medical staff. Members of the medical profession and allied rehabilitation, health, and welfare professional personnel are invited to attend.

Meeting of Alumni Association.—The ninth annual meeting of the Alumni Association of the Jersey City Medical Center will be held at the hospital, Nov. 14. A tour of the medical center and the Seton Hall College of Medicine and Dentistry will be conducted in the morning, and a scientific program, including exhibits, symposiums, and case presentations will be given in the afternoon. Dr. Louis A. M. Krause, clinical professor of medicine, University of Maryland School of Medicine, Baltimore, will be the main speaker at the evening dinner.

NEW YORK

Symposiums on Development of Physiological Thought.—The State University of New York College of Medicine at New York City, Brooklyn, will offer a series of symposiums dealing with the historical development of physiological thought in the medical sciences at its new Basic Sciences Building, 450 Clarkson Ave., Brooklyn, during the coming academic year. The first symposium will consist of the following presentations:

Nov. 13, Dependence of Medicine on Basic Scientific Thought, Owsei Temkin, associate professor of the history of medicine, Johns Hopkins University School of Medicine, Baltimore (4:30-5:30 p. m.). Physiology and the Recurrent Problem of Vitalism, Iago Galdston, executive secretary, committee on medical information, New York Academy of Medicine, New York City (8-9 p. m.).

Nov. 14, Structural Basis of Function and Anatomical Reasoning in Physiological Thought, Lloyd G. Stevenson, associate professor of the history of medicine, McGill University Faculty of Medicine, Montreal, Canada (4:30-5:30 p. m.). Development of Ideas Relating the Brain with the Mind, Horace W. Magoun, Ph.D., professor of anatomy, University of California at Los Angeles School of Medicine (8-9 p. m.).

Nov. 15, Development of Knowledge of the Cardiovascular System, Chauncey D. Leake, Ph.D., assistant dean and public information officer, Ohio State University College of Medicine, Columbus, Ohio (4:30-5:30 p. m.).

New York City

Harvey Lecture.—The third Harvey Lecture in the 1956-1957 series will be delivered Nov. 15, 8:30 p. m., at the New York Academy of Medicine, 103rd Street and Fifth Avenue, by Erwin Chargaff, Ph.D., professor of biochemistry, Columbia University College of Physicians and Surgeons, on nucleic acids and nucleoproteins.

Salmon Lectures.—The 24th series of the Thomas William Salmon Lectures will be delivered Nov. 15 by Horace W. Magoun, Ph.D., professor of anatomy, University of California at Los Angeles School of Medicine. Dr. Magoun, visiting scientist at the National Institute of Mental Health in Bethesda, Md., will discuss "The Waking Brain: The Role of the Reticular System in Wakefulness and Behavior." Dr. Magoun's current research is directed to contemporary and historical aspects of the relations of the mind with the brain. The lectures will be given at 4:30 and 8:30 p. m. in Hosack Hall of the New York Academy of Medicine.

School Health Study.—The Welfare and Health Council of New York City has announced the launching of a complementary mental health study as part of its three-year school health survey. According to Dr. Ray E. Trussell, the recently appointed chairman of the survey advisory committee, the survey is being conducted with the co-sponsorship of the New York City Board of Education and Department of Health, with support in part by a $160,000 grant from the U. S. Public Health Service. It will seek to determine the effectiveness of the city school health service in placing children with health problems under care and in improving methods of referral to facilitate proper and timely treatment. Formulation and design of the new mental health program will be undertaken by Dr. Stella Chess, associate clinical professor in psychiatry at Flower and Fifth Avenue Hospitals and coordinating psychiatrist at the Northside Center for Child Development. Dr. Lauretta Bender, research director of the New York State Department of Mental Hygiene, will serve as principal consultant and Dr. William C. Spring Jr. as project director. The school health survey entails a core study of elementary and junior high-school students whose health and academic records will be reviewed. Selected groups of this sample will be given health examinations and checked through interviews with members of the family, teachers, principals, nurses, and others who are concerned with child health. The program is being undertaken in public and parochial schools in the city, including populations of high, medium, and low socioeconomic standing, with due consideration for ethnic, educational, and other characteristics.

NORTH CAROLINA

Grant in Geriatrics.—The psychiatry department of Duke University School of Medicine, Durham, N. C., has been awarded a $211,000 research grant by the National Institute of Mental Health for a five-year continuation of research on the effect of aging on the physiological and psychological functioning of elderly people. Dr. Ewald W. Busse, chairman, psychiatry department, is chief investigator for the project. Working with him will be a research team composed of some 16 faculty members, research workers, and graduate students, who will continue the work initiated in 1950 by Dr. Busse and his associates at the University of Colorado School of Medicine in Denver. The project's primary goal is to provide a better understanding of the changes that take place in normal people as they become older. An annual budget of $44,200 has been set up. Research procedures will include study of social and medical histories, psychiatric evaluation, physical examinatio vatio controlled social situations, and psychologi

OHIO

Traineeships in Cardiovascular Disease.—A cardiovascular disease training program for young physicians has been inaugurated by Frank E. Bunts Educational Institute, teaching unit of the Cleveland Clinic. Two-year traineeships oriented toward research and academic practice are available to physicians who have completed approved internships and at least two years of approved residency in internal medicine or pediatrics. For eight months of the traineeship period the participants will study cardiovascular-renal disease in the research division of the institute. The remaining 16 months will be divided equally between study of general cardiology and pediatric and surgical cardiology in the division of medicine. In each field the trainee will undertake a specific research project. Responsibility for the training in the research division is in the hands of Drs. Irvine H. Page, Arthur C. Corcoran, and Harriet P. Dustan. In the division of medicine the responsibility is shared by Drs. A. Carlton Ernstene, William L. Proudfit, and F. Mason Sones Jr. Information may be obtained from the program coordinator, Dr. Charles L. Leedham, Frank E. Bunts Educational Institute, 2020 E. 93rd St., Cleveland 6.

PENNSYLVANIA

Alumni Association Day.—The Medical Alumni Association of the University of Pittsburgh will hold its sixth annual Scientific Day in the Mellon Institute Auditorium, Pittsburgh, Nov. 16. At 10 a. m. Dr. George Crile Jr., Cleveland, will discuss "Factors Influencing the Dissemination of Cancer" which will be followed by "The Definition of Inoperability of Cancer" by Dr. George T. Pack, New York. Luncheon will be held at Webster Hall. The afternoon session will open at 3 p. m. with "Use and Abuse of Steroids in Therapy" by Dr. William A. Sodeman, Columbia, Mo., and will be followed by the presentation of "The Pathogenesis of Fever" by Dr. W. Barry Wood Jr., Baltimore. Scientific exhibits will be on display from 2 to 5 p. m. A cocktail hour will be held at 5 p. m.

Philadelphia

Psychiatrists Give Award to Dr. Roche.—At the annual meeting of the American Psychiatric Association, Dr. Philip Q. Roche, assistant professor of psychiatry, University of Pennsylvania School of Medicine and University of Pennsylvania Graduate School of Medicine, received the $1,000 Isaac Ray Lectureship award, given annually to a lawyer or psychiatrist for contributing importantly to better understanding between the two professions. Dr. Roche, who was at one time chairman of a joint commission of the Philadelphia County Medical Society and the Philadelphia Bar Association, was largely responsible for the "Pennsylvania Plan for Intramural Training in Penal Psychiatry," which, supported by the Commonwealth Fund, provided fellowships for training physicians in penal psychiatry at Eastern State Penitentiary in Pennsylvania. A founding member of the Pennsylvania Psychiatric Society, Dr. Roche served as its president in 1952-1953.

Cited for Aiding the Handicapped.—Dr. Albert A. Martucci, a past-president of the Philadelphia County Medical Society and during the past 13 years chairman of the commission on physical medicine and rehabilitation of the Medical Society of the State of Pennsylvania, has been cited by President Eisenhower "for outstanding service in promoting equal opportunity in employment for the physically handicapped." He also has received the award given annually to one person in each state by the President's Committee on Employment of the Physically Handicapped. Dr. Martucci is associate professor of physical medicine and rehabilitation, University of Pennsylvania Graduate School of Medicine; associate professor of medicine, Woman's Medical College of Pennsylvania; clinical professor of physical medicine and rehabilitation, Temple University School of Medicine; and chief, department of physical medicine and rehabilitation, Philadelphia General, Episcopal, and Abington (Pa.) Memorial hospitals. He is president of the Pennsylvania Academy of Physical Medicine and Rehabilitation; chairman of the Coordinating Committee for the Handicapped, State of Pennsylvania; and a member of the professional and advisory boards of the United Cerebral Palsy of Pennsylvania and United Cerebral Palsy of Philadelphia and Vicinity.

SOUTH DAKOTA

Lectureships in Medical Sciences.—The South Dakota chapter of the Student American Medical Association will sponsor the first of an annual series of lectureships in medical sciences at the University of South Dakota School of Medical Sciences, Vermillion, Nov. 16. The speaker will be Horace W. Magoun, Ph.D., professor of anatomy, University of California at Los Angeles School of Medicine.

GENERAL

Meeting of Arteriosclerosis Society.—The 10th annual meeting of the American Society for the Study of Arteriosclerosis will be held at the Palmer House, Chicago, Nov. 11-12. The presidential address will be delivered Sunday at 2:30 p. m. by Dr. Arthur C. Corcoran, Cleveland. The guest lecturer at the luncheon Sunday, 12 noon, will be Dr. Donald Mainland, professor of medical statistics, New York University College of Medicine, New York, who will present "Safety in Numbers." In all, 69 papers will be presented during the sessions. A reception for the 10 past-presidents and their ladies will be held Sunday, 6:30-7:30 p. m. (dress, semiformal).

Meeting on Research in Psychiatry.—The Regional Research Conference of the American Psychiatric Association will be held in Philadelphia on Nov. 16-17. The program of the meeting is entitled "Research in Psychiatry with Special Reference to Drug Therapy." The academic address entitled "Drugs in Psychiatric Research" will be given by Dr. Abraham Wikler of the U. S. Public Health Service Hospital, Lexington, Ky. Meetings on new drugs in psychiatry and methodology in psychiatric research will be under the chairmanships of Dr. Jay L. Hoffman and Dr. David M. Rioch from Washington, D. C. Presentations of investigations will be made by the investigators individually and then in the form of panel discussions.

Meeting of College of Preventive Medicine.—The third annual meeting of the American College of Preventive Medicine will be held in Atlantic City, N. J., Nov. 14-15, under the presidency of Dr. Charles F. Sutton, Springfield, Ill. The meeting will open at 8 p. m. Wednesday at the Ritz-Carlton Hotel with "Changing Public Apathy to Public Action in the Prevention of Disease: The Social Science Approach" by Dr. Henry Van Zile Hyde, Washington, D. C. The Thursday morning program at Convention Hall will open with "Heart Disease in Relation to Employment" by Dr. Leonard J. Goldwater, New York, followed by "Preventive Medicine Aspects of Ionizing Radiation" by Col. John R. Hall Jr., Medical Corps, U. S. Army, Washington, D. C., and "Chemotherapy in Tuberculosis: Progress and Promise" by Dr. Rufus T. Payne, Augusta, Ga.

Visual Optics Conference.—The bureau of visual science of the American Optical Company will present the third of a series of conferences on visual optics and refraction for ophthalmologists in Southbridge, Mass., Nov. 12-14. The sessions will include a lecture entitled "Correction of Subnormal Vision" by Dr. Gerald Fonda, New York, and "Indirect Ophthalmoscopy" by Dr. Charles L. Schepens of the Massachusetts Eye and Ear Infirmary, Boston. Subjects to be discussed by staff members of the bureau include "Basic Concepts in Ophthalmic Optics," "Objective Refractive Tests," "Physiological Methods of Determining Multifocal Corrections," "Ophthalmic Lens Characteristics," "The H-R-R- Color Vision Test," "Monoplex Eyes and Implants," and "Clinical Aspects of Aniseikonia." Field trips through the American Optical Company lens and frame plants and the new research center, and demonstrations of recent advances in instrumentation have also been planned. Details may be obtained from the Bureau of Visual Science, American Optical Company, Southbridge, Mass.

Opportunity for Research with Nuclear Reactors.—Applications are now open to college and university faculty members for places in the Oak Ridge Research Participation Program for 1957. This program is designed to disseminate technical information to educational institutions by enabling faculty members to spend usually the three summer months in research in Oak Ridge laboratories. The Oak Ridge salary for the participant is equivalent to his university salary. The research participation program is one of the oldest continuous programs of the Oak Ridge Institute of Nuclear Studies, which operates under direct contract with the U. S. Atomic Energy Commission. Applications for three-month summer appointments in 1957 should be returned to the University Relations Division, Oak Ridge Institute of Nuclear Studies, P. O. Box 117, Oak Ridge, Tenn., by Dec. 15, 1956. Information may also be obtained from the University Relations Division.

The medical division of the institute conducts extensive studies of the internal and external uses of radioisotopes in the diagnosis and treatment of cancer and associated diseases, and studies in radiation physics. In the special training division there are opportunities for research in instrumentation, radioisotope applications, and the occurrence of radioactivity in ores and sea water.

Annual Meeting on Cerebral Palsy.—The 10th annual session of the American Academy for Cerebral Palsy will be held at the Congress Hotel, Chicago, Nov. 17-19, under the presidency of Dr. Margaret H. Jones, Los Angeles, who will deliver an address at 3 p. m. Saturday. Instructional courses will be given each day in addition to the formal program. Papers to be delivered during the sessions include:

Chemopallidectomy in Involuntary Movement Disorders, Irving S. Cooper, New York

A Rating Scale for Evaluation of Language Development in the Preschool Cerebral Palsied Child, Michael D'Asaro, Ph.D., Irvin Lehroff, Ph.D., Ida L. Zimmerman, Ph.D., and Margaret H. Jones, Los Angeles.

Ways in Which Physicians Influence the Attitudes of Parents of Cerebral Palsied Children, Eugene T. McDonald, Ed.D., University Park, Pa., and Forrest G. Moyer, Allentown, Pa

Effect of a Superimposed Respiratory Pattern (Electrolung) on the Speech and Breathing of the Athetoid Child, Frank B. Wilson, Ph.D., and Meyer A. Perlstein, Chicago

The Government's Stake in Cerebral Palsy Research, Glidden L. Brooks, New York.

The National Institute of Neurological Disease and Blindness, Pearce Bailey, Bethesda, Md

Collaborative Project on Clinical Pathological Correlation in Cerebral Palsy, George W. Anderson, Bethesda, Md.

Report of Brain Registry Committee, Meyer A. Perlstein, Chicago

Project Cerebral Palsy, Webb E. Haymaker, Bethesda, Md

A symposium on drug therapy Sunday at 10.15 a. m. will include presentation of "Meprobromate in Cerebral Palsy" by Dr. Harriet E. Gillette, Atlanta, Ga., "Flexin in Cerebral Palsy" by Drs Margaret Watkins and Martha H. Hale, Dallas, Texas, and "Effects of Reserpine on the Learning Capacity of Cerebral Palsied and Other Brain-Damaged Children" by Dr William H. Bradford, Phillip N. Hood, Ph.D., and Joseph Siegel, Ph.D., Dallas, Texas "Behavior and Vulnerability of the Blood-Brain Barrier in the Newborn" by Dr. Angel Pentschew, Washington, D. C., will be the first presentation in a symposium on basic research Sunday, 2 p. m. Dr. Leonard T. Kurland, Bethesda, Md., will discuss "Epidemiological Considerations in Cerebral Palsy" and William F. Windle, Ph.D., will present "Report of Conference on Asphyxia Neonatorum, Brain Damage, and Impairment of Learning." A symposium on orthopedic surgery Monday, 8:30 a. m. will include presentation of "Combined Adductor-Gracilis Tenotomy and Selective Obturator Nerve Resection for the Correction of Adduction Deformities of the Hips" by Dr. Sidney Keats, Newark, N. J., "Adductor Myotomies" by Drs. Henry H Banks and William T. Green, Boston, and "Supracondylar Wedge Asteotomies" by Dr. Frederick G. Day, Edmonton, Alberta, Canada. The buffet supper will be served in the Gold Room, Saturday, 7 p. m.

LATIN AMERICA

Society News.—New officers of the Sociedad de Patologia Clinica y Laboratorio de Guadalajara include Dr. Salvador Urzua, president; Dr. Porfirio Villegas L., secretary; and Dr. Javier Preciado Araiza, treasurer.

Pathologists Meeting.—The Mexican Society of Pathologists will hold a slide seminar in English in Mexico City Nov. 17, to which interested American pathologists are cordially invited. The conductor of the seminar will be Dr. Franklin M. Foote of Memorial Center for Cancer and Allied Diseases, New York. Details will be supplied by Dr. Jose Curiel, Artez 205, Mexico, D. F.

CORRECTION

Teaching in Pathology at University of Chicago.—In the studies of the curriculum in the basic sciences, published in The Journal, Aug. 25, 1956, the information given concerning the hours of pathology taught at the University of Chicago School of Medicine was incorrect. The correct figures are as follows:

Pathology 301: Lectures or discussions including examinations	31 hours
Laboratory	58 hours
	89 hours
Pathology 302: Lectures or discussions, including examinations	38 hours
Laboratory	55 hours
	93 hours
Total	182 hours

The Journal listed 108 hours. Whereas in most of the medical schools special pathology is given in the sophomore year, the University of Chicago gives such training in the junior year, divided over the year. This represents an additional 63 hours of required pathology. Added to this is surgical pathology, also required in the junior year, with 80 hours, and obstetric and gynecologic pathology, an additional 15 hours.

EXAMINATIONS AND LICENSURE

American Board of Anesthesiology. *Part I.* Various locations, July 19 Final date for filing application is Jan. 19 Sec, Dr. Curtiss B Hickcox, 80 Seymour St., Hartford 15, Conn.

American Board of Internal Medicine Subspecialties *Cardiovascular Disease.* Chicago, Nov. 30 Final date for filing application was June 1 *Gastroenterology* Philadelphia, April 5-6. Final date for filing application is March 1.

American Board of Neurological Surgery: Examination given twice annually, in the spring and fall. In order to be eligible a candidate must have his application filed at least six months before the examination time Sec, Dr. Leonard T. Furlow, Washington University School of Medicine St Louis 10

American Board of Obstetrics and Gynecology. *Part I* Various cities of the United States, Canada, and military centers outside the Continental United States, Feb. 1. Candidates must submit case reports to the office of the Secretary within thirty days of being notified of their eligibility to Part I. The cases must be prepared in the manner described in the Bulletin of the board with a duplicate index list. *Part II* Chicago, May 16-25 Request for reexamination in Part II must be received prior to Feb. 1. Sec., Dr. Robert L Faulkner, 2105 Adelbert Road, Cleveland 6, Ohio.

American Board of Ophthalmology. *Oral* St. Louis, Oct. 20-24 *Written* Jan. 21. Final date for filing application was July 1 *Oral* New York, May 23-27, Chicago, Oct. 7-11. Sec, Dr. Merrill J. King, Box 236, Cape Cottage Branch, Portland 9, Maine.

American Board of Orthopaedic Surgery. *Oral Part II.* Chicago, January 1957. Final date for filing application was Aug. 15 Sec., Dr. Sam W. Banks, 116 South Michigan Ave, Chicago 3.

American Board of Pediatrics *Oral Part II* New York City, Oct 12-14, and San Francisco, Dec. 7-9. Sec, Dr. John McK. Mitchell, 6 Cushman Road, Rosemont, Pa

American Board of Physical Medicine and Rehabilitation *Parts I and II* New York City, June 8-9. Final date for filing application is March 1, Sec, Dr. Earl C. Elkins, 200 First St., S W., Rochester, Minn

American Board of Plastic Surgery. Miami, Oct. 17-19 Corres Sec, Mrs. Estelle E Hillerich, 4647 Pershing Ave., St Louis 8

American Board of Preventive Medicine *Oral and Written Public Health* Philadelphia, Nov. 8-10. Sec, Dr. Ernest L Stebbins, 615 N Wolfe St, Baltimore, Md

American Board of Psychiatry and Neurology. *Oral* New York, Dec. 10-11 and New Orleans, Mar 18-19. Final date for filing application is Sept. 10. Sec, Dr. David A. Boyd, Jr., 102-110 Second Ave, S W, Rochester, Minn

American Board of Radiology, Tampa, April 1-6. Final date for filing application is Jan 1. Washington, Sept 23-28. Final date for filing application was June 1. Sec., Dr. B. R Kirklin, Kahler Hotel Bldg, Rochester, Minn

American Board of Surgery. *Part I* Various centers throughout the United States and in certain military centers abroad, Oct 31. *Part II* Rochester, Minn., Oct. 15-16, New Haven, Nov. 19-20, Kansas City, Kan., Dec. 10-11; Los Angeles, Jan. 14-15, San Francisco, Jan 17-18, Houston, Feb. 18-19, Nashville, Mar. 11-12, Boston, April 8-9, and New York, June 10-11.

American Board of Urology. February 1957. Sec, Dr. William Niles Wishard, 1711 N. Capital Ave, Indianapolis 7.

Board of Thoracic Surgery. *Written,* Various centers throughout the country, February 1957, and the closing date for registration is Dec. 1, 1956 Sec., Dr. William M. Tuttle, 1151 Taylor Ave., Detroit 2

GOVERNMENT SERVICES

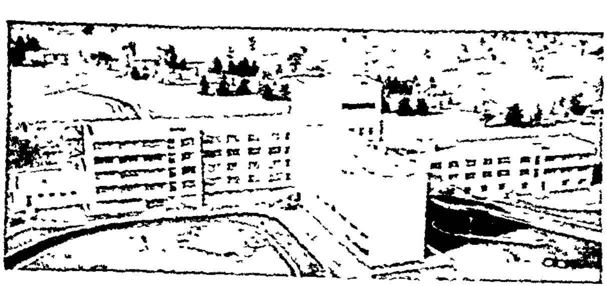
ATOMIC ENERGY COMMISSION

Fellowships in Health Physics Available.—The U. S. Atomic Energy Commission has made available 75 special fellowships for the academic year 1957-1958 in a relatively new field closely related to the atomic-energy program—radiological physics. The Oak Ridge Institute of Nuclear Studies administers the fellowships for the commission. Radiological physics, or health physics, is devoted to the prevention of damage to life or property from radiation and includes such considerations as the disposal of radioactive wastes, biological effects of radiation, the establishment of maximum permissible radiation doses, and the interaction of radiation with matter. The radiological physics program provides for an academic year of formal courses at one of four universities to which fellows may be assigned, followed by a transfer to a corresponding cooperating AEC installation, where fellows train for about three months in applied health physics. The four centers of the program are at the University of Rochester, in cooperation with Brookhaven National Laboratory; the University of Kansas and the University of Washington, in cooperation with the Handord Works; and Vanderbilt University, in cooperation with Oak Ridge National Laboratory. The programs at all four centers will include training in modern physics, radiation biology, radiation instrumentation, industrial hygiene and toxicology, biology, and research.

The basic stipend for AEC fellows is $2,500, with an additional $350 allowed for the spouse and $350 for each dependent child. Fellowship awards include payment of normal tuition and fees required by the university and a travel allowance for the fellow (not for his dependents) from the place of application to his assigned university. Applicants may designate their choice of institutions, although the Oak Ridge Institute of Nuclear Studies cannot guarantee compliance with the choice. Requirements include a bachelor's degree in physics, chemistry, or engineering, acceptability for graduate work at the university, and U. S. citizenship; applicants must be under 35 years of age. Radiological physics fellows should have minors in mathematics, biophysics, or similar fields, although applicants with other qualifications may be considered in special circumstances. Information may be obtained from the Fellowship Office, University Relations Division, Oak Ridge Institute of Nuclear Studies, P. O. Box 117, Oak Ridge, Tenn. Completed applications, supporting letters of reference, and transcripts must reach the institute not later than Feb. 15, 1957, to ensure consideration.

AIR FORCE

New Air Force Hospital at Dayton.—The Air Force dedicated its new 304-bed hospital at the Wright-Patterson Air Force Base in Dayton, Ohio, on Sept. 21. Many physicians and surgeons from throughout the country attended the ceremonies at which the principal speaker was Major Gen. Dan C. Ogle, surgeon general of the Air Force. About 1,000 guests attended. The new hospital cost 6 million dollars and the equipment an additional 1 million dollars. Although rated as a general hospital, it has services not usually found outside specialized institutions. Some of its features are a neuropsychiatric unit, a service for the blind, cold injury treatments, and an arthritis service. It is also the histopathology center for a 19-state area, and it is one of three hospitals in the United States that have a consultation service in aviation medicine. General Ogle pointed out that the Air Force operates more than 200 hospitals throughout the world, 40 of which are 100-bed hospitals or larger, the largest having about 1,000 beds. The Air Force, up to the beginning of this fiscal year, General Ogle said, had obtained approval for the construction of 43 new hospitals within continental United States, 15 of which have been completed and 17 of which are under construction. During this period, it was said, approval had been obtained for the construction of 43 dispensaries, 66 dental clinics, and 10 other miscellaneous medical facilities. A proportionate amount of new construction. General Ogle said, is being accomplished overseas.



New Air Force Hospital, Wright-Patterson Air Force Base, Dayton, Ohio.

ARMY

New Medical Record System.—The new Army health record system becomes effective Jan. 1, 1957; at that time, new regulations on outpatient medical records for nonmilitary personnel also go into effect. Revisions have been made in basic regulations governing individual medical records, clinical records, outpatient medical records, and other recorded data. The outpatient report, one of the three fundamental medical statistical reports, was completely revised as of June, 1956 and new provisions on the morbidity report and the bed and patient reports are now being published. Among other changes now under way are those for the medical follow-up card, the admission and disposition report, and clinical statistics and medical audits.

Under the new system, the Army health record is designed to be a comprehensive medical history of each individual on active duty. It is to be handled so as to be constantly available to medical service personnel, except in periods of actual combat. The different reports will be contained in a folder that accompanies the soldier as a companion to his service record whenever he changes station. While he is on station duty, the folder is in the custody of the medical treatment facility to which he reports for primary medical care. Among other advantages, the new system will minimize the repetition of diagnostic procedures, and might in some instances provide the gain in time needed to save a life. It will reduce correspondence, some of which might be in foreign countries, to obtain information about previous treatment of the soldier. This new record originates when the individual enters the service and has his first physical examination given, his previous medical history outlined, and initial immunization administered. Complete records of all subsequent care are filed in the health folder. Even reports of treatment the individual may receive from civilian or foreign military medical personnel while on active duty are added so the physician treating him may know the whole story.

To provide intensive orientation and to review many details incident to the inauguration of this health record system, the registrars and medical record personnel from Army hospitals throughout the United States and from Europe, Japan, and Puerto Rico assembled at the Walter Reed Medical Center in Washington, D. C., Oct. 8 for a one-week institute conducted by the medical statistics division of the surgeon general's office, where Army and civilian authorities discussed hospital registrar activities and the many changes in the Army's new system of medical records and reports.

Dependents' Medical Care Program.—The surgeon general announces that Major Gen. Paul I. Robinson has been appointed executive director of the new dependents' civilian medical care program. He will head a program to implement a bill enacted by Congress on June 7 providing for medical care in civilian facilities to dependents of active duty military personnel of the "uniformed services." The Army has been designated the executive agent for the "medicare" program. Major General Robinson will be particularly concerned with the arrangement for medical care received from civilian sources for the wives and children of those in the Army, Navy, Air Force, Public Health Service, Coast and Geodetic Survey, and Coast Guard. About 800,000 persons in this category have not received medical care previously because they have not resided near military medical facilities.

NAVY

Transfer to Regular Navy.—The following Naval Reserve medical officers have recently been commissioned in the Medical Corps of the regular Navy: lieutenants R. W. Frazier, E. D. Kaufmann, T. A. Daane, D. L. McCord, David C. Owen, A. K. Rhodes, D. L. Seig, R. I. Sorenson, R. W. Taylor and C. C. Welch.

VETERANS ADMINISTRATION

New Audiology and Speech Correction Chief.—Bernard M. Anderman, Ed.D., chief audiologist of the VA regional office in New York City, has been appointed chief of audiology and speech correction in the VA department of medicine and surgery, Washington, D. C. Dr. Anderman will devote much of his time to the VA program for the reassessment of hearing impairment. Other duties will include programs for hearing aid selection, auditory rehabilitation, and research in audition. He is a member of the American Speech and Hearing Association and formerly was vice-president of the Audiology Study Group of New York City.

Review of Compensation and Pension Claims.—Two years ago the Veterans Administration began a comprehensive review of compensation and pension claims in order to recheck the accuracy of payments made shortly after World War II, when the VA was receiving hundreds of thousands of claims a month and had to train new employees to handle the applications. Eventually, the review will cover 1,713,000 cases of World War II or peacetime veterans under 55 years of age who are receiving compensation for service-connected disabilities. The review is expected to be completed in three or four years. To date, 572,800 such claims have undergone review. In its progress report released Sept. 27, the VA stated that adjustments were found necessary in 30,173 cases or 5.3% of the total claims reviewed thus far.

Following is a comparative breakdown of the adjustments made by the VA:

	Dec 31, 1955	March 31, 1956	June 30, 1956
Increases in monthly payments	2,230	3,263	3,885
Decreases in monthly payments	8,580	10,998	13,290
Terminations of payments	7,989	10,494	12,998
Total	18,799	24,755	30,173

The increases or decreases were made primarily to match the current degree of disability. Of the 12,998 terminations, 10,456 were ended primarily because of improvement in the condition of the patient to such a level that monetary awards are no longer justified, and 2,512 were terminated through severance of service-connection after the VA found "clear and unmistakable error" in associating the disability with the period of service.

The VA said that the 10,456 veterans in the first category have confirmed service-connected disabilities and may be returned to the compensation rolls if those ailments again become disabling.

PUBLIC HEALTH SERVICE

Psychopharmacology Service Center.—The Public Health Service has established a new unit to assist in the development of scientifically sound research programs on tranquilizing and other drugs used in the treatment of mental illness, Surgeon General Leroy E. Burney announced Oct. 16. The new unit is called the Psychopharmacology Service Center in the National Institute of Mental Health in Bethesda, Md. Congress this year appropriated 2 million dollars for an intensive research program to study these drugs. Under the auspices of the National Intitute of Mental Health, the center will be responsible for developing a nationwide research program to stimulate support for basic research and preclinical and early screening and testing of tranquilizing and similar drugs. Dr. Jonathan O. Cole has been appointed psychiatrist in charge of the center. As activities of the center develop, Dr. Burney said, technical assistance and research advisory services will be provided to scientists.

Expanding the Commissioned Reserve.—The U. S. Public Health Service has announced the appointment of 117 physicians, nurses, dentists, sanitary engineers, veterinarians, scientists, therapists, and pharmacists to the inactive reserve of its commissioned officer corps. The service is expanding its inactive reserve by organizing and training medical and health personnel throughout the United States and its territories for duty in times of national emergency. Such emergencies might involve the devastation of cities, extensive illness and death from man-made or naturally occurring disease outbreaks, or the disruption of community life caused by hurricanes, floods, earthquakes, and other natural disasters. These officers will serve in the capacities for which their professional training and experience have fitted them. They will be called out principally to reinforce the staffs of official state and local health agencies and to augment the Public Health Service operating staff.

Studies on Air Pollution.—The Public Health Service has allocated $468,025 to other federal agencies for research in community air-pollution work. The Weather Bureau, Department of Commerce, will continue studies started last year on the dispersal of contaminants in the atmosphere. The National Bureau of Standards will undertake to develop rapid field methods of analysis to determine individual substances in the atmosphere. The U. S. Bureau of Mines will continue its investigation of the causes of inadequate incineration of combustible wastes and the means of improving incineration.

Last year the Library of Congress began to prepare a continuing annotated bibliography on air pollution, including references to the physical, biological, engineering, legal-administrative, and economic aspects of atmospheric pollution. To continue this work during the current fiscal year, the Public Health Service has allocated $17,525 to the library. The Department of Agriculture will assign personnel to the Public Health Service to conduct studies of plants as air-pollution indicators. In addition to the agreements noted above, the surgeon general has announced the award of 12 grants, totaling $318,568, for air-pollution research by nonfederal institutions. Various air-pollution studies are also being conducted within the service's own facilities and through contracts with nongovernmental research groups.

Examination for Microbiologists.—Scientists in the field of microbiology may now take examinations for civil service employment with the U. S. Public Health Service's Communicable Disease Center in Atlanta, Ga., or at center activities throughout the country. This category includes bacteriologists, immunoserologists, mycologists, parasitologists, and virologists. Starting salaries range from $5,440 to $11,610, depending on experience and training and the position to be filled. No written test is required. The Communicable Disease Center is the branch of the Public Health Service that plans, coordinates, and provides assistance to state and local health agencies in the control of communicable diseases.

Scientists in the medical microbiologist positions are concerned with research and developmental and investigative work in the specialized fields of pathogenic micro-organisms. Scientists in the higher grades provide scientific and administrative direction in research programs in the specialized fields, determine projects to be initiated, consult with outside authorities, and conduct important research in the specialized field. Information may be obtained from any post office except in civil service regional headquarters cities, or from the U. S. Civil Service Examiners, Communicable Disease Center, Atlanta, Ga.

FOOD AND DRUG ADMINISTRATION

Joint Study of Adverse Drug Reactions.—Prompt reporting of unusual or adverse reactions to drugs is the objective of a new joint study being carried on by 11 leading hospitals, the Food and Drug Administration announced Oct. 17. The pilot reporting system, sponsored by the administration, has been undertaken to obtain information regarding effects that may appear in some patients when drugs are administered to large numbers of people. This problem has been magnified by the increasing number of potent new drugs. Even the most extensive clinical studies cannot forecast all types of drug reactions that may develop throughout the population. The administration said that hospitals provide an ideal site for observing the effects of drugs and obtaining essential information that is not available from other sources. This joint study is being undertaken in the interest of public health, better patient care, and the safe use of drugs.

DEATHS

Weidman, Frederick De Forest, Philadelphia; born in Bristol, Conn., Oct. 16, 1881; University of Pennsylvania Department of Medicine, Philadelphia, 1908; emeritus professor of research in dermatology and mycology at his alma mater, where he served as assistant demonstrator in pathology and normal histology, instructor in gross morbid anatomy, assistant director of the laboratory of dermatological research, acting head of the department of dermatology and syphilology, and in 1923 became professor of dermatological research; for many years on the faculty of the University of Pennsylvania Graduate School of Medicine, where in 1953 he became emeritus professor of research in dermatology and mycology; professor of pathology at the Woman's Medical College of Pennsylvania from 1914 to 1917; specialist certified by the American Board of Dermatology and Syphilology, of which he was vice-president and for many years a member; past-president and secretary of the American Dermatological Association; past-president of the American Academy of Dermatology and Syphilology, Philadelphia Pathological Society, and the Society for Investigative Dermatology; and associate member of the American Medical Association; member of numerous foreign dermatological societies; assistant and later associate pathologist, Philadelphia Zoological Gardens, from 1910 to 1954; served on the staffs of the Philadelphia General Hospital and the Graduate Hospital of the University of Pennsylvania; from 1946 to 1954 consultant, U. S. Naval Hospital and Valley Forge (Pa.) Hospital; during World War II was consultant in tropical medicine to the Secretary of War; served as associate editor of the *Archives of Dermatology and Syphilology*, and of *Mycopathologia et Mycologia Applicata;* a collaborator in Davis' "Cyclopedia of Medicine" and in Appleton's "Practitioner's Library of Medicine and Surgery"; on the editorial board of the *Journal of Investigative Dermatology*, which dedicated its *Festschrift* number to him in the March, 1952, issue; the Nov. 18, 1950, issue of *Modern Medicine* had a symposium on dermatology dedicated to him; died while vacationing at Bailey Island, Maine, Aug. 30, aged 74, of coronary thrombosis.

Siegel, William ⊕ Albany, N. Y.; born Aug. 9, 1895; University and Bellevue Hospital Medical College, New York City, 1918; specialist certified by the American Board of Preventive Medicine; member of the American Trudeau Society and the American Public Health Association; joined the state health department in 1927 as a clinical physician and in 1930 was promoted to associate director of the division of tuberculosis; in July, 1935, was made director of the division and in 1946, director of the tuberculosis case find bureau; after retirement in April, 1955, remained as consultant in the department's division of tuberculosis control; past vice-president of the State Civil Service Employees Association; resident physician from 1919 to 1922 at the Maryland Tuberculosis Sanatorium in State Sanatorium; died Aug. 30, aged 61, of metastatic melanoma.

Cerniglia, Frank Joseph ⊕ Elmhurst, N. Y.; Long Island College Hospital, Brooklyn, 1928; assistant clinical professor of surgery at the New York Homeopathic Medical College and Flower Hospital, New York City; fellow of the American College of Surgeons and the International College of Surgeons; past-president of the Medical Society of the County of Queens, of which he was a trustee, and the Queensboro Surgical Society; member of the planning committee of the Queensboro Council for Social Welfare and member of the council of the Queensboro Tuberculosis and Health Association; on the staffs of the Queens General Hospital, Creedmoor State Hospital, and the Jamaica Hospital in Jamaica; died Sept. 2, aged 52, of heart disease.

Kerr, LeGrand, Sayville, N. Y.; born in New York City in 1870; Bellevue Hospital Medical College, New York City, 1892; an associate member of the American Medical Association; specialist certified by the American Board of Pediatrics; member of the American Academy of Pediatrics; a founder of the Brooklyn Academy of Pediatrics; served as president of the Medical Association of Greater New York; fellow of the American College of Physicians, of which he was a counselor; on the staffs of the Methodist and Swedish hospitals in Brooklyn, Nassau Hospital in Mineola, and the Rockaway Beach (N. Y.) Hospital; died Aug. 10, aged 85, of cerebral hemorrhage.

Albertson, Horace Allen ⊕ Roanoke, Va.; born in Richmond May 25, 1918; Medical College of Virginia, Richmond, 1943; also a graduate in pharmacy; interned at Johns Hopkins Hospital in Baltimore; formerly a resident at the Jefferson Hospital in Roanoke, where he was later on the staff; served a residency at the Veterans Administration Hospital in Newington, Conn.; specialist certified by the American Board of Surgery; member of the Southeastern Surgical Congress; fellow of the American College of Surgeons; at one time clinical instructor in surgery at Yale University School of Medicine in New Haven, Conn.; veteran of World War II; died Aug. 20, aged 38.

LeBreton, Prescott, St. Petersburg, Fla.; born in Paterson, N. J., Nov. 4, 1872; Columbia University College of Physicians and Surgeons, New York City, 1896; an associate member of the American Medical Association; specialist certified by the American Board of Orthopaedic Surgery; member of the American Orthopaedic Association and the American Academy of Orthopaedic Surgeons; fellow of the American College of Surgeons; on the staffs of the American Legion Hospital for Crippled Children, St. Anthony's Hospital, and the Mound Park Hospital; died in Middletown, N. Y., July 26, aged 83.

Aiken, Marshall Herbert ⊕ Tiffin, Ohio; Western Reserve University School of Medicine, Cleveland, 1934; died Aug. 3, aged 48.

Anderson, William Laurence, DeBary, Fla.; Tufts College Medical School, Boston, 1914; for many years on the board of education of Staten Island, N. Y.; died in Burlington, Vt., Aug. 10, aged 73, of coronary sclerosis.

Avison, Oliver R., St. Petersburg, Fla.; Victoria University Medical Department, Coburg, Ontario, Canada, 1887; a Presbyterian medical missionary in Korea for many years; first president of the Chosen (Korea) Christian College; died Aug. 28, aged 96, of arteriosclerotic heart disease.

Balofsky, Samuel Lawrence ⊕ Detroit; Tulane University School of Medicine, New Orleans, 1932; associate professor of radiology at Wayne University College of Medicine; specialist certified by the American Board of Radiology; on the staffs of the Detroit Memorial Hospital and the City of Detroit Receiving Hospital, where he died Aug. 11, aged 47.

Bendshadler, George Henry, Portland, Ore.; University of Oregon Medical School, Portland, 1924; certified by the National Board of Medical Examiners; member of the American Academy of General Practice; veteran of World War I; died in the Emanuel Hospital Aug. 22, aged 67, of ruptured aorta.

Booker, Lyle Steele ⊕ Waynesboro, Va.; University College of Medicine, Richmond, 1908; instrumental in the founding of the Waynesboro Community Hospital, where he died Aug. 10, aged 72, of arteriosclerosis.

Burke, John Henry, Elmira, N. Y.; University of Buffalo School of Medicine, Buffalo, 1904; an associate member of the American Medical Association; consultant on the staff of St. Joseph's Hospital, where he died Aug. 19, aged 73, of arteriosclerotic heart disease.

Burns, Frederick John, Otisville, Mich., the Hahnemann Medical College and Hospital, Chicago, 1906; died in Flint Aug. 12, aged 80, of cerebral vascular accident.

Bush, William Bert, St. Louis; Barnes Medical College, St. Louis, 1911; also a dentist; died Aug. 17, aged 79.

Cahoon, Grace Wilson, Los Angeles; University of Minnesota College of Medicine and Surgery, Minneapolis, 1897; at one time practiced in Butte, Mont., and was secretary of the Bow County Medical Society; died July 22, aged 84, of coronary thrombosis.

Carlton, Charles E. ⊕ Stoutland, Mo.; Kansas City (Mo.) Medical College, 1901; on the staff of the Louise G. Wallace Hospital in Lebanon; died Aug. 2, aged 79, of cerebral hemorrhage.

⊕ Indicates Member of the American Medical Association.

Conaway, Benjamin Franklin, Mannington, W. Va.; Maryland Medical College, Baltimore, 1908; died Aug. 28, aged 78, of arteriosclerotic heart disease.

Copp, Francis Allen ⊕ *Jacksonville, Fla.*; Tulane University School of Medicine, New Orleans, 1918; veteran of World War I; died Aug. 7, aged 62.

Corper, Franklin Joseph ⊕ *Skokie, Ill.*; Northwestern University Medical School, Chicago, 1917; specialist certified by the American Board of Pediatrics; member of the American Academy of Pediatrics; on the staff of the Evanston (Ill.) Hospital, where he died Aug. 25, aged 64, of carcinoma of the head of the pancreas.

Crumb, Jaynes Mott, South Otselic, N. Y.; University of Vermont College of Medicine, Burlington, 1902; an associate fellow of the American Medical Association; died in Binghamton Aug. 29, aged 78, of pneumonia.

Daves, Vergil C. ⊕ Vienna, Ga.; Atlanta School of Medicine, Atlanta, 1913; served as state senator and as county physician; on the staff of the Dooly Hospital; died in Macon July 12, aged 69, of coronary thrombosis.

Folkman, Nathan ⊕ Brooklyn, N. Y.; Hahnemann Medical College and Hospital of Philadelphia, 1930; president-elect of the Kings County Surgical Society; veteran of World War II; taught anatomy at Long Island College of Medicine; on the staffs of the Cumberland, Prospect Heights, and Swedish hospitals; died in Lenox, Mass., Aug. 8, aged 48, of coronary thrombosis.

Frank, George Washington, Des Moines, Iowa; State University of Iowa College of Medicine, Iowa City, 1898; veteran of World War I; member of Veterans of Foreign Wars; for many years on the staff of the Veteran Administration Hospital, where he died July 30, aged 80, of coronary occlusion.

Gregg, William T. S. ⊕ Cambridge, Mass.; Michigan College of Medicine and Surgery, Detroit, 1892; member of the Michigan State Medical Society and the American Roentgen Ray Society; formerly on the staff of the Calumet and Hecla Hospital in Calumet, Mich.; formerly health officer in Calumet; died July 15, aged 85, of coronary thrombosis.

Hewes, Ara Bird ⊕ Adrian, Mich.; Cleveland Homeopathic Medical College, Cleveland, 1903; past-president and for a term secretary-treasurer of the Lenawee County Medical Society; veteran of the Spanish-American War and World War I; on the staff of the Emma L. Bixby Hospital; died July 30, aged 82, of coronary thrombosis.

Holzberg, Henry Leopold, San Francisco; University of California School of Medicine, San Francisco, 1915; veteran of World War I; died Aug. 6, aged 63, of carcinoma of the thyroid.

Huycke, Austin H. ⊕ Oregon City, Ore.; McGill University Faculty of Medicine, Montreal, Quebec, Canada, 1907; died in St. Vincent's Hospital, Portland, July 17, aged 74.

Hyman, Abraham Harry, Faust, N. Y.; University and Bellevue Hospital Medical College, New York City, 1910; member of the staff of the Mercy General Hospital in Tupper Lake, where he died July 30, aged 72, of heart disease.

Kamman, George Henry ⊕ Seymour, Ind.; Kentucky School of Medicine, Louisville, 1900; for many years city health officer; secretary of the board of health; on the staff of the Jackson County Schneck Memorial Hospital; died July 20, aged 86, of coronary occlusion.

Kendall, Clarence Fairbanks ⊕ Biddeford, Maine; Medical School of Maine, Portland, 1901; veteran of World War I; served as state district health officer, commissioner of health for the state health department, and with the U. S. Public Health Service; died Aug. 22, aged 80.

King, Hamilton Theodore, Newport, R. I.; Harvard Medical School, Boston, 1904; veteran of World War I; formerly practiced in Joliet, Ill., where he was on the staffs of the Silver Cross and St. Joseph's hospitals; died July 19, aged 76, of pyelonephritis.

Kirkman, Leroy Gresham ⊕ Springfield, N. J.; Columbia University College of Physicians and Surgeons, New York City, 1900; for many years practiced in Newark, where he was on the staffs of St. Michael's Hospital and the Presbyterian Hospital, where he died Aug. 3, aged 80, of coronary thrombosis.

Kohn, Louis Winfield ⊕ New York City; University of Maryland School of Medicine, Baltimore, 1910; specialist certified by the American Board of Internal Medicine; member of the American College of Gastroenterology and the Endocrine Society; fellow of the American College of Physicians; died Aug. 16, aged 67, of a heart attack.

Kolb, Isaac Newton ⊕ Blanchard, Okla.; St. Louis College of Physicians and Surgeons, St. Louis, 1923; died July 31, aged 74, of coronary heart disease.

Livingstone, Joseph William ⊕ Hudson, Wis.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, Chicago, 1905; past-president of the St. Croix Pierce Counties Medical Society; veteran of World War I; served as health officer; died in St. John's Hospital, St. Paul, Minn., July 25, aged 75, of pulmonary emphysema.

McGavin, Agnes Purcell, Morristown, N. J.; University of Toronto Faculty of Medicine, Toronto, Ontario, Canada, 1920; member of the American Psychiatric Association; director of the mental hygiene clinic at the New Jersey State Hospital at Greystone Park; died in the Morristown Memorial Hospital May 6, aged 62, of cancer.

Markowitz, Benjamin ⊕ Bloomington, Ill.; Loyola University School of Medicine, Chicago, 1922; specialist certified by the American Board of Pathology; fellow of the American College of Physicians; member of the College of American Pathologists and the American Society of Clinical Pathologists; past-president of the Illinois Society of Pathologists; served as health officer of Bloomington; pathologist, Brokaw Hospital in Normal, St. Joseph's and Mennonite hospitals; died Sept. 17, aged 60, of prostatic cancer with metastases.

Mast, Earl Cletus ⊕ Mansfield, Ohio; Columbia University College of Physicians and Surgeons, New York City, 1937; member of the American Society of Anesthesiologists; on the staff of the Mansfield General Hospital; died Aug. 19, aged 51, of coronary thrombosis.

Morgans, Dollie Earle, Nashville, Tenn.; Medizinische Fakultät der Universität, Vienna, Austria, 1933; interned at the Henrotin Hospital in Chicago, where she served a residency; formerly a resident at the Illinois Masonic Hospital in Chicago and the Veterans Administration Hospital in Little Rock, Ark.; during World War II served as a second lieutenant in the WAC; died in Miami, Fla., Aug. 8, aged 49.

Murphy, Michael Joseph, Brooklyn, N. Y.; Tufts College Medical School, Boston, 1926; fellow of the American College of Surgeons; veteran of World War II; member of the Medical Society of the State of New York; on the staffs of the St. Mary's, St. Peter's, and the Kings County hospitals; died Aug. 31, aged 58, of coronary disease.

Nichols, Elijah Emera, Pikesville, Md.; University of Maryland School of Medicine, Baltimore, 1911; an associate member of the American Medical Association; died April 6, aged 70, of hypertensive arteriosclerotic heart disease.

Owens, Russell Wayne, Salt Lake City; University of Pennsylvania School of Medicine, Philadelphia, 1920; member of the Utah State Medical Association and the American Academy of General Practice; veteran of World War I; member of the senior staff, Dr. W. H. Groves Latter-Day Saints Hospital; died Aug. 27, aged 60, of chronic cor pulmonale.

Patterson, Frank ⊕ Tyrone, Pa.; Baltimore Medical College, Baltimore, 1902; formerly medical examiner for the Pennsylvania Railroad in Altoona; served on the staff of the Hollidaysburg (Pa.) State Hospital; member of the American Psychiatric Association; died in the Tyrone hospital July 19, aged 78.

Perkins, Edgar Verne ⊕ Chicago; Chicago College of Medicine and Surgery, Chicago, 1913; on the staff of the Evangelical Hospital, where he died Aug. 28, aged 69, of ruptured peptic ulcer.

Poulton, James Elmer ⊕ Staten Island, N. Y.; Northwestern University Medical School, Chicago, 1936; served as secretary of the Richmond County Medical Society; on the staff of the Staten Island Hospital; separated from the U. S. Public Health Service Jan. 10, 1938; died while on vacation at Lake Louise, Alberta, Canada, Aug. 31, aged 50, of coronary thrombosis.

Punche, Albert Emerson, Detroit; University of Illinois College of Medicine, Chicago, 1914; died in the Veterans Administration Hospital, Dearborn, July 2, aged 81, of intestinal obstruction, cancer of the colon, and cerebral arteriosclerosis.

Reed, F. Grendon, Whallonsburg, N. Y.; New York Homeopathic Medical College and Flower Hospital, New York City, 1915; died in the Hudson River State Hospital, Poughkeepsie, May 3, aged 68, of chronic (Huntington's) chorea, bronchopneumonia, and arteriosclerotic heart disease.

Regar, Daniel S., Akron, Pa.; Medico-Chirurgical College of Philadelphia, 1904; also a graduate in pharmacy; for many years member of the board of health; died July 17, aged 87.

Rhea, Clarance Ward, West Allis, Wis.; St. Louis University School of Medicine, St. Louis, 1918; veteran of World War II; served in the regional office of the Veterans Administration in Kansas City, Mo.; at one time on the staff of the Veterans Administration Hospital in Wood; died Aug. 24, aged 65.

Ross, Samuel Tulloch ⊕ Nashville, Tenn.; Vanderbilt University School of Medicine, Nashville, 1915; fellow of the American College of Surgeons; on the staff of the Nashville General Hospital; died in the Mid-State Baptist Hospital July 23, aged 66, of cerebral hemorrhage.

Schoor, William Frederick ⊕ Hutchinson, Kan.; University Medical College of Kansas City, Mo., 1904; served as county coroner; on the staff of the Grace Hospital, where he died June 22, aged 79.

Sohmer, Alphonse Edward John ⊕ Mankato, Minn.; Long Island College Hospital, Brooklyn, N. Y., 1899; fellow of the American College of Surgeons; past-president of the Southern Minnesota Medical Association; past vice-president of the Minnesota State Medical Association; on the staffs of the Immanuel and St. Joseph's hospitals; died Sept. 4, aged 77.

Steffens, Georgia Wetmore, Evanston, Ill.; the Hahnemann Medical College and Hospital, Chicago, 1918; died in Batavia Sept. 10, aged 73, of cerebral arteriosclerosis.

Stephens, James B., Oxford, Miss. (licensed in Tennessee in 1913); member of the Mississippi State Medical Association; died in Water Valley April 24, aged 68, of status asthmaticus.

Steward, W. Benjamin ⊕ Millbrae, Calif.; University Medical College of Kansas City, Mo., 1908; formerly practiced in Topeka, Kan., where he was on the medical and surgical staff of St. Francis Hospital; served on the staffs of the Hollywood Presbyterian Hospital in Los Angeles and the Physicians and Surgeons Hospital in Glendale, Calif.; died in the Peninsula Hospital Aug. 24, aged 76, of complications following a coronary occlusion suffered last December.

Taylor, Robert Stanley ⊕ Bay City, Mich.; University of Michigan Medical School, Ann Arbor, 1948; veteran of World War II; died in the Mercy Hospital Aug. 2, aged 35, of acute coronary occlusion.

Tedesco, Ignatius, New Orleans; Tulane University of Louisiana School of Medicine, New Orleans, 1913; an associate member of the American Medical Association; on the staff of Hotel Dieu, Sisters' Hospital; died July 24, aged 67, of congestive heart disease.

Thomas, Herbert Alfred ⊕ Lima, Ohio; Western Reserve University Medical Department, Cleveland, 1909; on the staff of the Lima Memorial Hospital; died in the Cleveland (Ohio) Clinic Hospital Aug. 17, aged 76, of cardiac arrest.

Tidyman, Gay F., Joliet, Mont.; Northwestern University Medical School, Chicago, 1900; an associate member of the American Medical Association; veteran of the Spanish-American War; formerly surgeon general of the National Department of the U. S. Spanish-American War Veterans; past-president of the Madison County (Mont.) Medical Society; died in Billings July 10, aged 83, of a heart attack.

Titus, Peter Franklin ⊕ Watertown, Mass.; Middlesex University School of Medicine, Waltham, 1942; interned at the Tampa Municipal Hospital in Tampa, Fla.; formerly a resident at the Doctors Hospital and Bellevue Hospital in New York City; resident physician in the ophthalmology department, George F. Geisinger Memorial Hospital and Foss Clinic in Danville, Pa.; formerly a captain in the U. S. Army Reserve; died July 5, aged 44, of a coronary attack.

Trippett, Lemuel Harrison, Jr. ⊕ Amigo, W. Va.; University of Maryland School of Medicine and College of Physicians and Surgeons, Baltimore, 1918; president of the Wyoming County Medical Society; died Sept. 6, aged 60, of coronary occlusion.

Vandale, Albert Leroy, Pawtucket, R. I.; Tufts College Medical School, Boston, 1926; veteran of World War II; for many years superintendent of health of Pawtucket; on the staffs of the Notre Dame Hospital in Central Falls, Roger Williams General and St. Joseph's hospitals in Providence, and the Memorial Hospital; died July 16, aged 58, of carcinoma of the sigmoid with metastases.

Wallis, Otto ⊕ Chicago; Medizinische Fakultät der Universität, Vienna, Austria, 1926; on the staffs of the Frank Cuneo Memorial Hospital and the Columbus Hospital, where he died Sept. 9, aged 55, of coronary insufficiency.

Washburn, Clayton D. ⊕ Jacksonville, Fla.; University of Pennsylvania Department of Medicine, Philadelphia, 1902; on the staff of St. Luke's Hospital; died July 17, aged 82, of dissecting aortic aneurysm.

Weakley, Bertram M., Indianapolis; Medical College of Ohio, Cincinnati, 1904; died July 15, aged 85.

Wender, Max, New York City; University and Bellevue Hospital Medical College, New York City, 1911; on the staffs of the Mount Sinai and Sydenham hospitals; died Aug. 5, aged 69.

Wick, Hilton Addison, New Bethlehem, Pa.; Jefferson Medical College of Philadelphia, 1917; veteran of World War I; served as school director; died in the Maple Avenue Hospital, Du Bois, June 15, aged 62, of congestive heart disease and lung cancer.

Wolf, Richard S., Rochester, N. Y.; Friedrich-Wilhelms-Universität Medizinische Fakultät, Berlin, Prussia, Germany, 1919; on the staff of the Rochester State Hospital; died in the Rochester General Hospital Aug. 6, aged 65, of coronary occlusion.

Woodard, Albert G., Goldsboro, N. C.; University of North Carolina School of Medicine, Chapel Hill, 1907; member of the Medical Society of the State of North Carolina; past-president of the North Carolina Eye, Ear, Nose and Throat Society; past-president and secretary of the Wayne County Medical Society; died in the State Hospital in Morganton July 20, aged 74.

Wright, John Marion ⊕ Hernando, Miss.; Kentucky University Medical Department, Louisville, 1905; died in Memphis, Tenn., Aug. 23, aged 73, of coronary thrombosis and arteriosclerosis.

Wyatt, Fred Howard ⊕ Denver; General Medical College, Chicago, 1924; member of the Indiana State Medical Association; died July 14, aged 69, of pulmonary embolism.

Zaiser, Harry Edgar, Fullerton, Calif.; St. Louis College of Physicians and Surgeons, St. Louis, 1902; fellow of the American College of Surgeons; an associate member of the American Medical Association; for 31 years superintendent of the Orange County General Hospital in Orange; died Aug. 1, aged 76.

Zaur, Israel Sidney ⊕ Bridgeport, Conn.; Yale University School of Medicine, New Haven, 1932; certified by the National Board of Medical Examiners; specialist certified by the American Board of Internal Medicine; fellow of the American College of Physicians; veteran of World War II; member of the consulting staff at the Bridgeport Hospital, where he was formerly chief of staff and where he died July 18, aged 48.

Zimmermann, Walter Charles Lee, Oakland, Calif.; Wisconsin College of Physicians and Surgeons, Milwaukee, 1898; died July 25, aged 81, of cardiac failure, cardiovascular renal disease, arteriosclerosis, and hypertension.

Zuber, Thomas Luther, West Point, Miss.; Meharry Medical College, Nashville, Tenn., 1913; veteran of World War I; died July 26, aged 68.

Zuckerman, Jerome John ⊕ New Rochelle, N. Y.; Cornell University Medical College, New York City, 1908; on the courtesy staff of the New Rochelle Hospital, where he died July 21, aged 70.

AUSTRIA

The Reticuloendothelial System.—At the meeting of the Society for Internal Medicine in Vienna on May 17, Dr. H. Fleischhacker stated that the reticuloendothelial system represents a group of cells in various organs that have been considered together because of their common capacity for intravital storage of dyes. It is necessary to differentiate between the phagocytosing reticular cells (which can be demonstrated in the bone marrow, lymph nodes, liver, and spleen and which represent highly developed end-cells) and the plasma cells, which have definite secretory functions. They have been made responsible for the formation of normal plasma albumin and particularly for the elaboration of gamma globulins. In the presence of abnormal conditions, they also produce paraproteins, macroglobulins, Bence Jones' albumin, and amyloid. Because autoantibodies are also globulins, the concept seems to be justified that the plasma cells, particularly in the lymph nodes and spleen, also play a part in the production of antibodies. It may be assumed that the antigenolytic products that are formed by the phagocytosing reticular cells stimulate the new formation of plasma cells, which only then form the antibodies and release them to the circulation (genetic theory). The small and large lymphoid reticular cells are hardly prominent in normal bone marrow specimens but take part in all the stronger reactions and also in the proliferation of reticular and plasma cells.

Cortisone and prednisone prevent the production of autoantibodies by the suppression of the histiocytic function of the reticuloendothelial system, and they definitely inhibit the production of antibodies that may have started already, as shown by the reduction of the antibody titers in the blood. After the giving of cortisone, sensitized erythrocytes, leukocytes, and thrombocytes, which are loaded with antibodies, no longer stimulate phagocytosis. They are subjected only to the normal rate of breaking up, and their duration of life approaches standard values. Furthermore, the effects of the antibody load with its cytolytic influence are stopped in a manner not yet fully explained. Thus may be explained the good results observed in patients with acquired hemolytic anemia, in those with granulocytopenia and agranulocytosis caused by antibodies, and in those with thrombopenia. The inhibitory influence of cortisone on the reticuloendothelial system may be demonstrated also in the presence of proliferations of this cellular system.

Dr. C. Steffen stated that one ascribes to cortisone a specific influence on the defensive powers of the body. The influence on the defense against infection is paralleled by its influence on antibodies. This influence may be exerted on the formation of antibodies, on the breaking up of antibodies in the presence of an increased protein metabolism, on liberated substances of reaction, and on antigen-antibody formation. An influence on liberated substances of reaction is not generally considered. E. Lauda stated that it is not fitting to describe the spleen as the organ of antibody formation. The spleen has nothing to do with the production of antibodies, or at least it has not more to do with it than any other organ that harbors reticular cells. The case of reticulosis in a patient who later on showed a good response to cortisone and whose temperature was restored to normal by the administration of cortisone could also have been presented as one of a febrile infection in which defervescence was obtained with cortisone therapy. Defervescence has nothing to do with reticulosis. Defervescence as a result of cortisone therapy can be seen in every patient with typhoid fever, but this has no relation to reticulosis. The same reaction to cortisone may be observed in any patient with febrile infection, and, although defervescence takes its course with the defense powers of the organism and thus also with the reticuloendothelial system, this type of infection has nothing to do with the old concept of reticulosis.

BRAZIL

Prevention of Leprosy.—At a meeting of leprologists held in São Paulo in July, Dr. Luis Batista stated that the results of the prophylactic measures used in 1924 have not been satisfactory because the incidence of leprosy has increased tremendously. The participants at the meeting recommended a change of policy that includes the following points: 1. Reporting should be compulsory but the identity of the patients should be kept secret. 2. Isolation of the patient need not necessarily be in a hospital. 3. Treatment may be given in clinics or by private physicians. Before such a program can be accepted, the public must be educated regarding the true nature of the disease. It was further recommended that greater emphasis be placed on teaching medical students about leprosy, because early recognition and treatment of the disease is essential to the success of treatment with the sulfones. At present, one of the greatest difficulties of the leprosy service is to find well-trained physicians who are interested in becoming leprologists. Careers in this specialty should be made more attractive.

FRANCE

Pulmonary Tissue Grafts.—P. Ganter and co-workers (*Rev. franç. étud. clin. et biol.* 1:277-295, 1956) made 566 intraocular grafts of pulmonary and other tissues, mainly in mice. Such pulmonary tissue passes through a primary stage of degeneration with cellular alteration and sometimes necrosis, lasting four days. The initial changes resolving completely, the grafted lung tissue, from the fifth day and persisting for 5 to 20 days, shows signs of viability either by maintaining morphological characteristics similar to those of the original tissue or by growth of the graft and the differentiation of certain elements, in particular the bronchial cells. From about the 12th day, two reactions, usually associated, constantly occur in the tissue and eventually result in the complete disruption of the pulmonary tissue. The first is nearly always a conjunctival reaction starting at the center of the graft or at the point of contact of the bronchus and subsequently invading the entire graft. A lymphocytic infiltration that may be so intense as to give the graft the appearance of lymphoid tissue is associated with this reaction. The lymphocytes may be derived from the host and represent a defense reaction against the foreign tissue, but, in some instances at least, the lymphocytes come from the graft itself. The conjunctival reaction, earlier and more intense if the grafted tissue is adult, and in any case in the guinea-pig, results within 20 to 45 days in replacement of the graft by a fibrous scar, which disappears at about the second month and can no longer be identified after three months. The above changes seem independent of the presence or absence of any revascularization of the graft.

The presence of the pulmonary tissue graft is the cause of an inflammatory reaction and changes in the cornea of the host. The most important is a wild proliferation of the anterior corneal epithelium into the graft, with the formation of stratified centers such as are seen in cutaneous epitheliomas. These structures may invade the entire graft, either by direct extension or by embolism along vessels or air ducts, but never extend beyond the graft and are reabsorbed at the same time as the latter, at about two months. This stimulation of a proliferative reaction by the pulmonary tissue is invariably seen when it is in contact with the anterior corneal epithelium. Operative trauma or the presence of a foreign body in the anterior chamber can be excluded as the primary factors in the stimulation of the corneal epithelium. It is possible, however, that they augment this reaction. Pulmonary tissue would appear to be the only one to possess this property of stimulation. The phenomenon has never been observed with other tissues (fat, liver, kidney, skin, intestine, or trachea). It is not essential for pulmonary tissue to maintain an active metabolism to stimulate the proliferative reaction. Pulmonary tissue destroyed by prolonged grinding retains this property,

The items in these letters are contributed by regular correspondents in the various foreign countries.

although to a lesser degree. It is not proved that bronchial epithelium alone possesses this property, but parenchymal alveolar tissue, with all bronchial tissue removed, certainly does. The proliferative stimulating action of lung tissue is not restricted to corneal epithelium. Cutaneous epithelium, in contact with pulmonary tissue under the same conditions of an intraocular graft, reacts in the same manner, proliferating and forming stratified centers that invade the pulmonary tissue. It would appear that, within certain limits, pulmonary tissue possesses a general stimulating property.

Parietal Fibroplastic Endocarditis. —A. Gerbaux and co-workers at the May 13 meeting of the French Society of Cardiology reported two cases of parietal fibroplastic endocarditis, which brings the cases reported so far to a total of about 20. Clinically the disease has the aspect of a primary global cardiac insufficiency suggestive of Pick's syndrome but with, in addition, a marked eosinophilia. High temperature and renal infection are frequent. The disease is characterized by the presence of a thick fibrous layer covering the parietal endocardium of one or both ventricles. This kind of fibrosis is generally lined with a flattened mural thrombus. In addition there is an endarteritis, or an arrested, dispersed endarteriolitis. There may be lesions suggestive of periarteritis nodosa. According to the authors, the thickening of the endocardium was not due to a simple reaction of the endocardium but to a deposit of fibrin. There is no doubt about the allergic nature of the disease, but its underlying cause remains obscure. In addition to bacterial antigen and a chemical factor, a parasitic origin, particularly filarial, may be the cause in some patients.

Pains After Mitral Commissurotomy.—At the same meeting B. Coblentz and co-workers reported a series of 170 patients on whom mitral commissurotomy had been performed and who had been followed postoperatively for 20 months to five years. In this series 27 patients complained of thoracic or articular pain, occurring during the first weeks after operation. In 15 patients the pain was accompanied by fever, but the late results of the operation were not affected by this complication. The cause of the pain is not known, but a history of rheumatic attacks, focal infection, prolonged operation, or faulty technique are possible factors. On the other hand, it may be a recurrence of an infective endocarditis. Use of aspirin and hormonotherapy seem to be effective and may be of prophylactic value.

Intestinal Cul-de-Sac Following Lateral Anastomosis.—At the meeting of the Society of Surgery in Lille in February, E. Delannoy reported a series of four patients with intestinal cul-de-sacs following lateral ileoileostomy and ileotransversostomy. In some patients this gives rise to symptoms of mild occlusion with relapse. Ulceration on the surface of the stump may give rise to a fistula or peritonitis and in some patients to macrocytic anemia. The authors advise end-to-end anastomosis whenever possible, but, if lateral anastomosis must be done, it should be as near the proximal stump as possible.

Cancer of the Esophagus.—At the same meeting P. Razemon and co-workers reported a series of 41 patients with cancer of the esophagus, 36 of whom were operated on. The maximum survival time was two and one-half years. In spite of the high mortality the authors concluded that an attempt at resection should be made because, if successful, it relieves the patient's progressive dysphagia and alleviates pain.

Cholecystoduodenal Fistula.—Peycelon and P. Replumaz (*Annales de chirurgie Paris*, vol. 32, 1956) say that, in the operative management of cholecystoduodenal fistulas of biliary origin, cholecystectomy may solve the biliary problem unless there are also lesions in the main biliary duct. On the other hand, it may be difficult to suture the duodenal perforation. The authors stress the limited efficiency of duodenorrhaphy and advocate gastroduodenectomy in the treatment of wide duodenal gaps with such duodenal narrowing as makes possible only an approximating or stenosing suture.

Gastric Reticulum Cell Sarcoma.—Rauber and co-workers in the same issue reported a series of five patients with gastric reticulum cell sarcoma. The diagnosis may be suggested by the intensity of the painful syndrome and occasionally by the size of the tumor, which often renders it easily palpable. Roentgenograms may reveal an extramucosal origin of the tumor. On operation, the gross appearance of the tumor may be atypical, and only through histological study is it possible to make the diagnosis. This too may be difficult, particularly in the case of atypical epitheliomas that simulate reticulum cell sarcoma. In most patients gastric reticulum cell sarcoma is rapidly fatal. The only treatment is wide resection. Postoperative roentgenotherapy is only a relatively effective adjuvant.

Meniscal Lesions of the Knee.—Gandin and co-workers in the same issue stated that opaque arthrography is a simple and reliable method for studying the meniscal changes in the knee that frequently occur in sports and military training. It is a valuable aid to the medicolegal assessment of injuries incurred at work. It should not, however, be used by itself to indicate either operation or the operative technique to be used, and it cannot replace clinical examination, which will indicate the treatment of choice. Radiological examination aims only at facilitating the decision by providing complementary information. It can help by preventing useless arthrotomies; by removing any doubt in questionable cases; by confirming the presence of a lesion diagnosed clinically; by defining its site, nature, and extent; by ascertaining the integrity of a meniscus or detecting its defect; and by preventing by an early operation the sequelae of articular traumas.

INDIA

Sensitivity of Vibrio Comma to Antibiotics.—D. C. Lahiri and co-workers (*Indian Journal of Medical Research*, July, 1956) tested 166 strains of Vibrio comma, isolated from a recent epidemic in Calcutta, for their sensitivity to different antibiotics. The organisms were grown from specimens of feces collected during the acute stage of the disease and tested with crystalline penicillin G, dihydrostreptomycin sulfate, tetracycline hydrochloride, chlortetracycline, and chloramphenicol. Results were read after incubation for 20 to 22 hours at 37 C (98.6 F). In general, for their inhibition the organisms required much higher concentrations of crystalline penicillin G and dihydrostreptomycin than of the other antibiotics. Each of these, however, showed a wide range of concentrations between which the most sensitive and the least sensitive strains showed susceptibility. The concentration of a given antibiotic at which all the strains were completely inhibited was 50 to 100 times that at which only the most sensitive strains were completely inhibited. All the strains isolated during this epidemic belonged to the Inaba type. These organisms, isolated during a short space of time, might have been expected to be uniform so far as their antibiotic sensitivity was concerned, but this was not the case. This suggests great diversity in the sensitivity to antibiotics of strains of V. comma. Such a diversity makes precise treatment of cholera with antibiotics a formidable task.

Effect of Sodium Ions on Local Anesthetics.—Y. K. Sinha (*Indian Journal of Medical Research*, July, 1956) studied the effects of local anesthetics on the rectus abdominis muscle of the frog, rabbit and guinea pig ileums, and preparations of cat tracheas immersed in solutions containing different concentrations of sodium ions. The drugs studied were procaine hydrochloride, cocaine hydrochloride, dibucaine hydrochloride, and acetylcholine chloride. It was found that low concentrations of sodium ions in Ringer's solution enhance the antiacetylcholine action of procaine and cocaine on the striated muscle of the frog. High concentrations exert the opposite effect. Low concentrations of sodium ions in Tyrode's solution also enhance the antiacetylcholine action of procaine on the rabbit, guinea pig, and cat smooth muscle; cocaine and dibucaine, however, exhibit a pronounced potentiating effect on the acetylcholine response. Excess of sodium ions might decrease the hydrolysis of salts of procaine and cocaine, thereby reducing their effects, or these drugs might compete with the sodium ion and thus prevent its entry into the muscle cell membrane.

Nutritional Edema.—P. S. Venkatachalam and co-workers (*Indian Journal of Medical Research*, July, 1956) state that nutritional edema is primarily due to protein deficiency during the they can enter the intima. When deposition has already taken place, heparin, via lipoprotein lipase, may be able to split up the lipoproteins in the plaques themselves. Heparin is indicated also in hyperlipoproteinemia in those without arteriosclerosis.

Swiss Medical Profession.—In the winter 1955-1956 there were 3,119 medical students in Switzerland, of whom 1,275 were foreigners, mostly from America. In the last five years, 253 Swiss students of an average age of 27 years have qualified as physicians. There are 7,368 licensed physicians in Switzerland (about 2,322 of whom are specialists) and about 4,500,000 inhabitants. In addition, there are 2,232 assistant physicians in hospitals. Of the 7,368 licensed physicians, 902 are women. Every year about 170 physicians start in private practice, and, of these, 60% are specialists. The average age of physicians at death in Switzerland increased from 64 years in 1945 to 68 years in 1955.

UNITED KINGDOM

Medical Education.—The educational number of the *British Medical Journal* (Sept. 1, 1956) has an annotation comparing American and British medical education. It concludes with the statement that all over the world there is a deep dissatisfaction with the content and methods of medical education. This is expressed not only by the graduates in medicine but progressively and more insistently by the teachers themselves. According to Dr. Morgan Jones, tinkering with the curriculum, patching it here, adding to it there, and scarcely ever removing the useless parts, will no longer suffice. The general medical council is criticized for being too rigid and detailed in its recommendations, which have come almost to have the force of regulations. Its present policy tends to frustrate experiment and perpetuate outmoded methods of teaching. The council will no doubt take heed of these criticisms and consider the many remedies that have been suggested by men of experience and wisdom. Those who from different standpoints and in different countries have thought hard and long about medical education all agree that it must be conducted in universities, not in technical schools.

Prevention of Tetanus.—The *British Medical Journal* of Aug. 11 in an editorial says that during World War I the introduction of routine passive immunization for all wounded reduced the incidence of tetanus in a few months from about 8 to 1 per 1,000, later this figure was lowered still further. In World War II active immunization by toxoid was carried out on a large scale in the Allied armies, and the results were remarkably successful. This success is shown in a recent report of the Army pathology advisory committee, which indicates that a person is to be considered actively immunized for a period of six months if he has received two injections of toxoid, the second not less than 6 or more than 12 weeks after the first, and that he is to be considered immunized for a period of five years if he has received three injections of toxoid, the third not less than 6 or more than 12 months after the second. A dose of toxoid should be given immediately to all wounded men regardless of whether they are actively immunized. In addition, tetanus antitoxin should be given as soon as possible after wounding to any nonimmunized person; its administration should be repeated at seven-day intervals, at the medical officer's discretion. In peacetime, a booster dose of toxoid for all actively immunized persons is recommended every five years. The application of these rules would practically stamp out tetanus.

At present, active immunization of the civilian population in Britain is casual. Apart from the difficulty of deciding whether a particular wound requires an antitoxin, there is the danger of reactions to horse serum after passive immunization. An inquiry at 37 hospitals revealed that 31 were still using the intradermal test of skin sensitivity as a guide to general or constitutional sensitivity, although this test is recognized to be unsatisfactory. Dr. N. H. Moynihan investigated the practical outcome of this test on a series of 8,900 patients and found that, of these, 1,027 (11.5%), who were judged to need prophylaxis were not given it because the intradermal test was positive. A further 293 did not receive prophylactic antitoxin for other reasons: 140 because they had had a previous injection within a period of 3 weeks to 18 months and were erroneously deemed to be sufficiently protected; 70 because of a personal or familial history of allergy, 24 because a general reaction followed a sensitivity test dose; and 59 because they refused.

It is now known that effective protection following a dose of 1,500 units lasts for less than four weeks and may be as short as three days in patients who have had a previous injection. When it was found that these so-called positive skin tests formed such a high proportion of the total, Moynihan carried out two further investigations, using isotonic sodium chloride solution as a control against the test dose of antitoxic serum in one series of 100 patients and tap water in another. The isotonic sodium chloride solution and the tap water produced a reaction similar to that with antitoxin in 47% and 28% of the patients respectively. All 200 patients were subsequently given the full dose of prophylactic antitoxin, and only 4.5% developed serum sickness and 5.5% a localized reaction at the site of injection. The method of intradermal testing for sensitivity to horse serum, which is at present used in many hospitals, is unreliable and should be replaced by the trial dose method. This consists in preliminary subcutaneous injections of a small dose of serum with a view to testing the patient's general reaction before giving a larger dose. Moynihan also draws attention to the fact that previous injection of a soluble antigen leads to a much faster removal from the circulating blood of a second or subsequent injection and consequently curtails the prophylactic effect. He concludes that once a person has received an injection of any horse serum antitoxin, regardless of the disease for which it may have been given, that person should be promptly immunized against diphtheria and tetanus with the appropriate toxoid. This recommendation was not carried out in 36 of the 37 hospitals visited.

Salary Freeze.—The effect of the efforts of the government to halt the inflationary spiral is shown in the comments of a group of general practitioners in Southport, Lancashire. The government has refused even to consider the grounds for an increase in the capitation rate. At a special meeting in August, the practitioners resolved (1) that the action of the government in declining to consider their request for increased remuneration was deplorable, (2) to continue its efforts to obtain remuneration adjusted to current living costs, (3) that if after three months the government had not accepted their recommendation, mass resignation from the National Health Service should be called for, and (4) that, in order that this situation should never arise again, an annual assessment and adjustment of remuneration should be made.

Rockefeller Foundation Grants.—The Rockefeller Foundation has recently announced the following grants to support research work in Britain and the Commonwealth. A grant of $47,600 has been made to the London School of Hygiene and Tropical Medicine for research on the biological value of proteins in tropical foodstuffs. The object of this research is to make it easier to attack the problem of protein malnutrition in tropical countries. The University of Cambridge is to receive a grant of $42,000 to inaugurate a research program in animal psychology. The Walter and Eliza Hall Institute of Medical Research in Melbourne, Australia, where basic research is being done on the nature of viruses, has received financial support from the Rockefeller Foundation since 1934, and the latest grant of $60,000 is to cover an eight-year period. A grant of $10,000 is being made to the Florence Nightingale International Foundation in London toward the expenses of a conference on the planning of nursing studies.

Eyes Offered to Save Sight.—Miss Pat Hornsby-Smith, parliamentary secretary for the Ministry of Health, stated that the ministry could not take advantage of the offer a number of people had made to give in their lifetime one of their eyes to help save the sight of other persons who would otherwise be completely blind. The law on the matter is not certain, but it is possible that a surgeon's deliberately removing a sound eye from a living person, even with that person's consent, might be held to be a criminal offense. In any case it seems most unlikely that surgeons would be willing to perform such an operation. Arrangements for supplying the hospitals that carry out corneal grafting with eyes derived from patients who have died in hospitals are, however, being improved.

CORRESPONDENCE

INTERNSHIPS

To the Editor:—In the Aug. 25, 1956, issue of The Journal, I note that the House of Delegates passed a resolution to the effect that the Council on Medical Education and Hospitals be requested to discourage straight internships in all hospitals. At the Buffalo General Hospital, we have 18 rotating, 3 straight medical, and 3 straight surgical internships. Our staff has good reason to believe that the straight medical or straight surgical internships are superior for certain young graduates who have already had certain house staff experience. It is also our opinion that the type of internship should not be regimented or restricted, and, particularly, those hospitals whose primary objectives are the care of the patient, teaching, prevention of disease, and research should be left to do their own thinking. We in the field of hospital and medical care and medical education are keenly aware of and deeply grateful for the fine job being done by the Council on Medical Education and Hospitals, but we do not believe that the Council would desire or should be expected to carry out this function that it is now being subjected to.

Fraser D. Mooney, M.D.
Director, Buffalo General Hospital
Buffalo 3.

DEVELOPMENTAL DEFECTS

To the Editor:—The July 14, 1956, issue of The Journal contains an article by T. H. Ingalls (page 1047) on causes and prevention of congenital defects that, I feel, should not go unchallenged. It is the biologist's lot to investigate conditions of living organisms as they exist; even when he experiments, he only produces new constellations of preexisting factors and reactions. The biologist, and with him the medical scientist, cannot choose what fits his hypothesis and relegate the rest to convenient oblivion. Thus, it is difficult to agree with Dr. Ingalls that embryology should logically (or in any other way) precede genetics in the study of abnormal development. The more we learn about these fields, the less we can separate them or let one precede the other; the interested reader is referred to Waddington's "Principles of Embryology" (London, George Allen & Unwin, Ltd., 1956). The disregard of the importance of the ever-present action of genetic factors in all living organisms culminates in Dr. Ingalls' attitude toward the danger of mutations induced by modern sources of radiation. Against his statement that there is no substantial evidence of mutations produced by the atomic bomb in Hiroshima, one may hold (1) that no such evidence could possibly be expected to arise within a decade and (2) that an increased mutation rate has been demonstrated to occur after exposure to ionizing radiation in many organisms. It is interesting to see one man call the danger of mutations a macabre speculation, while 400 leading geneticists from all over the world pass a unanimous resolution that "the damage produced by radiation on the hereditary material is real and should be taken seriously into consideration" (News of Science, *Science* 124:358, 1956). One of the prominent features of mutations is that nothing can be done about them once they have occurred; this should qualify them eminently for a concerted effort of prevention.

The last few decades have seen a spectacular rise of scientific knowledge of abnormal development. By studying the actual sequence of developmental processes descriptively and experimentally, we have learned that the mechanisms entering into the formation of congenital defects are as numerous and varied as are those known in pathology of the adult. Owing to this variety, it is almost always impossible to figure out retrospectively the course of events on the basis of the final form seen at birth. Yet, Dr. Ingalls has availed himself of one "experimental model," the effect of hypoxia on mouse embryos, in order to explain all malformations. The sequence of events leading to abnormalities in these hypoxic mice has, as far as published records go, not been investigated by actual observation. We are led to believe implicitly, if not explicitly, that other teratogenic agents produce a stress equivalent to that of hypoxia and that all that matters is the timing of the event during embryonic life. How are we to reconcile this with much more thorough studies of malformations due to various chemical agents, vitamin deficiencies, and other insults, which can be produced in characteristic form by one or a few agents and never by others, regardless of timing? It may be very tempting to find an answer as simple as that given by Dr. Ingalls. But we can accept it no more than we would believe a statement that all diseases are caused by bacteria just because this was found to be true in one group of cases.

While we may not accept the simple and all-inclusive explanations offered by Dr. Ingalls, we should realize that here is a field as intricate and challenging as any in biology and medicine. From investigations of the actual happenings in abnormal development, and relevant information from many other disciplines, a body of knowledge is bound to evolve that will enable us to approach the goal for which Dr. Ingalls and I and many others strive, namely, the prevention of congenital abnormalities.

BIRTH OF TWINS

To the Editor:—In the Sept. 15 issue of The Journal, page 229, in Foreign Letters, is a report entitled "Twins Born Twelve Days Apart." In Canada, last year, there was a report of a "second child born 48 days after twin" (*Gazette*, Montreal, March 22, 1955), which, it was alleged, was "the second largest interval between the birth of twins on record. The longest known delay was 56 days." Of interest, therefore, is an authentic case in the Talmud of an interval of three months, and both not only were born alive but later were among the rabbinical authorities cited in the Talmud and known as "Judah and Hezekiah, the sons of Hiyya." Also of interest is the opinion expressed in the Talmud on the still controversial question of superfetation versus superfecundation. The present consensus among embryologists is, I believe, that, where a second child has been born a considerable time after the first and where both are fully developed, it was merely a twin pregnancy in which the second child had been slow in developing, because of a diminished blood supply or for some other cause. It is therefore noteworthy that this is also the opinion expressed in the Talmud.

SYNTHETIC OXYTOCIN

To the Editor:—In Foreign Letters in the Aug. 4 issue of The Journal, page 1410, under United Kingdom, appeared an item entitled "Synthetic Oxytocin" that is open to some misinterpretation. The impression is given that the oxytocin used in the investigations described was synthesized by the method of du Vigneaud. It is clearly stated by Bainbridge, Nixon, Schild, and Smyth (*Brit. M. J.* 1:1133, 1956) and by Francis and Francis (*Brit. M. J.* 1:1136, 1956) that the material was synthesized by a new method worked out by Boissonnas, Guttmann, Jaquenoud, and Waller (*Helvet. chim. acta.* 38:1491, 1955) and investigated pharmacologically by Konzett, Berde, and Cerletti (*Schweiz. med. Wchnschr.* 86:226, 1956) in the Sandoz Research Laboratories in Basel.

MEDICAL FILM REVIEWS

Surgical Treatment of Dissecting Aneurysms: 16 mm., color, sound, showing time 19 minutes. Prepared in 1955 by Michael E. DeBakey, M.D., Denton A. Cooley, M.D., and Oscar Creech Jr., M.D., Baylor University, Houston, Texas. Procurable on loan from Michael E. DeBakey, M.D., Baylor University College of Medicine, Texas Medical Center, Houston 25, Texas.

In this film, consideration is first given to the pathological features of dissecting aneurysms, with the demonstration effected by means of colored drawings of the characteristic pathological changes and the course of events that usually takes place in such a lesion. Two cases are presented, illustrating the two most common forms of the disease: (1) the type in which the dissection begins in the ascending aorta and (2) the type in which the dissection begins at or below the level of the left subclavian artery. The clinical manifestations and diagnostic features for both conditions are presented. This is an excellent film from virtually all standpoints. Use of the schematic drawings is handled well, and the x-rays are presented with remarks that clearly delineate the lesions. While the ingenious surgical technique should be of great interest to the vascular surgeon, the general practitioner should also be exposed to this teaching film chiefly because of the lucid description of the early symptoms and the necessity of early diagnosis and immediate action.

Operative Cholangiography: 16 mm., color, sound, showing time 17 minutes. Technical Advisors: Philip F. Partington, M.D., and Maurice D. Sachs, M.D., Cleveland. Produced in 1955 by and procurable on loan from Central Office Film Library, Veterans Administration, Washington 25, D. C.

The purpose of this film is to illustrate the technique of cholangiography and its advantages to the surgeon, radiologist, x-ray technician, and anesthetist. The authors deviate slightly from the usual routine of cholangiography, insofar as they observe the pressure in the common duct by means of a ureteral catheter in the cystic duct while they are injecting the Diodrast into the common hepatic duct. They use a concentration of Diodrast varying between 10 and 70%, depending upon the size of the common duct. They do not inject the Diodrast with a pressure greater than 20 cm. H_2O. Five cubic centimeters is injected and a roentgenogram taken. Two additional injections of 5 cc. are made, followed by taking of an x-ray film. If the common duct is opened to remove stones, a double-lumen T-tube is inserted and the process of injecting Diodrast and taking films is repeated to find out whether any stones have been left in the duct. The authors claim that this procedure will require little additional time. Since they are actually taking three to six films, one might question this statement. Almost certainly the method described would necessitate a lot of experience and almost full-time use of an x-ray technician in order for a large hospital to use the technique without loss of much time. The authors have expressed their points quite clearly. The only question that arises centers around the question as to how convinced one is that operative cholangiography is necessary as a routine procedure. The photography and animation are excellent. The film is well organized and concise and is very well done.

The Search: Johns Hopkins University (Deafness): 16 mm., black and white, sound, showing time 26 minutes. Produced in 1955 by CBS Television. Procurable on lease (10 years, $125) or rental ($5) from Young America Films, 18 E. 41st St., New York 17.

This film deals with a new approach to the diagnosis and treatment of deafness in children that is based on the theory that there is rarely, if ever, a total loss of hearing. The biggest stumbling block in the past has been determining what percentage of hearing exists in young children who have not yet learned to communicate and who, yet, should begin a training program as early as possible. The procedures of the hearing and speech center at Johns Hopkins University in Baltimore are explained by Drs. William Hardy and John E. Bordley as a 2½-year-old child undergoes preliminary tests to determine the extent of his hearing. The film also shows how children with hearing disabilities can lead full and useful lives if their hearing loss is detected and measured early enough and if they embark immediately on a guided training program. Children in various stages of training are shown. Near the end of the film it is mentioned that hearing loss is measured in decibels, but it is not specified where that loss is in the spectrum. It would be better to say 70-db. loss in the speech range. This film will be of interest to lay groups, particularly to mothers of children who have some hearing loss.

Magic of the Atom Series: 16 mm., black and white, sound. Produced in 1955 by and procurable on loan ($10 each) or purchase ($55 each) from Handel Film Corp., 6926 Melrose Ave., Hollywood 38, Calif.

Atoms for Health: Showing time 12 minutes.

The first part of this film illustrates a test of the ability of the liver to remove foreign substances from the blood stream. Radioactive albumin is injected into the blood stream to indicate, on a recording chart, the amount of blood flowing to the liver. When this registers, rose bengal is injected to carry additional radioactive iodine to the liver. The second part of the film shows a demonstration of the Theratron, a new cobalt source used in science's fight against cancer. A complete case history is followed, step by step. This is extremely interesting, inasmuch as physicians who visit cobalt-60 installations are not always privileged to see the actual rotation of the unit. The film is recommended for showing to lay audiences and also to physicians. The photography and narration are excellent.

Atomic Biology for Medicine: Showing time 12 minutes.

The purpose of this film is to show atomic biomedical research with animals, including the effect of radiation on the eyes, cell division, bones, and tumors. Dust inhalation studies are also described. This film is extremely valuable because of the wealth of technical effect implicit in every sequence. It is instructive to contemporary audiences who may not actually have seen the machining of uranium and the injection of radioactive beads into a tumor; it will be very valuable to future audiences as a documentary of 1955 techniques. The photography and narration are excellent, and the film is recommended for college biology classes and to medical audiences seeking to inform themselves about the use of radioactive preparations in medicine.

Hemipelvectomy, Interilioabdominal Amputation: 16 mm., color, sound, showing time 23 minutes. Prepared by George T. Pack, M.D., and Theodore R. Miller, M.D., New York. Produced in 1955 by Sturgis Grant Productions, New York, for and procurable on loan or purchase ($125) from E. R. Squibb & Sons, Division of Olin Mathieson Chemical Corp., 745 Fifth Ave., New York 22.

The purpose of this film is to show the authors' technique for performing a hemipelvectomy, involving interilioabdominal amputation, for a large rhabdomyosarcoma in the left femoral trigone. The patient shown is a 44-year-old female who had previously been admitted to a hospital with a lump in the left femoral trigone. A biopsy was done; the unencapsulated and diffusely infiltrating tumor was reported to be a rhabdomyosarcoma. Because of the size, fixity, invasive nature, histogenesis, and location of the tumor, it was decided that hemipelvectomy be done. The patient is shown three months after the operation, learning to use her artificial limb. She is able to sit comfortably and to walk with one cane; the scar is shown to be well healed. The technique of hemipelvectomy is well demonstrated, and the film in general is excellent. The film concludes with a review of two patients walking in a prosthetic device that has been devised for this type of patient. The patients walk very well; however, they are in the younger age group, and possibly this is a little exaggeration of what the usually more elderly patient can do. This film is recommended for specialists and those surgeons who are interested in this procedure.

Scare Story—A True Story About Hospitals: 16 mm., color, sound, showing time 16 minutes. Produced in 1955 by Impact Productions, under the sponsorship of the Childrens Hospital of Los Angeles. Procurable on rental ($4) from American Hospital Association, 18 E. Division St., Chicago 10.

This film consists of a prologue, entitled "Scare Story," that is designed to be shown to hospital personnel only. It dramatizes the fears a child might have if not properly prepared for hospital admission. The film, "A True Story About Hospitals," follows a boy and girl from the time they first meet the admitting clerk through their whole hospitalization. Through the children's eyes, the audience comes into contact with the x-ray camera, intravenous feeding, an oxygen tent, blood tests, anesthesia, and the operating room. By the time the children are ready to go home, they have witnessed almost all the ordinary hospital procedures. This is an excellent film for the orientation of children to the hospital experience; it will be particularly valuable where the services of a local hospital approximate those shown in the film so that the experiences can be comparable. However, the prologue is unnecessary and should be removed. This film will also be of value is acquainting hospital personnel, including physicians, with some of the attitudes and behavior toward children in the hospital situation.

THE LEISURE CORNER

THE LOS ANGELES DOCTORS' SYMPHONY ORCHESTRA

Creating music interpretatively together with others provides a satisfaction over and above that found in just listening to good music. The members of the Los Angeles Doctors' Symphony Orchestra and of doctors' orchestras in other cities have found that playing in the orchestra provides good fellowship and aids in promoting culture in the community.

The Los Angeles group finds that these activities play an unusual public relations role, by revealing another important side of the doctor. Direct assistance to worthwhile medical causes is rendered by playing benefit performances; this orchestra generally plays two each year: one in the winter for its permanent beneficiary, the Los Angeles County Physicians Aid Association, and a second in the spring for different beneficiaries. A highlight of the forthcoming third annual formal concert will be the appearance of Mr. Donald O'Connor, who will be guest conductor of a symphony he is writing for a movie that he expects to produce. This concert, for Physicians Aid, will take place at the Los Angeles Philharmonic Auditorium on Jan. 12, 1957.

The orchestra has just started its fourth season. There are 90 members, mostly M.D.'s, with a fair representation of dentists, veterinarians, chiropodists, and physicians' wives. General practice and virtually all medical specialties are represented. The largest group of members are psychiatrists. While most of the positions are filled, several openings exist, particularly in the cello, bassoon, and English horn sections.

This orchestra has enjoyed the good fortune of having Mr. William Van den Burg as conductor and music director since its inception. Mr. Van den Burg combines the rare talents of fine musicianship and the diplomacy that is essential to weld so many "rugged individualists" into a professional-sounding ensemble. He is currently principal cellist at Universal Studios and formerly was principal cellist and assistant conductor with Stokowski, Monteux, and Wallenstein. After the weekly rehearsals in a Hollywood junior high school, a number of the orchestra members can be found relaxing over coffee in a restaurant near the famous corner of Hollywood and Vine. As might be expected, most of the discussion concerns medicine and music.

Benjamin Gross, M.D., of North Hollywood, concertmaster of the orchestra, was formerly concertmaster of the Louisville Symphony Orchestra and is now a rare combination of pathologist and psychiatrist. The president is Jerome M. Kummer, M.D., a Santa Monica psychiatrist, who is also principal in the bass violin section. Dr. Arthur M. Grossman, vice-president, plays the flute; he practices pediatrics in Beverly Hills. Jack Fields, M.D., an ophthalmologist from North Hollywood, occupies the principal chair in the trumpet section and is secretary-treasurer. Mrs. John (Shirley) Brody, librarian, plays in the viola section; her husband, a Beverly Hills anesthesiologist, is a cellist with the orchestra.

There are several ex-professional musicians in the orchestra. In addition to Dr. Gross, there is M. Richard Ferguson, M.D., principal trombonist, who formerly played with name bands, the last one being Stan Kenton's. Dr. Ferguson practices orthopedics in Santa Monica. Dr. Samuel Hoffman, the only chiropodist in the orchestra, plays in the first violin section and has the distinction of being the only member who does some professional work in music. He plays the theremin, an unusual instrument that produces an unusual tone electronically; the pitch is controlled by the player never touching the instrument, but moving his hands near it. Dr. Hoffman has played the theremin in many film sequences. He will long be remembered for his performance during the dream sequel in the film "Spellbound."

Through the years The Journal has published news items concerning doctors' orchestras in New York, Detroit, Akron, St. Louis, Chicago, Washington, D.C., San Francisco, and Los Angeles. The Akron doctors' orchestra, under the able leadership of its director, Dr. A. S. McCormick, has just completed its 30th season, having given 193 concerts in that time. In addition to doctors' orchestras, there are numerous smaller groups of physicians devoted to the better known works of chamber music, and some to the still better known works of Dixieland jazz. Much has been theorized on the attraction of doctors toward music and the relationship between medicine and music. It is possible that this was recognized by the ancient Greeks, since Apollo, the god of music, was the father of Aesculapius, the god of medicine.

No statement from the Los Angeles Doctors' Symphony Orchestra can be considered complete without a tribute to its impressario, Dr. Elizabeth Mason Hohl, president of the Physicians Aid and liaison officer with the Los Angeles County Medical Association, whose officers and staff have always proved of great assistance.

Los Angeles Doctors' Symphony Orchestra, William Van den Burg conducting.

collagen diseases, they seem to occur more frequently in patients with these diseases than in other people of the same age. Therefore, the coexistence or future development of a malignant tumor should always be considered in this group of patients.

Gastric Biopsy in the Megaloblastic Anaemias. J. L. Markson and W. M. B. Davidson. Scottish M. J. 1:259-266 (Aug.) 1956 [Glasgow, Scotland].

The introduction of a flexible suction gastric biopsy tube by Wood and his colleagues in Australia made available a simple and relatively safe method of obtaining fragments of the gastric mucosa for histological study. Markson and Davidson describe the histological appearances of gastric samples taken from patients with pernicious anemia and other megaloblastic anemias. Biopsy revealed gross atrophy of the gastric mucosa in all 16 patients with pernicious anemia. Minor inflammatory changes were found in four of the cases of gastric atrophy. In two of the remainder, thickening and fibrosis of the muscularis mucosae, indicative of previous inflammation, was present. Normal mucosa was found in four patients with megaloblastic anemia of pregnancy. Of three patients with megaloblastic anemia and idiopathic steatorrhea, one had normal mucosa and two had atrophic gastritis.

The histological findings in pernicious anemia were compared with those obtained in iron-deficiency anemia and in a series of nonanemic hospital inpatients. The abnormalities of the gastric mucosa were not diagnostic and did not differ materially from severe lesions encountered in the other two groups. The lack of diagnostic information yielded by gastric biopsy and the real, though slight, risk of hemorrhage limit the value of the procedure in the diagnosis of doubtful cases of pernicious anemia and of subacute combined degeneration of the cord. Since the gastric mucosa is nearly always grossly abnormal in histamine-fast achlorhydria, it is safer and almost as useful to rely on the result of the histamine test meal. The histological evidence obtained by gastric biopsy strongly suggests that there is a gradation from normal mucosa through superficial and atrophic gastritis to gastric atrophy. This sequence of events is not necessarily an invariable occurrence in pernicious anemia, in which gastric atrophy may also occur as a genetically determined characteristic.

Clinical Contribution to the Use of Hyaluronidase in the Treatment of Edema and Ascites. Riforma med. E. Bellis and M. Campilonzo 70:907-910 (Aug. 11) 1956 (In Italian) [Naples, Italy].

The authors treated 10 patients with edema and ascites with hyaluronidase. Four patients had cirrhosis of the liver, five had heart disease, and one had nephritis. The drug was given by subcutaneous, intravenous, intramuscular, and intraperitoneal routes. Subcutaneous and intramuscular injections gave poor results and were abandoned after preliminary experiments. Doses given intravenously consisted of 500 units daily every day for a period of from 5 to 15 days. Three patients received intraperitoneal injections of 1,000 units every other day for four days. The diet was kept normal. The urine was tested. The circumference of the abdomen was checked. Hyaluronidase had a very good effect on patients with relatively good circulation. Intravenous injection was the best method of administering the drug. Intraperitoneal injections gave poor results in patients with ascites. Diuretic substances improve the effect of hyaluronidase. The drug was well tolerated by all patients.

A Clinical Study of Scrub Typhus in North Queensland. R. L. Doherty. M. J. Australia 2:212-219 (Aug. 11) 1956 [Sydney, Australia].

This report is based on a series of 53 patients with scrub typhus studied at a station of the Queensland Institute of Medical Research from March, 1953, to November, 1954. Rickettsia tsutsugamushi was isolated from 45 of these patients by mouse inoculation. Proteus agglutination tests were performed on paired serums from all patients and confirmed the diagnosis in the eight cases in which no strain was isolated. The clinical picture was milder than that described in preantibiotic Queensland series, although several patients had severe illnesses. Lymph-node enlargement, rash, and eschar were the commonest findings on physical examination. Several points of correlation could be demonstrated between the clinical picture and the virulence of the causative organism in mice. The course of the disease reflected the influence of treatment, especially in the total duration of fever. Forty-five patients were treated with chloramphenicol, two with tetracycline, and one with chlortetracycline. The results were satisfactory, but in seven the response was less rapid than expected. Nine patients had relapses after responding to treatment. Seventeen patients did not develop agglutinins against Proteus OXK, and in seven others a diagnostic titer was not reached. The factors that may have influenced this are discussed, and some evidence is presented that mild strain infections, treated with an effective antibiotic early in the illness, are more often OXK-negative.

The Use of Butazolidine in Gonococcal Arthritis. N. P. Burns. M. J. Malaya 10:313-319 (June) 1956 [Singapore, Malaya].

Gonococcic arthritis is still frequent in the Ulu Kelantan district in Malaya, where gonorrhea is still prevalent. Burns reports observations on 15 patients with this form of arthritis. The interval between acute urethritis and gonococcic arthritis varied from two weeks to several years. The arthritis may be monoarticular or polyarticular. In a typical case the onset is explosive, with two or three large joints becoming hot, swollen, and tender, with mobility reduced by pain, often of excruciating severity. Many of the other joints, although not hot or swollen, become painful. After a varying interval, usually about one month, the acute stage of the disease settles but the patient is left a semi-cripple as a result of severe pain arising from the periarticular tissues and evoked by movement of the neighboring joint. Pain may also be present at rest. The subsequent course of the disease is one of exacerbation and remission. The 15 patients were men ranging in age between 15 and 40 years. Six had the monoarticular and nine had the polyarticular form of gonococcic arthritis. Symptoms had existed for an average of five years. Treatment had varied from native remedies to high dosage courses of penicillin and other antibiotics. Response to all forms of treatment had been poor. Administration of butazolidine was started with a single intramuscular injection of 600 mg., followed by 400-mg. tablets twice a day for five days. Although the original idea of commencing treatment intramuscularly was for purely psychological reasons, in fact the objective response produced by an injection, as assessed by diminution of swelling, increase in joint mobility, and rapidity of response, was more dramatic than that produced by a comparable dose given orally. Since butazolidine was given not to cure or eradicate the disease but merely to control its symptoms, subsequent therapy was given only when symptoms recurred. When gonococcic arthritis is controlled by intermittent courses of butazolidine, the toxic reactions are few. Butazolidine is a valuable agent in the treatment of gonococcic arthritis and worthy of trial in cases not responding to other methods.

Endocarditis Lenta: A Review of 118 Patients Treated During the Ten-Year Period 1945 to 1954. W. J. Kaipainen and K. Seppala. Acta med. scandinav. 155:71-81 (No. 1) 1956 (In English) [Stockholm, Sweden].

The authors report on 118 cases of subacute bacterial endocarditis treated in the First and Second Medical Clinics of Helsinki University during the period from 1945 to 1954. Positive blood cultures were obtained in 36% of the cases. Unless the blood culture was definitely positive or ulcerative-verrucous endocarditis was verified at autopsy, the following were the criteria governing the selection of the material: (1) valvular disease or congenital heart disease, (2) prolonged fever, (3) anemia, (4) focal embolic nephritis, and (5) an increased sedimentation rate.

The patients were divided into four groups: (1) 18 who received sulfonamide treatment or no antibacterial treatment at all; (2) 39 who received penicillin in a total dosage of less than 15 million units each; (3) 21 who received penicillin in a total dosage of more than 15 million units each; and (4) 38 treated with penicillin and other antibiotics. Many of the patients in group 4 received an average of from 1 to 2 million units of procaine penicillin in combination with 1 gm. of tomycin, each in two doses per 24 hours. The total penicillin ge in many cases exceeded 50 million units. Evaluation of esults six months after treatment was started showed a val rate of 0% in group 1, 20.5% in group 2, 67% in group d 68% in group 4. Two additional patients, one of whom treated with a total dosage of 24.5 gm. of streptomycin the other, because of allergy to penicillin, with 32 gm. of mycin, recovered and were living, the first six years and econd two and one-half years after the beginning of the nent. The final mortality rate (after 6 months) was higher oup 3 than in group 4, but whether this was because illin in large doses alone is a poorer therapeutic measure penicillin in combination with other antibiotics is open to ion. The infection in these cases was halted and the nts died of other causes, e. g., exacerbation of cardiac e due to the valvular lesion or cerebral and other emboli. tients with suspected subacute bacterial endocarditis should time be left untreated, even when the blood cultures are ive. The cultures may be negative for one or more technical reasons, and treatment should not be postponed until a ve culture is obtained. The low percentage of positive res obtained in the present series, only 36%, for instance, have been due to (1) too few samples, (2) samples taken ng or immediately after antibiotic treatment, (3) failure of pling technique, and (4) failure of cultivation technique.

xperience in some of these cases showed that the pain of reed intramuscular injections can be avoided by the use of aine penicillin in combination with streptomycin; in others, im treatment with tetracycline preparations was given for, a week without untoward effects. Antibiotics should be n prophylactically to patients with valvular lesions and genital heart lesions who are to undergo dental or surgical edures usually accompanied by the temporary liberation of eria into the bloodstream.

of Radioactive Iodine for Intractable Angina Pectoris. A. M. lman. J. Louisiana M. Soc. 108:337-343 (Sept.) 1956 [New ans].

oldman reports observations on 13 euthyroid patients who e treated with radioactive iodine (I^{131}) for angina pectoris r all conventional forms of therapy had failed. Seven of the ents were women and six were men, their ages ranging from to 79 years. A tracer dose of $50\mu c$ was used, and the uptake measured at a distance of 17 cm. directly over the gland. rmal uptake of I^{131} is considered to be between 10 and 40% the tracer dose in 24 hours. A single large therapeutic dose s used in all 13 patients, because it was desired to shorten period of irradiation and secure an earlier onset of hyporoidism. This single dose resulted in postirradiation thyroid-, release of large amounts of thyroid hormone, and exacertion of the patients' symptoms. Since this course has proved wise, future patients will be treated with divided doses.

Five of the patients died, three from acute myocardial inction, one after the development of acute pulmonary edema, d one from cerebrovascular accident. A lymphoblastic lymoma developed in one patient nine months after administraon of the treatment dose. It is interesting to note that this tient has several sisters and brothers with malignant disease. he follow-up period of the eight surviving patients now varies om two to five years. The effect on the angina was excellent five of the eight survivors, good in one, and fair in two. The set of clinical improvement coincided with the appearance f signs of myxedema. No toxic effects were noted on the hemaopoietic system or the kidneys. The surviving patients are being naintained on minimal doses of thyroid extract to prevent clinical myxedema. The favorable results obtained in the survivors seem to warrant further careful study of this method of relieving intractable heart disease.

Eyeball Bruits. J. H. Cohen and S. Miller. New England J. Med. 255:459-464 (Sept. 6) 1956 [Boston].

Eyeball bruits were discovered in seven patients admitted to the medical service of a 370-bed general hospital during a two-year period. Two cases were proved, and one was suspected, to be due to arteriosclerotic narrowing of the carotid siphon. One case was proved to have been caused by internal carotid artery thrombosis in the cavernous portion. The bruit was bilateral in the remaining three cases, one of which was due to hemangioma and the other two to profound anemia. The quality of the bruits was similar in all seven patients, but their intensity varied from patient to patient and also from time to time in the same patient. All the bruits were synchronous with the heartbeat and were systolic in time. They could be made to disappear by pressure on the ipsilateral common carotid artery. The sound itself was a soft blowing murmur, and before it could be heard the stethoscope often had to be placed with just the right amount of pressure and the patient had to be asked to hold his breath while either the examiner held the other eye closed or the patient opened it. Sounds that were inaudible over the orbital bones or other nearby structures could often be heard when the stethoscope was applied to the eye itself. Auscultation should therefore routinely include the application of the stethoscope to the eye itself, sepecially in cases of neurological or circulatory disease in which no bruit can be heard over the cranium. The examination should be made with the patient in the sitting and the supine positions, as well as lying on each side.

The relative frequency of eyeball bruits, especially those caused by occlusion and narrowing of the cavernous portion of the internal carotid artery, suggests that auscultation of the eyeball itself will often supply valuable information in the diagnosis of cerebrovascular diseases and that it should be more widely used.

Progressive Pulmonary Dystrophy: Vanishing Lung (Burke), Idiopathic Pulmonary Atrophy (de Martini). L. Heilmeyer and F. Schmid. Deutsche med. Wchnschr. 81:1293-1297 (Aug. 17) 1956 (In German) [Stuttgart, Germany].

Heilmeyer and Schmid are concerned with a pulmonary disorder that they feel should be differentiated from the different forms of pulmonary emphysema or pulmonary cysts, the more so since the pulmonary destruction goes deeper than in the case in the ordinary substantial pulmonary emphysema and involves not only the peripheral pulmonary tissues but also the proximal parts of the pulmonary vessels and of the bronchial tree. The lesions are usually not diffuse but involve only one lobe of a lung. Similar cases were formerly described under the general heading of pulmonary emphysema. Crenshaw spoke of "vanishing lung" or "cotton candy lung." Burke in his first description of "vanishing lung" believed that the process was an emphysema with vesicles of enormous size so that a gigantic emphysema vesicle might eventually fill an entire lobe. In Italy cases were described by de Martini, who differentiated them from the various forms of emphysema as well as from pulmonary cysts and who spoke of idiopathic pulmonary atrophy. In Germany cases of this type were usually described under such terms as pulmonary cysts or spontaneous pneumothorax.

The five patients whose histories are presented all had pulmonary lobes or parts of lobes in which the pulmonary tissue, including the proximal portions of the bronchi and vessels, had been completely destroyed. This destruction may produce cyst-like cavities, as was the case in two of the patients. In three of the patients who were observed over a number of years and in whom roentgenograms were made repeatedly, the condition was definitely progressive, whereas it remained constant over 15 years in the first case. The progressiveness of the process in three of the patients differentiated the condition from idiopathic pulmonary atrophy as described by de Martini, and for this reason the authors prefer the term "progressive pulmonary dystrophy."

Pulmonary or bronchial infections existed at the onset in four of the patients. Two of these also smoked excessively and another patient worked with tobacco. The abuse of nicotine as a possible causal factor was also mentioned by Crenshaw, who, moreover, was of the opinion that the destruction of the lung was caused by obliteration of the bronchial and pulmonary arteries. This simultaneous occlusion of the bronchial and pulmonary arteries is also regarded as an important factor by the authors. They believe that an inflammatory endarteritis obliterans is one of the primary causes and suggest that infection of the lung leads to sensitization of the vessels. Pulmonary dystrophy would then be the sequel of a Buerger's disease of the pulmonary and bronchial arteries. The frequent concurrence of infection with severe abuse of nicotine would fit into this concept. As regards treatment, attention should be given to the accompanying infections because these may favor further progression of the pathological process. Crenshaw is of the opinion that surgical therapy would be advisable, particularly after the atrophic pulmonary tissue loses its elasticity and the bullous emphysema causes compression of the healthy portions of the lung. This may apply particularly to processes characterized by emphysema with enormous vesicles and perhaps also to patients with pseudocysts. The authors believe, however, that in the purely dystrophic form without compression of the surrounding tissue surgical treatment is not indicated, unless it can be proved that the exclusion of the inflammatory process in the dystrophic portion of the lung will arrest the progress of the disease.

Idiopathic Ulcerative Esophagitis: Report of a Case. H. Achenbach, J. P. Lynch and R. W. Dwight. New England J. Med. 255:456-459 (Sept. 6) 1956 [Boston].

Idiopathic ulcerative disease primary in and confined to the esophagus appeared in a 25-year-old man first seen because of tenderness and discharge in the anal region. He had had recurrent episodes of tenderness in that region relieved by spontaneous drainage for more than a year. The first such episode had occurred during service in Korea. The patient was well developed and had no physical defects except one abscess and three fistulous openings in the perianal region. Laboratory findings were normal except for a hemoglobin level of 11.5 gm. per 100 ml. Two readmissions for similar complaints took place later in the same year, and on each of these occasions biopsy of a fistulous tract showed granulation tissue with nonspecific chronic inflammation. Migratory arthritis, erythema nodosum, and dermatitis gangraenosa appeared in connection with the persistent multiple perianal abscesses and fistulas. Painless dysphagia, which was the initial symptom of the primary esophageal disease, began nine months after the first hospital admission. Thickening of the longitudinal folds of the esophagus seen on x-ray examination was the first demonstrable esophageal abnormality. The mucosa became fissured and then ulcerated, with undermining and pseudopolyp formation. The esophagus lost its motility and became stenotic and obstructed. Multiple perforations caused abscesses in the upper lobe of the right lung and in the mediastinum. Esophagectomy, performed as a lifesaving procedure, was followed by gradual improvement. Drainage from the anal region subsided spontaneously. The arthritis, erythema nodosum, and gangrenous skin ulcers, which were becoming more severe and widespread despite cortisone and antibiotic therapy, were also resolved. All these have been described as complications of ulcerative colitis, and when they occur this diagnosis must be considered even in the absence of colonic symptoms. The origin of these complications is not understood. They may represent toxicity from a gastrointestinal tract that is more than normally permeable or a decrease in resistance to infection in a chronically ill patient, or they may be an integral part of a disease complex.

The diagnosis of ulcerative colitis was often considered in this patient, but it was never substantiated by barium-enema study or sigmoidoscopy. The curative effect of esophagectomy on the associated conditions was the same as that of colectomy in ulcerative colitis. No similar cases have been found in the literature.

A Clinical Trial of BZ-55. L. J. P. Duncan, J. D. Baird and D. M. Dunlop. Brit. M. J. 2:433-439 (Aug. 25) 1956 [London, England].

Carbutamide (BZ-55) was given a trial in 44 patients over 45 years of age with mild diabetes mellitus who were not overweight by more than 10% of their ideal weight but who, on a fully restricted diet, continued to show significant hyperglycemia and glycosuria and, therefore, required insulin therapy in addition to dietary measures. One group of 22 patients remained in the hospital for 20 days, while a second group of 22 patients was hospitalized for 8 days only. Although most factors were kept constant throughout for all patients, the diets were individually prescribed and the dosage of carbutamide was adjusted according to the clinical response. Treatment was started with 3gm. (six tablets) given by mouth before breakfast in 12 patients and with 4.5 gm. in 32 patients. Blood was withdrawn at hourly intervals for five hours thereafter, and its glucose and carbutamide content were determined. The patients remained in bed and food was withheld during the period of the test. If the response was satisfactory, the dose was gradually reduced over three or four days to 1.5 gm., but if the response was inadequate, 4.5 gm. was given daily for several days. Patients whose response was considered to be clinically satisfactory were discharged on a daily maintenance dose of carbutamide varying from 1 to 1.5 gm.

Sixteen patients in group 1 and 16 patients in group 2 responded well enough to the drug to be classed as clinical successes. Three patients in group 2 responded to the drug but were clinical failures. Nine patients did not respond to continued treatment with carbutamide. In responsive patients who were also clinical successes, the drop in fasting blood glucose was roughly proportional to the fasting blood-glucose concentration in the control period. In the unresponsive patients there was no such relationship. The three responsive patients who were clinical failures occupied an intermediate position. Glucose-tolerance tests showed that carbutamide is without effect on glucose tolerance. The drug was without effect on ketosis or on patients who readily developed ketosis. Follow-up studies of the discharged patients for from 4 to 18 weeks showed that maintenance treatment with carbutamide must be continuous and not intermittent. Minor toxic effects were observed in several patients, and there appears to be a possibility that thrombocytopenia may occur. The difficulties encountered in selecting the responsive patient and the dangers of withdrawing insulin in the unresponsive patient are emphasized. Carbutamide should not be given as a substitute for dietary restriction. When this principle is observed, the number of patients in whom it can replace insulin is more limited than reports to date have suggested.

Trial of an Oral Hypoglycemic Agent in Diabetes. F. W. Wolff, G. A. Stewart, M. F. Crowley and A. Bloom. Brit. M. J. 2:440-445 (Aug. 25) 1956 [London, England].

Thirteen men and 32 women, 6 between the ages of 21 and 40 years, 13 between the ages of 41 and 60, and 26 between the ages of 61 and 80, with diabetes mellitus normally requiring insulin, were admitted to hospital, were given a diet suitable for their physique and metabolic needs, and were maintained on this diet alone without insulin for five days. For the next two days no breakfast was given, but on the second day an initial dose of 2.5 or 3.5 gm. of carbutamide (BZ-55) was given in the morning. Except for the young ones, the patients received a dose of 2 gm. on the following morning, followed by 1 gm. daily for at least five days as inpatients and then as outpatients. In poorly controlled patients, administration of 3 gm. daily was begun on the eighth day and continued for five days. In some patients rapid loss of weight and ketosis necessitated an earlier resumption of insulin therapy, which also became necessary occasionally in those in whom trebling of the dose was attempted.

Nineteen patients were clinical successes and 26, including the 6 young patients, were therapeutic failures. The patients in whom carbutamide was successful frequently had a history of diminishing insulin requirements. In none of these was the fasting blood sugar level greater than 275 mg. per 100 cc., and the fasting range was from 123 to 275 mg. per 100 cc. The patients in whom carbutamide failed tended to have a higher insulin requirement than those in whom it was successful. Their fasting blood sugar levels ranged from 123 to 421 mg. per 100 cc., and they had a tendency to acetonuria. Carbutamide did not exert any influence on the postprandial rise in blood sugar levels, either in the group of successes or in that of failures. There was no difference in levels between free and conjugated sulfonamides in the blood between successes and failures. There was more excretion of conjugated sulfonamides in the urine of the patients in whom the drug failed than in those in whom it was successful. Five patients (11%) had skin reactions to carbutamide. In four of them carbutamide was replaced by N-(4-methylbenzosulfonyl)-N′-butylurea (D860), which has hypoglycemic properties similar to those of carbutamide although it is not a sulfonamide preparation, and the typical maculopapular sulfonamide rash then gradually disappeared.

Myotonia Atrophica with Testicular Atrophy: Urinary Excretion of Interstitial-Cell–Stimulating (Luteinizing) Hormone, Androgens and 17-Ketosteroids. B. G. Clarke, S. Shapiro and R. G. Monroe. J. Clin. Endocrinol. 16:1235-1244 (Sept.) 1956 [Springfield, Ill.].

It has been suggested that dystrophia myotonia (myotonia atrophica) may represent a pluriglandular disturbance of endocrine origin and be susceptible to treatment by endocrine replacement therapy. An alternative interpretation is that, instead of reflecting a primary endocrine disturbance, dystrophia myotonia is simply a manifestation of genetically linked degenerative phenomena seen in various tissues derived from embryonic ectoderm and mesoderm. It has been defined as "a steadily progressive, familial, distal myopathy with associated weakness of the muscles of the face and levators of the eyelids, tendency to myotonic persistence of contraction in the affected parts, and testicular atrophy." The authors found the records of seven patients with dystrophia myotonia in the files of their own hospital, and all had testicular atrophy. They found atrophy of the testes recorded also in 65 of 81 male patients with myotonia atrophic collected from the literature. Detailed clinical, endocrine, and histological studies were carried out on two typical cases. Histological observations on testicular tissue were correlated with measurements of urinary excretions of androgens, luteinizing (interstitial-cell–stimulating) hormone, follicle-stimulating hormone, and 17-ketosteroids.

In the first patient the disease began at the age of 10 years and in the second at 26 years. Muscular weakness and atrophy were local in the first patient, being confined chiefly to head, neck, forearms, and hands, although myotonia was pronounced. In the second patient, weakness and atrophy were generalized and tended to obscure the myotonia. As anticipated, the serum creatine level and urinary creatine excretion were elevated. In both men the testes were small and soft, the size of peas. Biopsy of the testes showed normal or increased interstitial cells in association with atrophy of the spermatogenic tubules. Assays of the urine showed follicle-stimulating hormone to be normal, 17-ketosteroids low, luteinizing (interstitial-cell–stimulating) hormone greatly increased, and androgens greatly reduced. No other evidence of endocrine disturbance was observed. Although there have been reports on endocrine replacement therapy in the form of testosterone propionate, corticotropin, and cortisone in patients with dystrophia myotonica, the results appear to have been poor or equivocal.

Treatment of Eczema Vaccinatum by Specific Gamma Globulin: A Case Report. M. J. Fox and V. B. Pica. Wisconsin M. J. 55:972-976 (Sept.) 1956 [Madison, Wis.].

A 57-year-old man had a severe vaccinia after contact with his 18-year-old daughter, who had had a chronic eczema all her life and who had received a routine smallpox vaccination that was followed by a severe pruritic, macular, papular, and vesicular eruption on her face and body. The father had helped her to the bathroom, had handled her eating-utensils, and had direct contact with her towels and linen. The same vesicular eruption as in the daughter occurred over the face, scalp, and body of the father. On admission, there was edema and pain in the face, marked headache, tinnitus, pruritus, fever, conjunctival injection, photophobia, dryness of the mouth, nausea, malaise, and general arthritic joint pain. The patient was given 30 cc. of vaccinia globulin intramuscularly. Shortly thereafter his temperature returned to normal. Improvement of the eczema vaccinatum was rather rapid, and the patient's condition remained stable until discharge eight days later except for one febrile episode on the day after the vaccinia globulin injection. Vaccinia immune globulin has an important place in the prevention and treatment of serious complications of smallpox vaccination, particularly eczema vaccinatum.

Milkers' Nodules. C. E. Wheeler and E. P. Cawley. South. M. J. 49:973-978 (Sept.) 1956 [Birmingham, Ala.].

Wheeler and Cawley became interested in milkers' nodules in 1952, when they observed two patients with this disease in Virginia. The histories of these two patients and of six others observed later are described. The lesion appears first as a tiny, round, erythematous macule that soon becomes thickened to form a papule and slowly grows until it reaches the diameter of a centimeter or slightly larger. It attains its full size in about four weeks, remains essentially static for approximately two weeks, and gradually resolves without scar formation, the entire course of the uncomplicated lesion taking from six to eight weeks. The mature lesion is usually round, sharply demarcated from the surrounding skin, and dome-shaped. Some of the lesions have a flat or plateau-like top. One or two lesions are most commonly seen, but sometimes six or eight appear. When large numbers of lesions are seen, the disease is usually not milkers' nodules but true cowpox (vaccinia), and laboratory studies will demonstrate the true etiology.

Milkers' nodules appears to be an infectious disease. The disorder almost always appears first in the cow, and man contracts it on the parts most exposed to the lesions on the cow, i. e., on the hands and forearms. The lesions in the cow are variously described by patients and veterinarians as warts, pimples, scabs, crusts, vesicles, and pustules on the teats or udders. Several lesions are usually present, but aside from local soreness the cow is not affected systemically. A viral cause has been assumed for milkers' nodules, and there have been a few reports on inclusion particles in the epidermal cells of the lesion. Attempts to transmit the disease by inoculation of tissue suspensions and fluid from the lesions to experimental animals have been unsuccessful. Veterinarians have been unable to transmit the disease to cows and calves.

The Usefulness of Corticotropin and Corticoids in Patients with Liver Disease. M. A. Spellberg. Am. J. Gastroenterol. 26:342-353 (Sept.) 1956 [New York].

Corticotropin (ACTH), cortisone, and hydrocortisone were used as therapeutic agents in 10 patients with various diseases of the liver. In a 27-year-old man with infectious hepatitis, intravenous administration of 20 units of corticotropin daily was started at the end of the fourth week of his illness when the serum bilirubin level was 40 mg. per 100 cc. There was a nearly 50% drop of the serum bilirubin level within one week. Treatment with the same dose of the hormone was continued for two weeks and then gradually discontinued. The icterus disappeared in about four weeks, and the patient made an uneventful recovery. A 17-year-old boy with posthepatitic cholangiolitic cirrhosis started receiving 50 mg. of cortisone intramuscularly twice daily when his serum bilirubin level had increased to 24 mg. per 100 cc. after a temporary drop to 16.8 mg. per 100 cc. resulting from absolute bed rest and intravenous administration of dextrose and vitamins. The serum bilirubin level dropped again to 8.4 mg. per 100 cc. in two weeks. There was marked improvement of appetite and weight gain. After three weeks of treatment with cortisone, 40 units of corticotropin gel was given intramuscularly as a substitute for cortisone. This dose was gradually reduced and then withdrawn, but the serum bilirubin level rose again to 21 mg. per 100 cc. The jaundice could practically be titrated with the steroids. Steroid therapy had to be continued for about 18 months, after which time the liver was apparently able to function without assistance. No fatty liver developed in this patient.

Only one of six patients with hepatic coma (three with posthepatitic cirrhosis and one each with chronic, subacute, and acute hepatitis) who were given corticotropin and corticoids, survived and is still alive eight months after her first attack of coma. This was a 25-year-old woman who had had infectious hepatitis about six years previous to her admission to hospital for hepatosplenomegaly and jaundice in the fifth month of pregnancy. She delivered a premature but viable infant and three days later went into hepatic coma. She was out of coma after 72 hours of intravenous administration of 100 units of corticotropin daily. Two weeks after the treatment was changed to intramuscular administration of 40 units of corticotropin daily, she again went into hepatic coma. Administration of 100 units of corticotropin intravenously resulted in the patient's return to the precoma state within 48 hours. The patient was discharged four weeks after the last episode of coma on 40 units of corticotropin given intramuscularly. The postpartum hepatic coma may have been caused by a spontaneous reduction of endogenous adrenal steroids at the termination of pregnancy, and it was necessary to stimulate her adrenal glands more vigorously with large amounts of corticotropin. A 48-year-old man had a cholecystectomy and common duct exploration and drainage one year before jaundice recurred. There was a prompt drop of the patient's serum bilirubin level on administration of 100 mg. of cortisone intramuscularly. The patient was subsequently operated on again, and a carcinoma of the pancreas was found. This case shows that even in carcinoma of the pancreas the jaundice may be caused by an associated pancreatitis that responds to the anti-inflammatory influence of steroids. The last patient, a 57-year-old woman, who six years before had had a cholecystectomy for cholelithiasis, underwent an exploratory laparotomy because of epigastric pain, nausea, vomiting, pruritus, and jaundice. Liver biopsy showed an intrahepatic cholangitis. Pain and jaundice continued postoperatively. She was placed on therapy with 60 units of corticotropin gel, and the jaundice disappeared rapidly and completely.

Corticotropin and corticoids are useful therapeutic agents in protracted hepatitis with jaundice, fulminating hepatitis, hepatic coma, posthepatitic cholangiolitic cirrhosis, and perhaps other types of biliary cirrhosis. Steroid therapy may be of limited value in certain phases of portal cirrhosis, and it may have some limited value as a therapeutic test in differentiating between "medical" and "surgical" jaundice.

Lupus Vulgaris After BCG Vaccination. G. Høvding and P. Wetteland. Nord. med. 56:948-950 (July 5) 1956 (In Norwegian) [Stockholm, Sweden].

A case of lupus vulgaris at the site of BCG vaccination in a 46-year-old woman is described. The patient was Pirquet negative before the vaccination and had lived in a nontuberculous milieu for years. One week after inoculation in the shoulder by the multiple puncture method in January, 1950, local itching and exudation set in, with a slowly spreading lesion and peripheral superficial ulceration. When the patient was seen in December, 1951, the clinical picture agreed fully with lupus vulgaris and the histological picture revealed typical tuberculoid inflammation of the affected skin and regional lymph nodes. Tubercle bacilli were not demonstrable in cultures or on animal inoculation. The preceding BCG inoculation is believed to have been the etiological factor. The patient responded well to treatment with streptomycin, isoniazid, and PAS.

Effect of Intravenously Administered Solution of Honey on Dynamics of Circulation. K. Gotsch, E. Borkenstein and H. Clodi. Wien. Klin. Wchnschr. 68:647-651 (Aug. 17) 1956 (In German) [Vienna, Austria].

The effects of the intravenous administration of two preparations of solutions of honey on the dynamics of circulation were studied in six persons between the ages of 16 and 42 years with normal circulation. Three persons received intravenous injections of a 20% deproteinized solution of honey (Mel-P), which contained 812 mg. of dextrose, 834 mg. of fructose, and 343 mg. of saccharose and melezitose. After splitting by invertin the organism has at its disposal 878 mg. of dextrose and 1,129 mg. of fructose, i. e., a total amount of 2,007 mg. of sugar. The other three persons received intravenous injections of a preparation (Mel-S), which contained 20 mg. of vitamin B_1 and 0.125 mg. of strophantin in addition to the deproteinized solution of honey. Blood pressure, pulse rate, cardiac output, minute volume, elastic and peripheral total circulatory resistance, and cardiac performance were determined simultaneously with the consumption of oxygen. Recordings were made under conditions of basal metabolism.

The minute volume was somewhat reduced after the intravenous injection of the Mel-P preparation. The pulse rate did not show any significant change, and the reduction of the minute volume, therefore, was the result of a reduction of the cardiac output. Elastic and peripheral total circulatory resistance were not changed significantly. The blood pressure remained constant. These findings suggest a reduced energy stress on the myocardium. Observations on the persons receiving the Mel-S preparation showed that this circulation-sparing effect may be still further increased by the addition of strophantin to the honey. Simultaneous determinations of oxygen consumption showed that in some persons honey alone may cause a reduction of the consumption of oxygen in addition to a reduced energy stress on the myocardium. The acetylcholine content of the honey is considered responsible for the reduction in oxygen consumption, but this reduction also depends on the autonomous constitution of the person. The lowering of the cardiac performance by a reduced minute volume and the unchanged peripheral oxygen supply with improved oxygen utilization that characterize the change in the dynamics of the circulation after the administration of the honey-strophantin-vitamin B_1-mixture justify a therapeutic trial of this preparation.

Sternal Puncture: Its Indications and Limitations. B. M. Hurt and T. I. Robertson. M. J. Australia. 2:130-135 (July 28) 1956 [Sydney, Australia].

Studies were carried out to determine the part played by sternal puncture in the diagnosis and management of an unselected series of 272 patients in whom marrow was aspirated at a Sydney hospital during the years from 1945 to 1952. Thus there was adequate time for follow-up studies. The complete records and the progress of all these patients were studied, firm diagnoses were established, and the series was divided into three main groups and each of these into subgroups. There were 102 patients with anemias and related disorders, 85 with leukemias and reticuloses, and 85 with miscellaneous conditions including among others malignant disease, hepatic cirrhosis, chronic renal disease, bone disease, lymphadenopathies, abdominal tuberculosis, leprosy, and malaria. The diagnoses were made on the basis of the history, physical signs, laboratory investigations, and the progress of the disease. Reports on the pathology of excised nodes were available for many patients with lymphadenopathy. Autopsy was performed on 71 subjects, but, as many of the other patients are still living, the reaching of a diagnosis involved personal interpretation of clinical findings and is therefore subject to error. Doubtful cases were discarded from the series. In each instance the myelogram and the peripheral blood examination, made close to the time of the marrow puncture, were studied together.

Approximately 1 cc. of marrow fluid was aspirated and expelled directly onto slides, and thin films were spread. These were stained by the Jenner-Giemsa method and 500 cells were classified and counted. Other stains, such as peroxidase and Ziehl-Neelsen, were sometimes used. Bacteriological and cultural examinations were occasionally performed. Marrow samples were sometimes allowed to clot and were subsequently fixed, and sections were prepared to allow the general architecture and cellularity of the marrow to be studied; however, when this point was seriously under consideration trephine biopsy was employed. Information of greatest positive diagnostic value was obtained in patients with untreated pernicious anemia, multiple myeloma, the leukemias, and myelosclerosis, while confirmation of the diagnosis of hemolytic anemia and iron deficiency anemia was also provided. Sternal puncture was useful in excluding leukemia, multiple myeloma, myelosclerosis, and the diseases of lipoid storage when the blood count, physical signs, or results of other investigations indicated the presence of these diseases. Sternal puncture was useful in assessing the prognosis in patients with depression of the bone-marrow function, especially when neutropenia predominated. This investigation also revealed that examination of the marrow is of less importance than careful examination of the peripheral blood, and the marrow is usually found to be normal if the blood count is completely normal. Lymph-node biopsy is more informative than marrow biopsy in patients with both lymphadenopathy and a normal blood count. Nevertheless, although sternal puncture is rarely a short-cut to diagnosis, when it is properly used, confirmatory patterns and helpful negative results are often obtained.

Antidiuresis and Other Renal Responses to Piperoxan in Pheochromocytoma. A. C. Corcoran, H. P. Dustan and I. H. Page. Circulation 14:221-226 (Aug.) 1956 [New York].

Intravenous injections of 20 mg. of piperoxan hydrochloride were given to four patients with essential hypertension, to one patient with hypertension caused by acute glomerulonephritis, to four patients with functioning pheochromocytoma, and to one patient who had become normotensive after surgical removal of a pheochromocytoma. Piperoxan had a moderate renal vasodilatory effect and decreased the urine flow to about one-third of the pretreatment rate in the four patients with functioning pheochromocytoma. In contrast, it elicited slight renal vasoconstriction and usually increased the urine flow in the five patients with hypertension from causes other than pheochromocytoma and in the patient who had become normotensive after removal of a pheochromocytoma.

The antidiuretic effect of piperoxan in patients with functioning pheochromocytoma probably reflects inhibition of the renal vascular and tubular actions of norepinephrine and epinephrine and, insofar as it may correspond to the antidiuresis elicited by withdrawal of infusions of epinephrine and norepinephrine, may also involve posthypophyseal antidiuretic action. The diuretic effect of piperoxan in patients without pheochromocytoma is probably the result of a similar complex response. Since the antidiuretic effect of piperoxan in patients with pheochromocytoma has been larger proportionately than its effect on blood pressure, measurement of urine flow under standardized conditions is suggested as a simple, confirmatory guide in the diagnosis of pheochromocytoma.

Hepatitis and Diabetes. O. Günther. Ztschr. ges. inn. Med. 11:656-660 (July 15) 1956 (In German) [Leipzig, Germany].

Two factors deserve consideration in the explanation of the fact that jaundice due to hepatitis occurs more frequently in patients with diabetes mellitus than in persons without this disorder. First, patients with diabetes mellitus are more exposed to hematogenous infection because of the many blood sample withdrawals made even in diabetic patients who do not receive insulin injections. Furthermore, these patients are frequently hospitalized and during this time may receive one or several injections of insulin every day. (Daily insulin injections involve no danger if the patient uses his own equipment at home.) Second, there is the possibility that diabetic patients have a greater predisposition to infection in general and that their livers may be particularly susceptible to infection. The author investigated these factors on the basis of a statistical analysis of the records of 10,000 diabetic patients who were treated in diabetic departments between 1930 and 1954. This group included 755 patients (7.6%) who in the course of diabetes had one or several attacks of hepatitis. The incidence of hepatitis was highest during the first year after the diabetes became manifest. Furthermore, 693 (91.7%) of the 755 diabetic patients who contracted hepatitis received insulin injections, whereas the percentage of those requiring insulin injections was only 78.3% of the total. The author feels that these two facts show that diabetic patients are more likely to become infected with the virus of hepatitis by the hematogenous route. In view of the extreme heat resistance of the virus of hepatitis, more thorough sterilization of the injection instrumentarium was adopted at the author's clinic. Boiling the instruments used for insulin injection and for blood withdrawal for 20 minutes is regarded as inadequate, and hot-air sterilization at 160 C for 60 minutes or sterilization in the autoclave is demanded.

SURGERY

Structural Changes in the Heart Resulting from Cardiac Massage. G. H. Peddie, O. Creech Jr. and B. Halpert. Surgery 40:481-487 (Sept.) 1956 [St. Louis].

This report is concerned with the structural changes in the hearts of 14 patients on whom cardiac massage was performed and who subsequently died. Seven of the 14 patients died immediately of the cardiac arrest, one died at the end of six hours, and the remaining 6 died between 10 and 79 days later. Of these six patients, three died of cardiac arrest, while three regained consciousness but died later of their primary disease. Massage had been continued for up to 15 minutes in 10 of the patients, whereas in the remaining four it had been carried out for from one to five hours. The hearts removed at autopsy were fixed in formalin and were subsequently examined grossly and microscopically. As regards the immediate changes caused by cardiac massage, there was a traumatic, hemorrhagic pericardial effusion in the seven patients who died immediately and in the one who died after six hours. Other reports and the experience of these authors indicate that the effusion persists for at least 10 days and is followed by an outpouring of inflammatory cells and fibrin, so that the pericardial fluid becomes turbid with organization and fine fibrous adhesions. This reaction may progress to adhesive pericarditis.

There was evidence that the myocardial damage is in direct proportion to the duration of massage and is aggravated by previous myocardial changes. Epicardial hemorrhage and extravasations of erythrocytes between the myocardial fibers occur as a result of prolonged or too vigorous massage. Cardiac rupture may ensue if the traumatic myocardial changes occur in a heart already damaged by ischemia. This occurred in one of the 14 patients. There was evidence of some damage to the myocardium and pericardium in all the patients in whom massage lasted more than 15 minutes. Pericardial reaction, which was noted in nine patients, seemed to develop irrespective of the duration of massage and was not confined to patients whose pericardium had been opened. It is likely that manipulation of the heart and intracardiac injection of various agents are sufficient to produce pericarditis. No conclusions can be drawn from the use of the defibrillator in regard to cardiac damage, for in four of the five cases in which it was used there was also prolonged massage and the changes are attributed to this factor. Since cardiac massage is usually initiated hurriedly, manipulation tends to be vigorous, and when massage is continued beyond 15 minutes serious injury may follow. Experimental studies indicate that if performed carefully even prolonged cardiac massage will not damage the heart.

Causes of Death in One Thousand Operations for Congenital Heart Disease. W. J. Potts, W. O. McQuiston and T. G. Baffes. A. M. A. Arch. Surg. 73:508-516 (Sept.) 1956 [Chicago].

This report deals with operative and hospital deaths that occurred in 1,000 operations for congenital heart disease performed up to February, 1955, at the Children's Memorial Hospital in Chicago. The ages of the children ranged from 8 days to 16 years. There were 90 deaths and 89 postmortem examinations. The chief aim of the study was to learn which deaths were preventable. The postmortem examinations were often disappointing in that it was impossible to say which particular pathological change was the cause of death. In the group with cyanosis due to pulmonary stenosis remediable by surgery, the mortality year after year has remained near 9%. In the noncyanotic group the mortality has varied from zero in 347 operations for patent ductus arteriosus to 24% in patients with constricting vascular rings. The causes of death include errors due to oversight, poor judgment, and inexperience as well as to irremediable pathological conditions.

Patent Ductus Arteriosus in the Adult. H. Eliasch, K. Eriksson and L. Werkö. Acta med. scandinav. 155:135-156 (No. 2) 1956 (In English) [Stockholm, Sweden].

Thirteen women and four men between the ages of 18 and 47 years with patent ductus arteriosus were studied in an attempt to determine whether adult patients with patent ductus who are asymptomatic and those who have an excessive degree of pulmonary hypertension should be operated on. Eleven of the patients had normal pulmonary arterial pressure associated with high pulmonary blood flow; they were essentially free of symptoms. The remaining six patients had varying degrees of increased pulmonary arterial pressure and were more or less incapacitated. There was no correlation between age and pulmonary arterial pressure level. The oldest patient had normal pulmonary arterial pressure. Age also did not correlate with the size of the heart or the level of renal blood flow. On effort, pulmonary arterial pressure did not change in those patients who had normal pulmonary pressure when at rest. In patients with pulmonary hypertension, exercise generally caused a further rise in pulmonary arterial pressure. The systemic blood flow increased on effort in all patients. Whether this was caused by a reduced shunt or by an increase in the left ventricular output could not be assessed because of the difficulty of determining the pulmonary blood flow accurately. In patients with normal pulmonary pressure the renal blood flow was either normal or slightly reduced; in patients with pulmonary hypertension the renal blood flow was significantly decreased.

Five of the 11 patients with normal pulmonary arterial pressure were operated on. Surgical intervention and the immediate postoperative course were uneventful in four, but technical difficulty caused by a short and wide ductus was encountered in the course of the operation in one patient. The characteristic continuous murmur disappeared after the operation in all five patients, but it reappeared three weeks after the operation in the one whose operation was difficult. Follow-up catheterization revealed reopening of the ductus in this patient. All six patients with pulmonary hypertension were operated on. The operation and the immediate postoperative course were uneventful only in the oldest patient (aged 41 years) of this group in whom the pulmonary arterial pressure was restored to a normal level. One patient died during the surgical intervention from rupture of the pulmonary artery. Of the remaining four patients, one had failure of the right side of the heart and increased peripheral cyanosis three months after the operation; one had paraplegia, although the ductus was well closed and the size of the heart was markedly decreased after the operation; one patient was discharged with residual symptoms from arterial embolism; and one patient had a reactivation of rheumatic endomyocarditis but eventually recovered.

The importance of differentiating between so-called secondary and primary pulmonary hypertension in patients with preoperatively increased pulmonary arterial pressure is stressed. Two of the six patients with preoperatively increased pulmonary arterial pressure who had excessively increased pulmonary arterial pressure, normal pulmonary capillary venous pressure, and low pulmonary blood flow were therapeutic failures. The operative results were satisfactory in the other four patients with moderately increased preoperative pulmonary pressures, associated with increased pulmonary capillary venous pressure in two and with a low pulmonary capillary venous pressure and a high pulmonary blood flow in the two others. These four patients had so-called secondary pulmonary hypertension, and in patients of this type surgical intervention is indicated. Increased pulmonary blood flow alone is not responsible for the development of pulmonary hypertension. Anatomic narrowing and increased vascular tone in the peripheral pulmonary vessels may also be considered contributing factors.

omplete Anatomical Correction of the Tetralogy of Fallot Dects: Report of a Successful Surgical Case. C. W. Lillehei, M. Cohen, H. E. Warden and R. L. Varco. A. M. A. Arch. Surg. 73:526-531 (Sept.) 1956 [Chicago].

The authors report observations on a 17-month-old boy who was seriously ill with the tetralogy of Fallot defects and in whom complete anatomic restoration has been achieved. This is affirmed by his subsequent dramatic clinical improvement as well as by objective roentgenographic and catheterization studies carried out six months postoperatively. The technique of controlled cross circulation was utilized for the total bypass of the heart and lungs during the necessary interval of open cardiotomy. At that time the patient's ventricular septal defect was closed by the precise placement of silk stitches under direct vision. Next, the obstructing infundibular muscle was resected until an adequate outflow channel had been created. The boy's father served as the donor for the cross circulation.

Since March 26, 1954, the technique of controlled cross circulation for the total bypass of the heart and lungs has been used for reparative surgery under direct vision in 45 consecutive patients with a variety of cardiac lesions. From the knowledge and experience gained in these 45 direct-vision intracardiac operations with use of the cross circulation method, it has been possible to develop a simple, disposable, inexpensive, artificial oxygenator to replace the human donor, without sacrifice of the safety and effectiveness inherent in the donor method. Since then, with the use of this oxygenator and the same pump used for the cross circulation operations, 44 patients ranging in age from 4 months to 21 years have had their hearts and lungs totally bypassed for intervals of up to 50 minutes during direct-vision intracardiac correction of their defects. The patient reported is unique in that he is the initial patient to have the tetralogy of Fallot defects corrected with objective postoperative studies to corroborate his normal clinical appearance. Upon the basis of successes, as well as from the instructive failures, the authors have adopted the curative operation as the method of choice for all patients with the tetralogy of Fallot defects who are in need of surgical help at this time. For urgently ill patients in clinics where the curative operation may not be available as yet, the anastomotic operation without opening the pericardium is recommended only if they cannot be tided over by nonoperative management until the completely corrective operation becomes available to them.

Postoperative Wound Infection. R. A. Shooter, G. W. Taylor, G. Ellis and Sir James Paterson Ross. Surg. Gynec. & Obst. 103:257-262 (Sept.) 1956 [Chicago].

A rise in the incidence of infection in operative wounds at St. Bartholomew's Hospital in London led to an inquiry into its cause. The clinical facts suggested that infection was occurring in the operating room. A breach in surgical technique was not detected and it seemed that air-borne bacteria were responsible for the high infection rate of clean surgical wounds. Samples of the operating room air showed an abnormally high content of bacteria, and smoke testing of the ventilation showed that contaminated air from the surgical wards was being sucked into the room around the closed doors. The ventilation was modified so that the powerful input stream of pure air was directed across the operating table and out round the doors. This alteration greatly reduced the bacterial content of the air in the operating room, and the wound infection rate fell from 9 to 1%. The improvement was thought to be due to positive pressure ventilation of the operating theater and to avoidance of zones of still air over the operating table.

The Effect of Lowered Body Temperature on the Cerebral Hemodynamics and Metabolism of Man. H. H. Stone, C. Donnelly and A. S. Frobese. Surg. Gynec. & Obst. 103:313-317 (Sept.) 1956 [Chicago].

Studies performed upon animals indicate that hypothermia permits far longer periods of total cerebral vascular occlusion without sequelae than would be possible at normothermic levels. Since, however, the cerebral integration of animals is far less complex than that of man, Stone and associates studied the response of the human brain to acute reduction in body temperature. Measurements of cerebral hemodynamics and metabolism during periods of reduced body temperature were made on three surgical patients for whom hypothermia was employed as an anesthetic adjunct. In the absence of shivering, cerebral oxygen consumption was sharply reduced at body temperatures of 83 to 85 F (28 to 29 C). Within this temperature range, cardiac arrhythmias were infrequent. The effect of shivering upon the human cerebral response to hypothermia became evident particularly in the third patient. In spite of a reduction in body temperature to 82.6 F, cerebral metabolism increased 105% above the control value in the presence of shivering. The increase in cerebral oxygen consumption occurred despite a decreasing cerebral blood flow. This pattern of cerebral response to hypothermia with shivering closely resembles that observed after the intravenous administration of l-epinephrine, perhaps suggesting the importance of this drug in the mediation of the shivering reflex. These results demonstrate the danger of assuming that a reduction in cerebral metabolism always follows a reduction in body temperature. Total circulatory interruption at hypothermic levels in the presence of shivering for longer than three minutes could be extremely hazardous.

The cerebral blood flow decreased in all patients at hypothermic levels. Without the use of controlled respiration, a respiratory acidosis developed in each patient at hypothermic levels. Cerebral vascular resistance increased in each of the three patients at reduced body temperatures in spite of a consistent rise in carbon dioxide tension. Hemoconcentration and generalized vasoconstriction in response to hypothermia may have caused this increase. From the results of the studies on the first patient, which demonstrated a reduction in cerebral oxygen requirements to one-fourth the amount needed at normal body temperature, it might be concluded that, at a temperature of 83 F, cerebral ischemia could be safely tolerated for a period three times as long as the conventional three-minute interval, or a nine-minute period. This conclusion has been verified clinically in the human being by Swan and Bailey and their associates, but at body temperatures below 83 F. Until more is known about the degree of depression of the cerebral metabolism of man at specific hypothermic levels, it cannot be assumed that all patients will respond in like manner.

Evaluation of Pelvic Exenteration for Advanced Cancer of the Cervix. A. Brunschwig and W. Daniel. Surg. Gynec. & Obst. 103:337-341 (Sept.) 1956 [Chicago].

Since September, 1947, pelvic exenterations have been performed at Dr. Brunschwig's service in 441 patients with various forms of advanced pelvic cancer. This report is concerned with the 336 patients with carcinoma of the cervix in whom either complete or anterior pelvic exenteration was performed. Ninety-three or 27% of the patients had new cases, most of them being in either stage 3 or 4 (League of Nations classification). In the past two or three years more anterior exenterations have been performed in stage 2 cases in the presence of actual parametrial involvement and encroachment on the bladder or ureter. Three groups of patients had undergone definitive surgery with or without irradiation. One group had been treated by surgery alone, another had been subjected to conservative surgery after an attempted cure by irradiation, and in the third group conservative surgery had been followed by irradiation for recurrence. The decision to resort to exenteration was based on the extent of disease present and not on the type of previous treatment. In the earlier phases of this program, patients were not infrequently operated on for palliative purposes only. In these instances, diseased tissue was sometimes left behind. The results were poor. Now the tendency is not to attempt exenteration unless previous exploration at laparotomy indicates that all macroscopic evidence of disease can be removed.

Of 55 surgical deaths, 19 were due to shock, 7 to peritonitis, 6 to sepsis, 6 to uremia, 5 to intestinal fistula, 2 to pulmonary embolism, 2 to cerebral accident, and others to late hemorrhage, pneumonia, hepatitis, gastrointestinal obstruction, or unknown causes. Exenterations were initially undertaken for palliation only. No "cures" were expected at first. Palliation continues to be an objective, inasmuch as a 22.4% three-year survival rate was achieved. That a five-year survival can be offered is attested to by its 15% incidence in 111 minimally selected patients. Exenteration benefits patients with advanced pelvic cancer, especially those with recurrences after failure of radiation or more conservative forms of surgery.

Factors Influencing the Spread of Cancer. G. Crile Jr. Surg. Gynec. & Obst. 103:342-352 (Sept.) 1956 [Chicago].

The importance of the passage of time in the spread of cancer receives different emphasis in the two popular theories on the subject. The most widely supported theory is the concept that cancer starts as a localized disease, spreads to the regional lymph nodes, and with further passage of time spreads throughout the body. The second is the theory called by Ian MacDonald "biologic predeterminism," which holds that each cancer has certain biological characteristics that tend to remain more or less constant throughout its life. In this concept it is the type of tumor and the resistance of the host that largely determine the spread of cancer. Crile believes that it is impossible to prove or disprove that either of these concepts affords a complete explanation of the spread of cancer. In some cancers, such as those of the skin, the factor of time is not so important as is the type of the cancer and its biological behavior. A basal cell cancer of the skin rarely metastasizes to lymph nodes regardless of how long it is left untreated; a squamous cell cancer of the skin usually metastasizes only to lymph nodes and rarely metastasizes systemically; and, finally, a melanoma may metastasize systemically even before the primary tumor is noticeable. Cancers of the thyroid, like cancers of the skin, can also be separated into biological types. We know much less about cancers of the internal organs, and so it is easy to assume that it is the passage of time that causes a localized disease to become systemic. It is easy to assume that a localized cancer of the stomach is a young cancer that has not been present long enough to spread and that a diffusely metastasizing cancer is an old cancer that has been present long enough to allow it to metastasize. Yet in individual cases we know that primary cancers of the stomach that have given rise to systemic metastases may be so small that they are not recognizable on gross examination and that large cancers of the stomach, known to be present for several years, are often localized.

The author comments on the failure of early and radical treatment to alter the death rate from cancer, on the causes of this failure, and on the danger of the dissemination of cancer and the importance of the lymph-node barrier. Some types of localized cancer are well adapted to radical surgical attack. When cancers of the gastrointestinal tract are causing obstruction, infection, pain, or hemorrhage, prompt operation is mandatory and often lifesaving. Radical resection of pelvic organs for localized central recurrences of cancer of the cervix may eliminate all residual cancer, and, if the ureters are properly transplanted, the patient may enjoy a comfortable and useful life. But perhaps other cancers, such as infiltrating "leather-bottle" cancers of the stomach, when they are causing minimal symptoms and by their very type are not curable by resection, should be viewed in the same light as inflammatory cancers of the breast and operation should be avoided. A therapeutic trial of roentgen therapy to rule out lymphosarcoma might be preferable to the risk of dissemination that is incurred by exploration and biopsy. A policy of watching the development of this type of cancer and doing nothing so long as the symptoms are not severe might result in increased comfort and length of life. Perhaps in older people thorough electrocoagulation of selected low-lying cancers of the rectum may be perferable to combined abdominoperineal resections. Better results might be obtained if each cancer and each patient with cancer were dealt with as an individual problem. The author admits that these thoughts about cancer are not answers to the problems of its treatment but merely raise questions that should be considered before we generalize too much about cancer and place too much reliance on the classic philosophies and techniques. The greatest challenge is to recognize patients whose cancers are adapted to surgical cure and to avoid operating on those in whom intervention does nothing but harm.

The Etiology and Prevention of Volkmann's Ischemic Contracture. P. R. Lipscomb. Surg. Gynec. & Obst. 103:353-361 (Sept.) 1956 [Chicago].

The records in 92 cases of Volkmann's ischemic contracture seen at the Mayo Clinic from 1935 through 1954 were reviewed. Forty-four of the contractures developed after supracondylar fractures of the humerus, and 18 followed fractures of both bones of the forearm. Other causes were fractures of the shaft of the humerus (7 cases), severance of a major artery or arteries as the result of lacerations or gunshot wounds (7 cases), dislocation of the elbow (4 cases), and miscellaneous conditions (12 cases). The miscellaneous group was of special interest. The contractures in three of these patients developed from fractures about the elbow itself; two patients had fractures of the shaft of the radius alone, and one patient sustained multiple fractures of the humerus, both bones of the forearm, and the hand. Two patients had crushing and contusing injuries without fractures. Another patient sustained a wringer injury in which the skin was not broken but a large hematoma appeared in the antecubital fossa. Another patient was a true hemophiliac who bruised his arm six weeks before he came to the clinic; bleeding continued, and it was necessary to amputate the arm below the elbow. Another patient had undergone operation for congenital synostosis of the radius and ulna four months before examination at the clinic; the extremity had been immobilized in a cast in extension. The last patient in the miscellaneous group had been operated on for a traumatic arteriovenous fistula at the level of the elbow four months before coming to the clinic.

The author believes that in the light of knowledge available in 1935, 38 of the 92 contractures were preventable and that, with present-day information, 61 of the contractures would probably be preventable. Observations on the 92 patients and on another group of 10 patients who were seen from 1 to 72 hours after injury and on whom arteriectomy was performed because of irreparable arterial damage and impending Volkmann's contracture in some lead to the following conclusions: 1. Arterial injury with associated vascular spasm is the most important cause of Volkmann's ischemic contracture. 2. Major arterial obstruction is not so important in the production of the contracture as is the associated spasm of the collateral blood vessels. 3. Early and adequate treatment of acute vascular spasm is necessary, even though it means surgical exploration of the antecubital fossa and forearm and resection of the injured or thrombotic segment of the brachial, radial, or ulnar artery. 4. In compound or other fractures and severe crushing and contusing injuries of the forearm accompanied by severe edema, attempts should not be made to close the wound primarily; instead, extension of the original wounds and the use of relaxing incisions are often indicated.

Resection in Pulmonary Tuberculosis: Results and Follow-Up of 700 Cases. J. J. Hirdes and C. I. Stegerhoek. Dis. Chest. 30:277-288 (Sept.) 1956 [Chicago].

Seven hundred patients with pulmonary tuberculosis underwent lung resection at a sanatorium in Bilthoven, Holland, between October, 1949, and February, 1954. Pneumonectomies were performed on 127 patients, lobectomies on 385, segmental resections on 187, and bilateral resection on one. There were 364 male and 336 female patients between the ages of less than 10 and up to 70 years, most of whom were between the ages of 20 and 30 years. The patients were followed up to Feb. 1, 1955. At this time, 23 patients had died, a mortality rate of 3.3%. Death resulted from the operation in 12, 4 died of various complications during their sojourn in the sanatorium after the operation, and 7 died after discharge. Of 584 patients aged less than 40, 14 (2.4%) died. Nine (7.2%) of 116 patients over 40 years of age died. The risk of lung resection increases with age.

Postoperative tuberculous empyema occurred in nine patients and micrococcic (staphylococcic) empyema in four. Ten of the 13 patients with empyema had a bronchopleural fistula. With good surgical technique and proper evaluation of indications, or with good preliminary treatment, this complication has become rare. The great danger of development of resistant tubercle bacilli should always be kept in mind whenever antibiotics are used. If resistance has developed, then lung resection will be a dangerous operation. Not one case of tuberculous empyema was observed among the last 400 patients operated on. Empyema occurred particularly after resection of the upper lobe together with the apical segment of the lower lobe. In such cases there is danger that the remaining lung tissue is insufficient to fill the thoracic space. A space filled with air or exudate may result, and this predisposes to tuberculous empyema. Only when the middle and lower lobes have become enlarged as the result of preoperative contraction of the upper lobe can resection of the upper lobe with the apical segment of the lower lobe be considered. If reexpansion within six or eight weeks after the operation is incomplete, a thoracoplasty from the second rib up to and including the fifth rib may be considered.

In a follow-up of from two to five years, relapses occurred in 50 patients (7%). On Feb. 1, 1955, 92% of the patients operated on were in good condition and well. The best results were obtained in patients operated on for restricted, well-localized lesions of low activity, such as primary foci, tuberculous caseous foci, and tuberculomas. Results were less satisfactory in those with active, far-advanced forms of tuberculosis with cavitation.

P-Hydroxypropiophenone for Advanced Breast Cancer: A Preliminary Report. B. A. Stoll. M. J. Australia 2:181-183 (Aug. 4) 1956 [Sydney, Australia].

Although estrogens and androgens have the power to inhibit the growth of breast carcinoma, both these hormones may have unpleasant side-effects—nausea, vomiting, and uterine bleeding in the case of the former and virilization and fluid retention in the case of the latter. A search is therefore proceeding for a material that will induce pituitary gonadotropic hormone inhibition without the undesirable estrogenic effects. Lacassagne, in 1940, succeeded in modifying the chemical structure of synthetic estrogens so that they lost their peripheral estrogenic action. The new compound PHPP or POPP represents one-half of the diethylstilbestrol molecule. Its estrogenic activity is 1/10,000 to 1/1,000 of that of estrone or stilbestrol. Experimental work with p-hydroxypropiophenone (POPP) appeared to be at variance until the level of dosage was clarified, and reports on clinical trials of the compound likewise seemed contradictory. This report is concerned with 13 patients with advanced breast carcinoma, who were treated with POPP at a dose of from 1 to 10 gm. per day (0.02 to 0.2 gm. per 1 kilogram of body weight). Three levels of dosage were chosen, i.e., 1 gm., 5 gm., and 10 gm. per day. Only five of the patients were given 5 gm. or more per day, and only three of them received this dose for two months or more. Estrogens generally require six or eight weeks to become effective. Two of the three patients showed almost complete regression of nodular recurrences of breast carcinoma, and the third showed no change. No beneficial effects were obtained at doses of 1 gm. per day.

This is a preliminary report, as the number of cases is small. However, the principle involved is a most important one. The use of a pituitary-inhibiting compound without peripheral estrogenizing effect would have a wide field in the treatment of advanced breast carcinoma. Many patients complain of the nausea, vomiting, and uterine bleeding associated with estrogen administration in high dosage; more important, however, is the younger patient, to whom estrogens may not be given on account of the danger of exacerbation of the disease. The only hormone available for this group is testosterone, and the use of POPP avoids the virilization that ensues from the use of the male hormone.

Carcinoid Tumors of the Stomach. R. Lattes and C. Grossi. Cancer 9:698-711 (July-Aug.) 1956 [Philadelphia].

The authors described pathological findings in carcinoid tumors of the stomach in four men and one woman between the ages of 28 and 74 who underwent local excision or gastric resection at the surgical department of the Columbia-Presbyterian Medical Center in New York. Thirty-five additional cases were collected from the literature. The most interesting biological and clinical feature of these tumors is that, whenever surgical resection is possible, long-term clinical arrests can be expected, even in the presence of regional metastases. One of the five patients was alive and well 13 years after the discovery of retroperitoneal metastases and 12 years after resection of the primary tumor; one was living and well 13 years after subtotal gastrectomy and demonstration of metastases in the regional lymph nodes; and one was living and well 9 years after local excision. In the fourth patient, the carcinoid tumor was an incidental microscopic finding in a stomach resected for extensive carcinoma of the midgastric portion. The fifth patient had a large, fungating carcinoid tumor with regional lymph-node metastases for which he was operated on too recently to make evaluation possible. The gross and microscopic features of the tumor were notable. Grossly it resembled closely the common fungating adenocarcinoma. Microscopically, it was unusual in that, along with the classic histological structure of a carcinoid tumor, there were groups of mucus-secreting neoplastic glands The possible occurrence of glandular lumina in otherwise typical carcinoid tumors has been recognized by other workers and should be accepted as an occasional histological variant of these tumors. Three of the five patients had definite hyperchromic anemia.

The unique biological behavior of these tumors, with slow progression even after regional metastases have occurred, makes them a clinical as well as a pathological entity. In the evaluation of long-term results after surgery for gastic cancers, these neoplasms should always be segregated from the larger and more malignant group of the other metastasizing epithelial tumors of the stomach.

Spontaneous Passage of Necrotic Bowel. W. M. Cavies and J. D. Hicks. Australian & New Zealand J. Surg. 26:66-69 (Aug.) 1956 [Melbourne, Australia].

The patient was a 59-year-old woman on whom a cholecystectomy was performed. Seventeen days after the operation she passed 18 inches of necrotic colon after attacks of abdominal pain and diarrhea. At an operation a month later it appeared that the descending colon became necrotic and was sealed off by adhesions. To counteract this blockage a fistula between the sigmoid and the ileum had fortunately developed, allowing the excretion of intestinal contents. In spite of the breakdown of the upper abdominal wound as the result of the underlying hematoma, healing occurred and the patient went home with a colostomy after three months. At a third operation the descending colon was found to be reduced to a dense fibrous cord. In spite of dense adhesions, both in the splenic flexure and in the pelvis, the colon was reconstituted. Although the spontaneous separation of a segment of necrotic colon is rare, it has been observed before. The necrosis of the descending colon was probably due to thrombosis of the vascular supply, of the left colic artery for instance, rather than to an intussusception, the lack of a mesentery restricting any infolding of the colon. The retroperitoneal situation of the affected portion was probably responsible for the prevention of widespread peritonitis. As the damage extended into the sigmoid colon, an ileosigmoid fistula resulted. This fortuitous complication allowed the passage of intestinal contents, possibly more fluid than usual by virtue of the short-circuiting of the major portion of the colon. The closure of this fistula necessitated a transverse colostomy. The localized hematoma in the upper abdomen and the inflammatory collection in the pelvis were potent factors in delaying healing but the patient recovered steadily.

Major Vascular Injuries Incident to Intervertebral Disk Surgery. J. R. Mack. Am. Surgeon 22:752-763 (Aug.) 1956 [Baltimore].

Mack presents the histories of four patients in whom damage to the major vessels occurred in the course of intervertebral disk surgery. These four patients, treated by different teams in four different hospitals in the Cincinnati area, demonstrate a number of interesting points. The one patient in whom the surgeon was aware of the danger of this complication and recognized its occurrence was promptly and successfully treated by ligation of the left common iliac artery. Of the three patients in whom the operator was not aware of this danger and the injury was not recognized, two died of massive hemorrhage and one rapidly developed a large and disabling arteriovenous fistula. Observations on these patients and a review of the literature show that injury to the major vessels is an ever-present hazard during surgical interventions on intervertebral disks and can occur in the hands of the most competent and careful surgeons. The prone position of the patient on the operating table, with anteflexion of the spine, compresses the major vessels against the spine, thus putting them in an extremely vulnerable position and masking the injury when it does occur. The pituitary forceps is the instrument most commonly responsible for vascular damage. Awareness of the danger, although extremely important, is no assurance that the injury will not occur. The ease with which bleeding is controlled by means of Gelfoam or Oxycel is not a safe criterion as to the extent of the injury. It is usually not manifested by excessive bleeding, and so it must be recognized by careful postoperative observation.

Prompt recognition and treatment is the only method of reducing the disastrous mortality rate. The method of treatment may vary according to the site and extent of injury. Restoration of the continuity of the injured vessels by suture or arterial graft may at times be desirable but is by no means always essential; ligation alone may in some instances be simpler and safer. The common iliac artery, which is the most frequent site of injury, can be ligated with relative impunity because of its extensive collateral circulation. An arteriovenous aneurysm involving the common iliac artery can be treated by ligation of the artery above and below the fistula, leaving the small segment of artery attached to the vein because of the absence of branches in this portion of the artery. Immediate sympathectomy has been advocated, but is not essential for preservation of the viability of the extremity.

NEUROLOGY & PSYCHIATRY

Prevention of Paralysis in Poliomyelitis by Rest. T. Brehme. München. med. Wchnschr. 98:1064-1065 (Aug. 10) 1956 (In German) [Munich, Germany].

Paralytic symptoms are more frequent and more severe in poliomyelitis patients who continued their usual activities during the prodromal symptoms than in those who kept strict bed rest from the onset of the symptoms. Muscular exertion was observed to have a localizing influence on the subsequent development of paralysis affecting muscles that were subjected to special exertion. The chemical processes that take place within the ganglion cell while it is functionally active and also when it is invaded by a virus show why rest is essential during poliomyelitis and why neuromuscular exertion may have harmful effects. Paralysis is both more frequent and more severe in large muscles than in the smaller ones. This fact suggests that, the more active the ganglion cell, the more rapidly the virus affects its cellular metabolism and the more harmful the effect of the virus on the cell. The inactive or quiescent cell has a better prospect of being protected against the virus.

The effect of physical rest in bed can be augmented by the use of "hibernation" drugs, such as phenothiazine derivatives, particularly megaphen. These drugs proved helpful even in patients with imminent or beginning respiratory insufficiency. The author induced therapeutic sleep lasting for from three to five days by a combination of phenothiazine derivatives in 36 children and adults with bulbar-pontine poliomyelitis. This helped the patients over the critical period, and in 28 of them the use of the iron lung could be dispensed with. The favorable effect of this treatment is ascribed to the elimination of disturbing influences from the cortex and hypothalamus. The rest induced by the phenothiazine derivatives is not a therapeutic but rather a preventive measure. Only when these preventive measures are applied early enough can the destruction in the ganglion cells be avoided.

Habit-Forming Properties of Meprobamate (Miltown or Equanil). F. Lemere. A. M. A. Arch. Neurol. & Psychiat. 76:205-206 (Aug.) 1956 [Chicago].

Because meprobamate has been advertised as being non-habit-forming, the author wishes to modify a preliminary report in which he stated that meprobamate was not habit-forming. Further clinical experience has convinced him that this drug is habit-forming in some patients. Withdrawal symptoms are sometimes experienced. Patients occasionally describe a feeling of "nervousness" and "jitters" above their premedication level of tension, or a feeling of "let down," when they miss their usual dose of meprobamate. Six patients who had formerly been addicted to alcohol and barbiturates stopped taking meprobamate because, as they said, they felt they were "getting hooked" or addicted to the drug and "wanted no part of it." One patient who had been taking large doses of meprobamate had a convulsion (the only one he had ever had) 10 hours after discontinuing this medication.

The author observed 13 patients, among more than 600 for whom he prescribed meprobamate, in whom the drug had to be withdrawn because of excessive self-medication. The patient, or more frequently the relatives, will call up and say the patient is acting exactly as if he were drinking. The danger of driving a car while under the influence of excessive meprobamate medication is self-evident. Of the 13 patients, 10 were alcoholics who were abstemious at the time. It is especially urgent to watch for excessive self-medication and abuse when meprobamate is prescribed for alcoholics. The author does not wish to depreciate the clinical value of meprobamate, which he still regards as the most helpful and least harmful of all the drugs used for the relief of nervous and emotional tension.

Atypical and Minor Epileptic Seizures. J. Moossy. J. Louisiana M. Soc. 108:331-336 (Sept.) 1956 [New Orleans].

Patients who complain of bizarre alterations of consciousness, which may be brief or prolonged but are less dramatic than a generalized epileptic seizure, pose different diagnostic problems. If the patient has grand mal seizures in addition to these minor atypical or partial episodes, the physician usually grasps the relationship. However, if a patient has only minor seizures, their epileptic nature may not be promptly appreciated. The term "epileptic equivalents" has been used in the past for such phenomena, although clinicians since Hughlings-Jackson have realized that these attacks are epileptic, just as the generalized convulsion is, and the term "equivalent" has no significance. The clinical manifestations are so polymorphous and the structures possibly involved so complex (temporal lobe, insula, rhinencephalon, diencephalon) that descriptive or anatomic terminology is too cumbersome for routine clinical use. Among clinicians particularly interested in the disorder, clinical, anatomic, and electroencephalographic observations are often utilized in nomenclature; however, for most clinicians, recognition of these seizures and their varied etiologies is enough, and the term, minor epileptic seizures, is probably adequate.

The histories of five patients are presented. They were selected from a routine office and hospital neurological practice. Patients with similar histories also visit general practitioners and specialists. If the physician thinks that a given patient with minor or atypical seizures has epilepsy, some thought should be given to distinguishing grand mal, petit mal, and Jacksonian types from the type of seizures under consideration. This can be done by clinical analysis of the seizure patterns. This also gives clues to the areas of brain involved. With tentative localization, various etiological factors should be considered in the light of the past medical history, age of onset, and the results of a complete study of the patient. In two of the five illustrative cases no obvious cause of the seizures could be determined. Of the other three patients, one had had measles encephalomyelitis, one a malignant brain tumor, and one an old head injury. Treatment depends on the cause. In patients with focal lesions, such as tumors or vascular malformations, palliative or curative neurosurgical therapy is of great importance.

PEDIATRICS

Fetal Hepatitis. W. Kiaer. Ugesk. læger 118:865-868 (July 26) 1956 (In Danish) [Copenhagen, Denmark].

Infants with fetal hepatitis who are stillborn or die perinatally as a rule present no clinical signs of hepatic affection. Histologically, they show extraordinarily marked hepatic changes, which may find remarkably weak macroscopic expression. In those who survive the first few days symptoms set in that strongly suggest occlusion icterus; only in rare cases does the condition fail to simulate occlusion icterus. Some cases depend on transplacental transmission from mothers with latent infection, but other noxae, particularly blood incompatibility, may cause the hepatic changes. To these two groups of children with fetal hepatitis a third group, consisting of children who between the ages of 2 and 10 develop symptoms of chronic liver disease, may perhaps be added. They may conceivably represent cases of the disease so mild that they did not produce symptoms at birth but gradually passed over into a chronic hepatitis or cirrhosis, as can be seen in adults with acute virus hepatitis.

Fetal Hepatitis with Perinatal Death in Four Siblings. W. Kiaer and M. Olesen. Ugesk. læger 118:868-872 (July 26) 1956 (In Danish) [Copenhagen, Denmark].

A clinically well woman had given birth to three living children. Six later pregnancies were followed by perinatal death. None of the infants showed signs of hepatic affection. Microscopic examination of the liver in four cases revealed characteristic grave fetal hepatitis. A chronic latent virus infection in the mother is suggested in possible explanation of the fetal hepatitis. Serologic and histological examinations testified against erythroblastosis and syphillis. Fetal hepatitis will probably rarely be diagnosed in infants who die shortly after birth, and only autopsy can give certain diagnosis. The cause of death in the other two siblings was not established.

Purpura in Childhood: Observations in 187 Cases. S. D. Mills. J. Pediat. 49:306-315 (Sept.) 1956 [St. Louis].

One hundred eighty-seven infants and children less than 15 years old, more than half being 6 years of age or less, who had purpura of different types, were observed at the Mayo Clinic between 1945 and 1955. The distribution of patients according to sex varied little with age or with type of purpura. This sex distribution is contrary to that in adults, among whom women significantly outnumber men. One hundred five of the 187 patients had thrombopenic purpura and 82 had nonthrombopenic purpura. This difference in number of cases does not indicate the probable relative frequency of the two types of purpura in children as it is observed in general practice but rather reflects the increased number of patients referred for study because of difficult problems of bleeding and because they might require splenectomy. In 27 of the 105 patients with thrombopenic purpura, the condition was secondary to infection and in 78 it was idiopathic, i. e., there was no evident cause for the bleeding, such as drug reactions, vitamin K deficiency, or an underlying blood dyscrasia such as leukemia or aplastic anemia. Forty-nine of the 82 patients with nonthrombopenic purpura had the so-called anaphylactoid or allergic type, which is believed to be the result of capillary damage caused by drugs or by allergens that are usually bacterial in nature and result from recent infection. Seventeen patients had bleeding into the skin in the course of or after an infection. Ten of the remaining 16 patients with nonthrombopenic purpura had a vascular defect, and the purpura was not caused by any discernible allergic mechanism; the purpura was factitial in 2, orthostatic in one, congenital in one, and caused by a drug in one. None of these patients had a lack of platelets or a demonstrable defect of clotting.

In general, the prognosis for all types of purpura in children is good. Eleven of the 187 patients died, and all of them had thrombopenic purpura. Four of these deaths were in the idiopathic thrombopenic group; three of the four patients had acute purpura, one with generalized and fulminating hemorrhage and two with sudden, fatal cerebral hemorrhage; the fourth, a 14-year-old girl, died of uncontrolled menorrhagia. In the secondary, either thrombopenic or nonthrombopenic, types of purpura, the underlying condition should be sought out and treated. Eighteen children with the thrombopenic type of purpura and nine with the nonthrombopenic type were treated with steroid hormones for the control of bleeding, but the results were disappointing. Splenectomy was performed on 54 of the 78 patients who had idiopathic thrombocytopenic purpura. Fifty of the patients reported on were followed up for from 1 to 10 years; 37 were well and 8 were improved. Thus 90% of the traced patients were benefited. Two patients died in the postoperative period. These two fatalities represent a mortality rate of 4%, which does not seem excessive in view of the severity and chronicity of the illness in many patients. The risk of intracranial bleeding and of the continuance of purpura into adult life or into the menstrual age in girls should be considered in the determination of the treatment to be used.

Studies of Tocopherol Deficiency in Infants and Children: II. Plasma Tocopherol and Erythrocyte Hemolysis in Hydrogen Peroxide. H. M. Nitowsky, M. Cornblath and H. H. Gordon. A. M. A. J. Dis. Child. 92:164-174 (Aug.) 1956 [Chicago].

Simultaneous determinations of plasma tocopherol levels and lysis of red blood cells in hydrogen peroxide were made in 73 women on the obstetric wards of the Sinai Hospital in Baltimore within the first 24 hours of the postpartum period, in 15 normal adults, in 122 full-term and 14 premature unfed newborn infants, in 55 full-term infants fed cow's milk mixtures and 14 fed breast milk, in 28 thriving premature infants fed partially skimmed cow's milk mixtures, and in 16 infants and children with steatorrhea associated with cystic fibrosis of the pancreas or biliary atresia. The effect of tocopherol supplementation was determined in premature infants and in the infants and children with steatorrhea. The mean plasma tocopherol levels in the normal adults (0.75 mg. per 100 cc.) and in the postpartum mothers (1.07 to 1.56 mg. per 100 cc.) were markedly higher than those of the newborn infants (0.22 to 0.26 mg. per 100 cc.). Breast feeding was associated with a rise in mean tocopherol level to 0.72 mg. per 100 cc., and feeding of cow's milk mixtures, with a smaller but statistically significant rise to a mean level of 0.33 mg. per 100 cc. in infants of the average age of 46 days. Prematurely born infants fed partially skimmed cow's milk showed a decrease in plasma tocopherol levels from 0.26 mg. per 100 cc. in the first 10 days to 0.13 mg. per 100 cc. in infants over 30 days of age. Oral supplementation with small doses of tocopherol esters led to prompt rises in plasma tocopherol levels. Infants and children with cystic fibrosis of the pancreas or biliary atresia showed low plasma tocopherol levels, the average of 42 observations being only 0.15 mg. per 100 cc. Oral supplementation of tocopherol esters led regularly to a rise in plasma tocopherol levels of patients with cystic fibrosis. In patients with biliary atresia intravenous administration was necessary to produce consistent rises.

The hydrogen peroxide hemolysis test is a convenient method for separating patients with plasma tocopherol levels below and above 0.5 mg. per 100 cc., except in unfed newborn infants. Analysis of simultaneous determinations of plasma tocopherol levels and hydrogen peroxide hemolysis indicated that when the tocopherol level was above 0.5 mg. per 100 cc. appreciable hemolysis was rarely present. When tocopherol concentration was below 0.5 mg. per 100 cc. a statistically significant inverse correlation was found in young full-term and premature infants fed cow's milk mixtures and in infants and children with steatorrhea. No correlation was found in unfed newborn infants, virtually all of whom showed low plasma tocopherol levels, suggesting that factors in addition to plasma tocopherol are important in determining susceptibility to hydrogen peroxide of the erythrocytes of newborn infants.

Treatment of Measles Encephalitis with Corticotropin. E. Appelbaum and C. Abler. A. M. A. J. Dis. Child. 92:147-151 (Aug.) 1956 [Chicago].

Corticotropin (ACTH) was given to 17 consecutive children between the ages of 1½ and 10½ years with measles encephalitis. Fourteen of the patients had convulsions and 10 were in a state of coma. The daily dose of the hormone varied from 5 to 80 mg., and the total amount of corticotropin given to individual patients ranged in most of them from 100 to 320 mg. In 11 patients, remission of the fever and a decisive improvement in the mental state were observed within from one to four days. In the remaining six patients these changes became evident within from 6 to 13 days. None of the patients died. Fourteen of the patients were discharged from the hospital without any neurological or other detectable abnormalities. Three patients showed, at the time of their discharge, residual central nervous system stigmas, including impairment of vision, loss of speech, euphoria, and mental retardation. Follow-up studies carried out for from seven months to three years and nine months in 16 patients revealed that 15 of these escaped without residual symptoms. In one patient there were marked neurological sequelae. While this series is too small to permit definite conclusions, nevertheless the favorable results obtained in all but one patient suggest that corticotropin has a beneficent effect in measles encephalitis. Corticotropin should be given a clinical trial in measles and other forms of demyelinating encephalomyelitis. It would seem advisable to administer the drug before the time when the degenerative change of demyelinazation is apt to appear, i. e., before the third day of the disease.

Rupture of Liver in Infant, with Survival. E. Soto Pradera, J. S. Latour, C. Granda Leon and A. Carbonell Salazar. Rev. cubana pediat. 28:439-442 (July) 1956 (In Spanish) [Havana, Cuba].

Rupture of the liver is rare in newborn infants and still rarer in older infants. The rupture may result from trauma in the region of the liver or from disruption of a subcapsular hematoma, which is formed during birth, passes unobserved for a few days or a few weeks, and then ruptures. Eight cases reported in the literature were in newborn infants. The patients survived after suture of the liver. Of infants 2 to 6 months old, only one survived after a suture of the liver. The case reported by the author is the second of this type. An infant 4½ months old was hospitalized because of sudden appearance of intense paleness. There was no history of trauma. The number of erythrocytes was low but increased after a transfusion of 100 cc. of whole blood. The patient refused feeding but did not vomit. The roentgen examination of the abdomen showed opacity of the intra-abdominal shadows (a sign that has been recognized in the literature as showing intra-abdominal hemorrhage.) A diagnosis of intra-abdominal hemorrhage (probably due to rupture of the liver) was made, and an operation was performed. A transfusion of 500 cc. was given in the course of the operation. The peritoneum appeared dark blue, and 500 cc. of blood and coagula was eliminated. After aspiration of the blood and cleansing of the operative field, a rupture 1 in. long was detected on the lower surface of the liver. This was sutured. The operation ended without complications. The postoperative period was complicated by high fever and vomiting. The treatment consisted of blood transfusions and intravenous administration of fluids, penicillin, streptomycin, sulfamide, cortisone, vitamin K, and thromboplastin. The patient was discharged from the hospital three weeks after the operation in excellent condition and with an increased body weight. She was normal three months after the operation.

DERMATOLOGY

Hemangioendothelioma. R. L. Cormie. A. M. A. Arch. Dermat. 74:144-148 (Aug.) 1956 [Chicago].

Cormie reports on a patient with hemangioendothelioma because of the extreme rarity of this condition. The patient was a 52-year-old woman who, when first seen in September, 1954, complained of pea-sized to hazelnut-sized lumps of one month's duration. The lumps were noticed first on the outer aspect of the right upper arm and then in the area of the right trapezius and in each breast. Many similar subcutaneous nodules appeared on limbs and trunk in subsequent weeks, especially on the abdominal wall. The first lesions were skin-colored, but many became bluish-red or red, and some became firmly adherent to the overlying skin. They were occasionally painful and were slightly tender to touch. The patient complained of progressive weakness, which necessitated her confinement to bed from Oct. 15. Thereafter her condition steadily deteriorated; she died on Dec. 15, 1954. Autopsy was refused. At a biopsy one nodule had been removed from the breast and one from the right arm. Grossly they appeared to be hemorrhagic areas of rather "meaty" appearance. Microscopic studies revealed lesions consisting of areas of short, plump spindle cells closely packed together with a rich reticular fibrillar stroma. In places, blood-filled lumens were present, and around the margins of the lesion in the mammary fat there were plump endothelial-lined capillaries and spindle cells in a mass of hemorrhage. In some places the appearances were reminiscent of a cellular capillary angioma, but the more solid areas lacked the differentiation and were probably to be regarded as indicative of a malignant hemangioendothelioma. The tumors were too numerous for surgical excision when the patient was admitted. A test dose of 1,000 r at 140 kv. was delivered in one treatment to one lesion, with no appreciable effect. Diethylstilbestrol (stilbestrol) was also tried in increasing dosage up to 17 mg. per day, without benefit.

From 1925 to 1946 only four cases of hemangioendothelioma were seen and confirmed pathologically in the department of radiation therapy at Bellevue Hospital, New York, together with four other cases in all the other departments of the hospital during the same period, although many thousands of neoplasms were treated in that time. The consensus regarding treatment is that early surgical excision should be followed by irradiation, but opinions vary in regard to the efficacy of radiation therapy.

Histopathology of Cutaneous Lesions in Systemic Lupus Erythematosus. M. Prunieras and H. Montgomery. A. M. A. Arch. Dermat. 74:177-190 (Aug.) 1956 [Chicago].

The authors discuss the newer histopathological and histochemical procedures with regard to the cutaneous lesions of systemic lupus erythematosus. They studied 38 patients with systemic lupus erythematosus and 3 patients with chronic discoid lupus erythematosus. Sections were made from biopsy material fixed in a 10% neutral solution of formalin and embedded in paraffin. The slides were stained routinely by hematoxylin and eosin. The characteristic or diagnostic histological changes in the 38 patients with lupus erythematosus included follicular plugging with hyperkeratosis but without parakeratosis, liquefactive degeneration of the basal layer, and lymphocytic infiltration. Fibrinoid changes in vessels were not frequent (5 of 38 cases), and aggregates of karyorrhexic nuclei were even more infrequent (2 of 38 cases). Distinction between systemic and chronic forms of the disease was found to be almost impossible. The histological changes are related more to the age of the lesions than to the clinical type of the disease, early chronic discoid lupus erythematosus being morphologically indistinguishable from a recent cutaneous manifestation of the systemic form.

Changes in the basement membrane were found, with the aid of the periodic acid-Schiff reaction, to be constant and to be accompanied by an intense macrophagic activity of connective-tissue cells. Fibrinoid changes in the vessels were found less frequently than previous reports would indicate. A positive reaction to Sudan black B that was pyridine resistant was found in five cases; this is possibly related to early senile changes in the connective-tissue fibers. With the methyl green–pyronine stain, controlled by ribonuclease and perchloric acid extraction (modified Brachet test), intracellular bodies termed "red bodies" were found. These bodies represent depolymerization of desoxyribonucleic acid occurring in lymphocytic nuclei. These changes constitute frequent and nonspecific findings. They apparently occur also in the nuclei of connective-tissue cells as a possible early stage in the formation of "hematoxylin bodies." Use of staining with toluidine blue for metachromasia, controlled by use of hyaluronidase, acetylation, sulfation, and oxidation by chromic acid, disclosed preliminary experimental findings suggestive of a pathological modification of the synthesis of mucopolysaccaride by connective-tissue cells in lupus erythematosus.

Kurtin's Surgical Planing Procedure: A Review of Experiences with Special Reference to Post-Acne Scarring. A. A. Small. Canad. M. A. J. 75:279-284 (Aug. 15) 1956 [Toronto, Canada].

Kurtin's surgical planing procedure was practiced in 94 patients, most of whom were treated for postacne pitting. Other conditions were smallpox scarring of 30 years' duration, traumatic scars, tattoos, and even active acne covered with minute sebaceous cysts. Preoperative sedation consisted of 50 mg. of phenobarbital and 50 mg. of meperidine (Demerol) hydrochloride given hypodermically. Prechilling of the face was accomplished with ice packs containing 5% propylene glycol in water. The ice packs were kept in place for 20 minutes in order to remove the initial burning sensation. The field to be treated was delineated with benzalkonium chloride tincture or gentian violet. Ethyl chloride was sprayed on the area and simultaneously a current of air from a blower was directed on to the surface to accelerate the evaporation of the ethyl chloride and thus accelerate the freezing of the skin. The area was frozen so that it was firm to the palpating finger, and the planing was carried out with the Kurtin plastic planer, a small stainless-steel wire brush, disc-shaped and motor driven at 12,000 rpm under control of a foot rheostat. The revolving brush was held vertically against the surface of the skin and was moved fairly rapidly across the area to be planed, with long, firm, uniform strokes. The planing was carried on to the adjacent areas in a systematic manner, and a specific attempt was made to leave no unplaned areas. Usually both cheeks and the forehead were planed during one operation. Perforated Telfa dressings, which combine fabric and plastic materials, were applied to absorb the oozing and early bleeding. The patient was sent home and instructed to remove the dressing after 24 hours, to leave the face exposed to the air during the daytime, and to apply boric acid ointment dressings at bedtime for the first three or four days.

The amount of improvement from a single planing varied in the patients' opinions from 35 to 65%. In patients treated a second and third time, there was usually an additional improvement varying from 10 to 30%. Patients with a round chubby face and a good deal of subcutaneous tissue responded more satisfactorily to the treatment than those whose skin appeared to be closely adherent to the underlying bony structures. Full protection from strong sunlight and wind was essential for about a month after the crust came off, in order to avoid hyperesthesia and mottling of the affected areas. Some patients were subjected to the surgical planing procedure during a period when they had active cystic pustular lesions in some areas, especially along the sides of the neck. All such lesions healed uneventfully. The only precaution taken was the topical use of a mild antibiotic cream for 48 hours over the marsupialized area. The fairly sharp, well-defined, discrete, punched-out acne pit usually lent itself to good results, whereas the deep, poorly defined contracture type of pit that appeared to involve and exert traction on deeper layers of corium was usually much harder to eradicate.

OTOLARYNGOLOGY

Evolution of Surgical Technique in the Treatment of Carcinoma of the Larynx. C. L. Jackson and C. M. Norris. Laryngoscope 66: 1034-1040 (Aug.) 1956 [St. Louis].

Endoscopic excision is the most limited form of partial laryngectomy. Its technique has not undergone any remarkable changes, but the authors reemphasize the importance of the careful selection of cases. Laryngofissure (thyrotomy) is a term that should probably be restricted to the operation of simply splitting the larynx (or rather the thyroid cartilage) in order to gain access to the interior of the larynx for the purpose of removing a tumor and surrounding normal soft tissue. This operation is suitable for very early tumors of one vocal cord. The disrepute into which this operation fell during its early history was due to its misuse in the treatment of tumors that were too extensive and the piecemeal removal of tumor tissue followed by electrocoagulation. A better understanding of the indications for laryngofissure and improvements in technique resulted in its reinstatement. At the Chevalier Jackson clinic of Temple University Hospital the classic laryngofissure operation is still used in cancer involving the middle third of one vocal cord, but a modified form of the anterior commissure operation is employed when the lesion reaches the anterior commissure or crosses over to the opposite cord. In such cases the authors perform a partial laryngectomy with removal of varying amounts of underlying cartilage, an operation perhaps similar to the one Leroux-Robert called "anterior fronto-lateral laryngectomy." The authors also mention Alonso's technique of partial horizontal laryngectomy, which is suitable for limited supraglottic tumors.

Total laryngectomy, like laryngofissure, had a discouraging early history, with a high operative mortality and a high rate of recurrence. Gradually, with improved technique, the operative mortality rate has fallen to almost zero. A simple one-stage excision is now the usual procedure in uncomplicated cases, whereas only a few years ago several leading surgeons advocated a two-stage operation. Whether a vertical or transverse T-shaped or U-shaped incision is used and whether the larynx is removed from below upward or from above downward is a matter of individual preference, sometimes depending upon the location and extent of the tumor. The same may be said of the management of the hyoid bone. Some surgeons simply split it, others remove the body, and still others remove the entire bone. The management of the lymph nodes by "en bloc" dissection of the neck remains the most controversial point. Since only 4% of cordal tumors metastasize and only 10 to 15% of subglottic tumors do so, the surgeon may perhaps be justified in awaiting the appearance of nodes in these cases, but, since about 50% of supraglottic tumors metastasize, he should probably perform a simultaneous "neck dissection" when operating on these tumors, at least on the side of the lesion. When lesions are located anteriorly or bilaterally, it may be difficult to decide upon the side, and perhaps bilateral simultaneous "en bloc" dissection should be considered. The authors have performed more than 50 unilateral simultaneous "en bloc" dissections, but, since all these operations were performed within the past five years, it is not yet possible to give end-results. Summarizing the results in their other patients, they found 79.2% of five-year survivals following surgical treatment (328 of 414 patients). When all patients treated more than five years ago, by surgery and irradiation, are included, the survival rate is 69% (412 out of 593).

The Diagnosis and Treatment of Ménière's Disease. T. E. Walsh. A. M. A. Arch. Otolaryng. 64:118-128 (Aug.) 1956 [Chicago].

Ménière's disease is characterized by vertigo, tinnitus, and perceptive deafness. There is clinical evidence to support the theory that Ménière's disease is the result of vasomotor labyrinthine ischemia. A thorough history and physical examination are required to discover, if possible, allergic, endocrine, and psychosomatic factors that may have etiological significance. Inquiry usually elicits the fact that some hearing loss preceded the onset of vertiginous attacks. The audiometric findings are usually quite characteristic. The patient notices a very definite difference in pitch in the two ears when tested with tuning forks.

The objectives of therapy are to eliminate the vertiginous attacks or, at least, to diminish their intensity and frequency and, if possible, to reverse the hearing loss. Accepting the theory that vasomotor labyrinthine ischemia is due to vasospasm of the cochlear and vestibular vessels, vasodilator drugs have been used in an attempt to control the vertiginous attacks and to improve the hearing. Nicotinic acid in doses sufficient to cause flushing is given three or four times daily. This may be combined with methantheline (Banthine) or propantheline (Pro-Banthine). The author observed amelioration of the vertiginous attacks but no improvement in hearing with these agents. With knowledge of the remarkable effect of 2-acetylamino-1, 3, 4-thiadiazole-5-sulfonamide (Diamox) in glaucoma and in the hope that the secretion of endolymph might be inhibited, just as the secretion of aqueous matter from the ciliary body is inhibited, Walsh used Diamox clinically in a series of patients with Ménière's disease. In two patients there seemed to be a direct relation between the administration of Diamox and the lessening of the vertiginous attacks, but in none was there any appreciable change in the hearing. No one form of medical therapy is effective in all cases. Surgical destruction of the labyrinth gives relief in those cases in which one ear only is affected and should be considered after all medical management has failed.

THERAPEUTICS

Glutamic Acid in Hepatic Coma. N. W. Chaikin, M. S. Konigsberg and M. Schwimmer. Am. J. Gastroenterol. 26: 258-266 (Sept.) 1956 [New York].

Three women and two men between the ages of 42 and 66 years with cirrhosis of the liver and a 15-year-old girl with viral hepatitis became comatose and were treated with glutamic acid given intravenously and orally. An initial dose of 25 gm. of sodium glutamate was given intravenously in 500 cc. of 5% dextrose in distilled water. If the patient failed to regain consciousness within from four to six hours, the dose was repeated. As soon as the patient regained consciousness, the intravenous administration of sodium glutamate was discontinued and 15 mg. of glutamic acid was given twice daily, either orally or by intragastric drip. This was continued until the mental status of the patient was restored to normal. All the patients except the girl with viral hepatitis regained consciousness within 18 hours. The mental state cleared up and improved sufficiently to permit nourishment by mouth. Time was gained to treat the underlying disease more intensively. Administration of glutamic acid did not affect the course of the underlying disease or the results of the liver function tests. In two patients the blood ammonia and pyruvic acid levels were decreased. The exact mechanism by which glutamic acid restores consciousness is not entirely understood. Its beneficial effect may be (1) the result of its ability to unite with ammonia to form glutamine, which in turn is metabolized without the liberation of ammonia; or (2) its ability to combine with pyruvic acid and oxalacetic acid and so prevent ammonia formation.

Gonorrhea: Treatment with a Triple Penicillin Combination. H. R. Wherritt, H. E. Altheide and N. D. Duffett. Missouri Med. 53: 767-768 (Sept.) 1956 [St. Louis].

This study was designed to determine the effectiveness of two formulas, each containing a combination of three penicillin salts, in the treatment of gonorrhea. The original formula identified as Panbiotic provides 300,000 units of buffered potassium penicillin G, 300,000 units of procaine penicillin G, and 600,000 units of benzathine (N, N'-dibenzylethylenediamine) penicillin G per 2 ml. volume. The new formula is the same as the original except that procaine penicillin G has been replaced by the same number of units of dibenzylamine penicillin G. A total of 1,349 patients in whom the diagnosis of gonorrhea was based on a positive smear or culture were treated; 754 received 600,000 units of the new formula of Panbiotic and 595 received 600,000 units of the original Panbiotic. The new formula produced a 98.2% cure rate and the old formula a 98.1% cure rate. These cure rates compared faborably with rates obtained in the treatment of gonorrhea with other penicillin preparations. Only 14 patients showed positive laboratory findings that indicated failure of the treatment. No serious toxic manifestations were observed, and only two minor reactions occurred.

New Perorally Active Penicillin Preparation (Calcipen Leo). E. Henriksen, I. Larsen, E. J. Nielsen, K. Roholt and S. Tybring. Ugesk. læger 118:801-807 (July 12) 1956 (In Danish) [Copenhagen, Denmark].

Clinical investigations show Calcipen (the calcium salt of penicillin V) to be an effective peroral antibiotic in various infectious diseases due to bacteria sensitive to penicillin. Since December, 1955, it has been applied in Blegdam Hospital in 197 patients for whom penicillin was indicated, excluding patients with meningitis, unconscious patients, patients with difficulty in swallowing, and patients with grave gastrointestinal disturbances. The dosage for patients aged over 15 was one Calcipen tablet of 200 mg. every eighth hour daily for six days; for patients aged under 15, it was one half-tablet three times daily for six days. In patients with tonsillitis, scarlet fever, and pneumonia the results of Calcipen treatment equaled those attained by parenteral penicillin treatment. Whether penicillin perorally in the dosage applied is sufficient in treatment of acute suppurative otitis media is not yet certain. In about 7 or 8% of the cases treated there were side-effects, not of a serious kind, partly gastrointestinal, partly in the form of exanthems. As an antibiotic, Calcipen is equal to penicillin G preparation but differs from it in possessing the ability to produce higher serum concentrations.

Anticoagulant Treatment in Acute Coronary Occlusion with Special Reference to Indications. C. Holten. Acta med. scandinav. 135: 15-25 (No. 1) 1956 (In English) [Stockholm, Sweden].

The prognosis of ischemic heart disease, i. e., coronary occlusion, coronary thrombosis, and myocardial infarction, is more favorable now than it was 20 or 25 years ago, but the fact that the mortality rate is still high and the incidence apparently increasing makes the treatment of this condition a matter of outstanding importance. Thrombosis of one or more branches of the coronary arteries is an important but not the only cause of ischemic heart disease; sclerotic occlusion and thrombosis combined with sclerosis are also important, and together these causes account for more than 90% of the cases. The other 10% includes those without distinct infarction or anatomic occlusion and a smaller number in which there is typical infarction but no demonstrable occlusive process in the coronary vessels.

Modern treatment of coronary occlusion is based on the use of drugs that reduce the coagulability of the blood. Effective anticoagulant treatment will counteract the potentially dangerous tendency toward thrombosis found in patients with ischemic heart disease. Formation of the parietal thrombi in myocardial infarction not treated with anticoagulants begins about the fifth day after the onset of the acute attack; therefore, since the effect of the coumarin derivatives takes time to develop, treatment should be started as soon as possible. Heparin, which acts immediately when injected intravenously, may be used to overcome the delay caused by the slowness with which the coumarin derivatives act, but the need for repeated injections and other difficulties connected with the use of this substance in its usual form are distinctly disadvantageous. The author, therefore, in collaboration with the pharmacy of the Municipal Hospital at Aarhus, Denmark, prepared heparin in a sterile solution containing 1.25% carboxymethylcellulose. Each milliliter of this solution, known as Heparin Prolongatum, contains 10,000 international units of heparin. A dose of 2 ml. injected intramuscularly has been shown to prolong the clotting time to 28 or 29 minutes within two hours. The effect is still marked eight hours after a single injection. The solution, which is clear and of low viscosity, can easily be injected with use of a thin cannula. It has been used in 60 patients, 53 with coronary occlusion and 7 with phlebitis, since February, 1955. Altogether about 350 injections have been given; none of the patients had any tenderness at the site of the injections, and no hematomas have as yet appeared.

The first injection of 1.5 or 2 ml. is given as soon as the diagnosis is established, and the second is given eight hours later. Six injections in all are given, the second and subsequent doses being 1 or 1.5 ml. The dosage depends on the estimated weight of the patient. Tests carried out with samples of blood taken at various intervals after the start of the treatment and immediately before the next injection have shown that heparin prolongatum has a satisfactory effect on the clotting time. This application of heparin is an advance in anticoagulant therapy because it is safe and does not cause any discomfort to the patient, the injections can be given by a skilled nurse, and the prolongation of the clotting time is smoothly and evenly attained.

Anticoagulant treatment is indicated whenever ischemic heart disease is present and should be started as soon as the diagnosis has been established, because it is impossible to tell in advance whether the patient will prove to be a good risk or a poor risk. Adequate dosage and daily prothrombin controls are essential if the treatment is to be successful.

PATHOLOGY

Atherosclerosis and Occlusion of the Internal Carotid Artery. K. C. Samuel. J. Path. & Bact. 71:391-401 (April) 1956 [Edinburgh, Scotland].

Both internal carotid arteries were removed in their entirety from the bodies of 82 persons aged, with one exception, from 45 to 91 years. They were studied by the method of frozen sections. Seventy-four subjects revealed atherosclerosis of some degree, including 15 cases of severe atheroma. Severe grades of atherosclerosis were seen twice as often in men as in women. Complete occlusion of one carotid artery was seen in five cases; the internal carotid in four and the common carotid artery in one. Two of these occlusions were due to recent thrombus, one to an organizing thrombus, and two to atherosclerosis alone. Thrombosis in each case had occurred on the left side.

Atherosclerosis was the only arterial disease observed. Thrombosis appeared to be a complication of it. Three cases of severe atherosclerosis showed foreign-body giant-cell reaction around cholesterol crystals. It was thought that two different forms of atherosclerosis could be seen: fatty changes in mural thrombi and pure lipoid deposits by cholesterophages. The site of most severe involvement was found to be the sinus portion of the artery. Next in order of frequency were the cavernous, cerebral, petrous, and cervical portions. In one case the artery was occluded in the petrous portion. Brain lesions were variable but were present in most cases of severe atherosclerosis. They probably depend on the patency of the opposite carotid artery, and on the collateral circulation through the circle of Willis. Their symptomatology was varied. Mental confusion, dizziness, dementia, and hemiplegia were especially noted. Symptoms were absent in one case in spite of complete occlusion of one internal carotid artery. Occlusion or narrowing of the internal carotid arteries from atherosclerosis should be considered among the causes of mental or neurological symptoms in elderly persons.

PHYSIOLOGY

Cholinergic Innervation of the Digital Arteriovenous Anastomoses of Human Skin: A Histochemical Localization of Cholinesterase. H. J. Hurley Jr. and H. Mescon. J. Appl. Physiol. 9: 82-84 (July) 1956 [Washington, D. C.].

Six-millimeter punch biopsies were taken from the skin of the volar pads of the great toes of five healthy, white, male volunteers (22 to 25 years of age) after block anesthesia of the digit with a 1% procaine solution. The technique of Koelle, using the latest modifications described for the localization of specific and nonspecific cholinesterase, was then employed on fresh frozen sections (10-μ thickness) of these specimens. Specific cholinesterase was found in many nerve fibers about the specialized arteriovenous anastomoses of digital skin and about the secretory tubules of eccrine sweat glands. The enzyme was absent about other cutanous vessels and the ducts of the sweat glands. No significant concentrations of nonspecific cholinesterase were detected about any of these structures. The presence of specific cholinesterase about the digital arteriovenous anastomoses indicates that these vessels possess a cholinergic innervation. On the basis of cited pharmacological evidence, it is suggested that this innervation is vasodilatory.

Effect of Amino Acid and Glucose Ingestion on Arteriovenous Blood Sugar and Appetite. S. M. Mellinkoff, M. Frankland and M. Greipel. J. Appl. Physiol. 9: 85-87 (July) 1956 [Washington, D. C.].

When healthy persons ingest whole or hydrolyzed protein, appetite diminishes as the serum amino acid concentration rises and vice versa. The same inverse relationship appears after the infusion of amino acids despite the fact that both infusion and ingestion of amino acids cause the blood sugar level to fall. Thus, appetite is depressed when the blood sugar level is low, and a recrudescence of appetite is accompanied by a rising blood sugar level. Mayer suggested that the metabolic regulation of the appetite might be explained by nervous centers that are responsive to changes in the arteriovenous (a-v) differences in blood sugar. The effect of amino acid ingestion upon the arteriovenous blood sugar difference was investigated in 16 normal volunteers. After the usual nocturnal fast, they drank 250 cc. of 10% amino acids. Blood specimens were obtained from the antecubital vein and from one of the finger tips in the fasting state, 30 minutes after the test meal, and at hourly intervals after the test meal for a period of four hours. As a means of comparison, the procedure described above was followed in 10 normal volunteers, but a solution of glucose was used as the test meal instead of amino acids. The following were serially estimated: (a) serum amino acid nitrogen, (b) venous and capillary blood sugar, and (c) desire for food.

After the ingestion of amino acids, the blood amino acid concentration and the arteriovenous blood sugar difference increased, while the venous blood sugar level and the appetite fell. After the ingestion of glucose, appetite varied inversely with the arteriovenous blood sugar difference, but there was no correlation between appetite and the serum amino acid concentration. There was a considerable range in the fasting arteriovenous sugar difference in these healthy persons. Thus an arteriovenous sugar difference of 8 mg. per 100 cc. one hour after the test meal in one individual represented an increase in the arteriovenous sugar difference of 8 mg. per 100 cc., while in another individual the same one-hour value represented an insignificant increase of 2 mg. per 100 cc. Nothing in these simple experiments can be construed as proof or disproof of Mayer's arteriovenous sugar hypothesis, but the data are not inconsistent with this hypothesis. The fact that the venous blood sugar level was generally lowest when the arteriovenous sugar difference was greatest suggests that one mechanism for depressing the venous blood sugar level after ingestion of amino acids is uptake of glucose by the muscles. That this mechanism is probably not the only one operative is suggested by the fact that in some individuals a significant fall in the venous blood sugar level occurred without any real change in the arteriovenous sugar difference. In the latter circumstance, presumably the glucose was taken up by the liver.

Studies on the Physiology of Hunger: I. The Effect of Intravenous Administration of Glucose on Gastric Hunger Contractions in Man. A. J. Stunkard and H. G. Wolff. J. Clin. Invest. 35: 954-963 (Sept.) 1956 [New York].

The observation that the intravenous administration of glucose could abolish gastric hunger contractions in fasting dogs led Bulatao and Carlson to postulate that lack of availability of carbohydrates for utilization is an important factor in the genesis of the gastric hunger contractions. Recently this problem was reopened by Mayer's "glucostatic" theory of the regulation of food intake, which ascribes hunger to a depletion of the carbohydrate stores of the body and satiety to the replenishment of these stores. According to this theory, the status of the carbohydrate stores is signalled to the hypothalamic food-regulatory centers by the rate at which glucose is utilized. To obtain more information on the effects of glucose on gastric hunger contraction the authors investigated the capillary-venous glucose differences in fasting subjects and after the injection of glucose.

They found that intravenous administration of 50 ml. of a 50% solution of glucose was followed within five minutes by the cessation of gastric hunger contractions in 19 of 40 experiments on a group of diabetic and nondiabetic human subjects. At 10 and 20 minutes after injection, the peripheral capillary-venous glucose differences in the group of 19 subjects in whom contractions were inhibited were significantly higher than those of the subjects in whom contractions persisted. In 14 of the 19 experiments in which contractions were inhibited, they returned at an average of 47 minutes after the injection. The capillary-venous glucose differences at 10 and 20 minutes after injection were usually higher than those at the time contractions returned, but this difference was not significant at the 5% level. The capillary-venous glucose differences in the 5 experiments in which contractions remained inhibited were significantly higher than those in the 14 experiments in which they returned. These findings support the view that metabolic events accompanying increased peripheral removal of glucose have an inhibiting effect on gastric hunger contractions. Events associated with decreased removal, on the other hand, are not a sufficient stimulus for the production of gastric hunger contractions, although they appear to be a necessary condition.

BOOK REVIEWS

Treatment of Heart Disease: A Clinical Physiologic Approach. By Harry Gross, M.D., F.A.C.P., Attending Physician, Montefiore Hospital, and Abraham Jezer, M.D., Attending Physician, Montefiore Hospital, New York. Cloth. $13. Pp. 549, with 91 illustrations. W. B. Saunders Company, 218 W. Washington Sq., Philadelphia 5; 7 Grape St., Shaftesbury Ave., London, W.C.2, England, 1956.

According to the authors, this book was added to the numerous recent books on heart disease as a "presentation of therapy in heart disease based upon sound physiological principles." Actually, the volume contains a great deal of information regarding symptomatology and diagnosis of the various forms of heart disease in addition to the discussion of therapy. The book is divided into seven parts. The first deals with the general aspects of pathological physiology of the circulation and with the action and clinical use of digitalis and quinidine sulfate; the subsequent sections deal with the pathogenesis, diagnosis, and management of hypertensive and arteriosclerotic heart disease, heart disease secondary to inflammation, congenital heart disease, surgery and pregnancy in heart disease, heart disease secondary to metabolic disorders, and the psychosomatic aspects and rehabilitation of patients with heart disease. A well-chosen list of references is included after each chapter, and at the end there is a useful appendix containing diets, recipes, and tables of the sodium and potassium contents of foods.

By and large, indications to medical and surgical therapy and details of the therapeutic management are well presented. It is to be hoped that in future editions the chapter on treatment of acute pericarditis will be expanded and will include treatment of tuberculous pericarditis. Occasional inconsistencies should be eliminated; for example, in the chapter on paroxysmal tachycardia it is first stated—and rightly so—that variations of the first heart sound do not permit one to differentiate between supraventricular and ventricular tachycardia, but later the same phenomenon is referred to for the differentiation of the two types of paroxysmal tachycardia. Slowing of the heart rate by quinidine in sinus tachycardia is mentioned and explained as a vagal effect on the sinus code. Actually, the vagal effect of quinidine consists in an atropine-like action. Of the drugs to be used to abolish premature beats, digitalis is listed first and quinidine second. Procaineamide hydrochloride is not mentioned at all. This order of efficacy can be questioned. Exception can be taken to the statement that electrically induced pulsus alternans is "one of the few pathognomonic signs of digitalis poisoning." It is regrettable that a number of the illustrations show some of the electrocardiograms upside down, as in figures 14, 33, 46, and 48, or mislabeled, as in figure 40. In spite of such minor flaws the book can be recommended both to the general practitioner and to the internist as a competent, up-to-date textbook on cardiac therapy written by two authors familiar with the literature, guided by an extensive experience of their own, and exhibiting a rather essential attribute of a good therapist: common sense.

The Doctor in Personal Injury Cases. By Harold A. Liebenson. Cloth. $4. Pp. 123. Year Book Publishers, Inc., 200 E. Illinois St., Chicago 11, 1956.

With the ever-increasing number of claims and suits requiring written reports or testimony from physicians, it is important for attorneys to take the time and effort to help the medical profession understand the proper form and the significance of the evidence or testimony they are called on to present. This book is a conscientious effort on the part of an experienced trial attorney to pass on his experiences and suggestions to physicians and attorneys. The book is a short, concise, simply worded and welcome addition to medicolegal literature.

The glossary of legal terms is short, yet sufficient to meet the needs of most physicians. The description of the conduct of a trial, the legal rules governing the admissability of opinion evidence, and the discussion of the purpose and form of hypothetical questions should be particularly helpful and informative to the medical profession. In all probability, however, the most significant contribution that the book provides is in connection with medical reports. Despite the frequent demands on physicians for such reports, there is a surprising lack of understanding as to their proper form and their tremendous importance in the equitable settlement of claims. If the suggestions presented concerning the preparation of medical reports and the proper demeanor of a medical witness in court would be read and followed, the time, patience, and reputation of many physicians would be saved. In addition, and most important, many cases could be settled equitably prior to trial, and those that did go to trial would be decided on full, complete, and unbiased medical facts.

Occasionally the author has mistakenly portrayed the physician or medical witness as an advocate rather than as an unbiased reporter of facts in the personal injury case. On page 5 he says: "Once the doctor realizes and understands his importance in these cases, half the battle of winning personal injury cases is over." What he means is that half the battle of obtaining justice is over—a result that does not always mean "winning" a personal injury case. Again, on page 6, in discussing the causal connection between the alleged injury and the accident, he says: "At trial the doctor must prove this point." Actually, the testimony of the physician may either prove or disprove this point. Any burden of proof that exists is on the plaintiff and his attorney—not the physician. This book has nine chapters. It should have stopped at eight. It is inevitable that any attempt to discuss malpractice, privileged communications, workmen's compensation, subpoena, and *subpoena duces tecum* in five and one-half pages will result in inaccuracies, misstatements, and false impressions. Chapter 9 is no exception. The rest of the book, however, is well written and informative, and, as stated, in the foreword, "is a worthwhile addition to the physician's and lawyer's library."

Otolaryngology. Volumes 1-5; General Index. Edited by George Morrison Coates, A.B., M.D., Consulting Otolaryngologist, Hospital and Graduate Hospital of University of Pennsylvania, Harry P. Schenck, B.S., M.D., Professor and Head of Department of Otolaryngology, University of Pennsylvania School of Medicine, and M. Valentine Miller, B.S., M.D., Sc.D., Professor of Clinical Otolaryngology, Graduate School of Medicine, University of Pennsylvania, Philadelphia. Cloth, loose-leaf. $105 [which includes service of new pages and Consulting Bureau for one year] .Various pagination, with illustrations. W. F. Prior Company, Inc., P. O. Box 350, Hagerstown, Md., 1956.

Attractive in appearance, beautifully illustrated, and smoothly edited, this large work consists of the contributions of 118 distinguished specialists in fields relating to the ear, nose, and throat.

Volume 1 deals especially with the anatomy, physiology, anomalies, and diseases of the external ear; with otitis media; and with tinnitus, vertigo, and deafness. Volume 2 continues with otosclerosis and fenestration, mastoiditis and mastoidectomy, audiology and the rehabilitation of the deaf, and the treatment of certain tumors and infections. Volume 3 deals mainly with the nose and the accessory sinuses, their diseases (including allergies), and their surgical and radiological treatment. Volume 4 is devoted mainly to the mouth, pharynx, and larynx and contains valuable contributions on bronchoscopy. Volume 5 contains chapters on the esophagus, on the removal of foreign bodies from the respiratory and upper gastrointestinal tract, on speech difficulties and the relearning of speech after laryngectomy, and on the other sciences and specialties relating to otolaryngology. The chapter on pharmacology is particularly valuable because of the concreteness of the information, especially in regard to dosage. While the contributions vary somewhat in quality, most are critical and up-to-date, and some deserve to become classics. An excellent system of numbering the pages makes it easy to locate the passages referred to by the index. This is vital not only because of the loose-leaf plan of the volumes but also because of the multiple authorship, which has evidently made it hard to follow a completely logical plan in arranging successive chapters. The index still leaves much to be desired, however. It does not

These book reviews have been prepared by competent authorities but do not represent the opinions of any medical or other organization unless specifically so stated.

enable one to locate, for instance, the important material on cholesteatoma given in volume 1 (chapter 10, page 78) or the material and illustration on actinomycosis found in volume 2 (chapter 26, page 9). This defect can easily be remedied in a book that is intended to be, and deserves to be, a continuing project.

Cardiac Pressures and Pulses: A Manual of Right and Left Heart Catheterization. By Aldo A. Luisada, M.D., Associate Professor of Medicine, Chicago Medical School, and Chi Kong Liu, M.D., Instructor of Medicine, Chicago Medical School, Chicago. Cloth. $6. Pp. 116, with 51 illustrations. Grune & Stratton, Inc., 381 Fourth Ave., New York 16; 99 Great Russell St., London, W.C.1, England, 1956.

Since cardiac catheterization has become a well-recognized diagnostic procedure, such a book as this, describing the techniques in detail, is most welcome. It was only a little more than a decade ago that Cournand showed that catheterization of the right side of the heart could be safely performed in man. Since then, many improvements in recording instruments and in the technique itself have been made. Recently, relatively safe techniques for catheterization of the left side of the heart have been made available. The procedures are all carefully described in this book. The authors, who have had extensive experience with the techniques, emphasize the necessity for a good, well-trained team of from four to eight persons in order to get the necessary information from the tests. One person passes the catheter, another takes care of the recording instruments, another handles the x-ray apparatus, and another collects the blood samples. Occasionally additional personnel, such as a nurse, an anesthetist, a surgeon, or an additional technician, may be necessary. The procedures are described in detail, step by step, and attention is called to faults in technique that might increase the risk to the patient or give unsatisfactory results. Much space is allotted to artefacts and how they may be prevented. This section is important, because the presence of artefacts in the records obtained could lead to faulty and inaccurate interpretations. The book is well illustrated. It is recommended as an excellent reference book not only for the physician who actually does cardiac catheterization but also for those who interpret the data obtained from such studies. It is a book that every cardiologist should have in his library for ready reference.

Hutchison's Food and the Principles of Dietetics. Revised by V. H. Mottram, M.A., and George Graham, M.A., M.D., F.R.C.P., Consulting Physician to St. Bartholomew's Hospital, London, England. Eleventh edition. Cloth. $8.25. Pp. 630, with 17 illustrations. Williams & Wilkins Company, Mount Royal and Guilford Aves., Baltimore 2; Edward Arnold & Co., 41-43 Maddox St., London, W.1, England, 1956.

Those who have a special interest in foods, diet, and nutrition will find interesting reading in this book, but those who want a concise reference on the subject should consult the standard works written by investigators in the United States. No objection is taken to the reliability or authoritativeness of the book, but, as it was written for use in England, the physician and nutritionist in the United States is likely to find it confusing.

Anatomical Atlas of the Human Brain and Spinal Cord. By Mieczysław Stelmasiak, M.D., Professor of Human Anatomy, Medical Academy, Lublin. Translated by F. Stański, M.D., from second Polish edition. Cloth. Pp. 227, with 241 plates. Polish State Medical Publishers, Principal Medical Library, 22 Chocimska, Warsaw, Poland, 1956.

This atlas is an English translation prepared from the second Polish edition, which appeared in 1953. Russian and German translations are said to be in preparation. Professor Stelmasiak of the Medical Academy of Lublin has used the *Nomina Anatomica* adopted in 1955 by the sixth International Anatomical Congress at Paris. The book is a true atlas, without text except for figure legends. It consists of diagrams (a few in color), drawings, photographs, and charts of neural pathways. Diagrams are well reproduced but oversimplified. Photographs of transverse and sagittal sections of the brain stem and cerebellum, and transverse, sagittal, and horizontal sections of the cerebrum, form the greater part of the atlas. These illustrations are poorly reproduced and are lacking in contrast, definition, and detail. It is unfortunate that black backgrounds were used throughout for these photographs. Photographs of the brain are well reproduced and clearly labeled. Most of the drawings appeared idealized and unreal. A section of the atlas devoted to craniocerebral topography contains photographs of the head sectioned in various planes. The value of such photographs is questionable. The size and probably the cost of the atlas could have been reduced by better use of space. About 100 of the 218 pages contain illustrations occupying only half of the page. This atlas is not equal in any respect to Riley's "Atlas of the Basal Ganglia, Brain Stem and Spinal Cord," which is so highly regarded by most students of the nervous system. Most of the standard neuroanatomic textbooks used by students in the United States provide better and more detailed illustrations of the nervous system.

Muscle Testing: Techniques of Manual Examination. By Lucille Daniels, M.A., Associate Professor and Director of Physical Therapy, Department of Allied Medical Sciences, School of Medicine, Stanford University, San Francisco, Marian Williams, Ph.D., Assistant Professor of Physical Therapy, Stanford University, and Catherine Worthingham, Ph.D., Director of Professional Education, National Foundation for Infantile Paralysis, Inc. Second edition. Paper. $4. Pp. 176, with format and test illustrations by Harold Black; anatomic drawings by Lorene Sigal. W. B. Saunders Company, 218 W. Washington Sq., Philadelphia 5; 7 Grape St., Shaftesbury Ave., London, W.C.2, England, 1956.

This book offers a wealth of accurate anatomic and kinesiological information, in the form of text and line-drawings, for use in testing and recording the status of individual muscles in patients with various forms of neuromuscular disability. The material is often rendered unclear by the use of a telegraphic style, but the illustrations are excellent. Commendable effort has been put into a comparative study of other proposed methods of grading manual muscle tests, but much work along this line remains to be done. Bovard and Cozens have shown that a given mass of data can generally be scored in many ways but that the various ways can be compared systematically as to their dependability by computing reliability indexes from test-retest data. The choice of the best possible method of scoring becomes extremely important in any situation that involves questions of employability or compensation. It is hoped that the authors will continue their good work in this direction. The book lacks an index, but it has a good bibliography.

Understanding Human Behavior. By James L. McCartney, M.D., F.A.C.P. Cloth. $3.50. Pp. 258, with 12 illustrations. Vantage Press, Inc., 120 W. 31st St., New York 1, 1956.

This book is clearly written and presents in 10 well-organized chapters adequate information to the intelligent layman about the current neuropsychiatric theories and practices. Its lucid style, unbiased approach, and hopeful outlook into "a philosophy of living" make it a worthwhile addition to the available literature. In dealing with normal and abnormal sexual behavior, the author's long psychiatric experience leads to thoughtful evaluations. The chapter on diagnosis aptly describes the many psychic reactions and disorders, but it is weighed down by a long list of the standard nomenclature of the American Psychiatric Association and too much emphasis on electroencephalographic studies. This results in scant information about important psychometric and projective test methods. The chapters about origin of frustration, origin of guilt, psychotherapy, and physical treatments make fine introductory reading for medical students and nurses. A glossary and index complete this useful book.

Poliomyelitis. By W. Ritchie Russell, C.B.E., M.D., D.Sc., Director, Department of Neurology, United Oxford Hospitals, Oxford, England. Second edition. Cloth. $3. Pp. 147, with 40 illustrations. Williams & Wilkins Company, Mount Royal and Guilford Aves., Baltimore 2; Edward Arnold & Co., 41-43 Maddox St., London, W.1, England, 1956.

This monograph constitutes an extensive review of the literature. It is well arranged, with a good table of contents for ready reference, and should be of value to clinicians who have occasion to see patients for diagnosis or treatment. The discussion on the treatment of respiratory paralysis in spinal cases perhaps gives undue emphasis to the European's conception of respiratory devices, namely, the use of positive pressure; however, due recognition is given to American methods of treatment. In fact, the advantages and disadvantages of both concepts of treatment are presented quite fairly. In the final chapter, on future prospects, the continued reluctance on the part of the British to recognize the value of inactivated virus vaccine is apparent; and the summary indicates an undue reliance on the early availability of a live virus vaccine. Advances in treatment are so rapid that this monograph will soon be out-of-date.

QUERIES AND MINOR NOTES

EXCESSIVE X-RAY EXPOSURE

To the Editor:—*A man was given a diagnosis of duodenal ulcer while in the Army in 1925. He left the service in 1927 and was examined by the Veterans Administration in 1932 and then no more until 1947. These examinations included gastrointestinal x-ray series. Since 1953, the VA facility has what is now termed an ulcer clinic. Routine blood and urine examinations plus chest x-ray and gastrointestinal series were performed three times in 1954, twice in 1955, and once so far in 1956—with another scheduled in six months. Apparently this procedure is to go on indefinitely. Is this too frequent x-ray exposure?* *M.D., Texas.*

Answer.—It is not believed that the gastrointestinal examinations made prior to 1953 were too frequent. Since 1954, the patient has had six complete gastrointestinal examinations. Two series in one year is believed to be within safe limits, if the examinations are not carried out over a number of years. It is also important that the fluoroscopist does not consume too much time or that an excess of spot films are not made during the examination. The usual fluoroscopic factors are 80 kv. peak, 5 ma., 1 mm. of aluminum filter, 13 in.-target tabletop distance. With these factors, the intensity is approximately 7 r per minute. The factors used in making spot films are 80 kv. peak, 150 ma., 1 mm. of aluminum, 13 in.-target tabletop distance. Intensity is 4 r per second or 240 r per minute. If the usual number of films are exposed, plus the fluoroscopic and spot films, the patient received in the neighborhood of 67 r. Gallbladder examination is not included in this estimate. Three complete gastrointestinal examinations as a yearly plan is beyond the safe limits and is not necessary. One gastrointestinal x-ray examination a year to check a duodenal ulcer should be enough, unless an emergency arises. Much has been written lately on the deleterious effects of irradiation on the gonads and also about the effect upon the blood cells. It is safe to carry out x-ray examinations when needed, provided the radiologist is familiar with the output of his machines. One should be very careful, especially in examining youngsters, as mutation with gradual evolution and alteration in heredity and in the germ plasm may become evident in later generations.

PAINT REMOVERS

To the Editor:—*A patient, aged 48, complains of having been extremely tired at night for the past nine months. During this time, he intermittently used a paint and varnish remover that contained methylene chloride. The blood cell count was as follows: hemoglobin level, 13 gm. per 100 cc.; red blood cell count, 4,600,000 per cubic millimeter; hematocrit, 44%; white blood cell count, 9,600 per cubic millimeter; total neutrophils, 67%; lymphocytes, 29%; eosinophils, 1%; monocytes, 3%. Blood chemistry studies were as follows: blood sugar level, 103 mg. per 100cc.; urea nitrogen level, 14 mg. per 100 cc.; cholesterol level, 200 mg. per 100 cc.; cholesterol esters, 70%; calcium level, 10.7 mg. per 100 cc.; phosphorus level, 3.1 mg. per 100 cc.; total protein level, 6.1 gm. per 100 cc.; albumin level, 3.8 gm. per 100 cc.; globulin level, 2.3 gm. per 100 cc.; thymol turbidity, 1.2 units; cephalin flocculation test, negative; alkaline phosphatase, 1.0 Bodansky units; acid phosphatase, 0.3 Bodansky units; and Kahn test, negative. Would this solvent produce such clinical findings?* *M.D., New York.*

Answer.—This query fails to provide any substantial information as to the extent of exposure. "Intermittently" is subject to endless variation. No precise opinion in reply is warranted. In general, currently applied paint removers fall into two categories. The long-used ones contain benzene (benzol) along with acetone, methanol, and paraffin wax. The paraffin and acetone constitute minor affronts to health, systemic methanol poisoning is practically unknown from industrial exposure, but the benzene is highly toxic and the conditions of applying paint remover are conducive to severe exposure. Yet the laboratory picture provided is not descriptive of benzene poisoning. Shortly after exposure to benzene the fact of exposure may be established by the readily conducted urine-sulfate test, which, when positive, is characteristic of benzene exposure but not of benzene poisoning. The newer paint removers are likely to contain methylene chloride as the chief constituent along with paraffin or methyl cellulose and some solvent less evaporable than methylene chloride such as toluene (toluol). Collier, cited by Browning (Toxicity of Industrial Organic Solvents, rev. ed., London, Her Majesty's Stationery Office, 1953, p. 123), describes a series of intoxications from methylene chloride present in paint removers. He notes: "The symptoms in the two most severely affected patients who had to leave work were, however, largely subjective, and the evidence was rendered to some extent indefinite by the presence of intercurrent affections, lead poisoning in the one and duodenal ulcer in the other. The first complained of irregular but severe pains in legs and arms, hot flushes, headache, vertigo, stupidity while at work, difficulty in reading on account of eyesight not being clear, anorexia, precordial pain, rapid pulse, shortness of breath, fatigue on exertion and attacks of rapid beating of the heart. No objective abnormalities were present with the exception of haematological changes including slight anaemia and punctate basophilia, attributable to his previous exposure to lead. In the second case the subjective symptoms were very slight, e. g., drowsiness, pains in the head, irritability and tingling in the hands and feet, and a diagnosis of gastro-duodenal ulcer was made on admission to hospital." However, the present-day consensus is that methylene chloride as applied in industry is relatively harmless. It may be noted that "fatigue" appears in the list of subjectives symptoms.

DRINKING WATER WITH A LOW pH

To the Editor:—*In this area there are many instances of drinking water with a low pH, as determined by an independent laboratory. Several statements by those supposedly well informed indicate that a pH reading of 6.5, or lower, in drinking water might cause tooth decay, gallstones, kidney stones, and nonspecific "indigestion." Please enlighten us on this matter.* *John W. Nance, M.D., Clinton, N. C.*

This inquiry was referred to two consultants whose respective replies follow.—Ed.

Answer.—The pH is not a specific entity but is a measure of the degree of acidity or alkalinity. Many natural waters have an acid reaction, while others have an alkaline reaction. In general, the compounds that cause acidity (pH 6.9 and lower) are some form of sulfur, chlorine, phosphorus, or organic acids. Those compounds that cause alkalinity (pH 7.1 and higher) are principally calcium, magnesium, potassium, and the carbonates. A pH of 6.0 to 6.9 is only very slightly acid. Most distilled waters fall into this pH range. With the possible exception of tooth decay, none of the conditions named appear to be related to the pH of drinking water. In regard to tooth decay, there should be

---

The answers here published have been prepared by competent authorities. They do not, however, represent the opinions of any medical or other organization unless specifically so stated in the reply. Anonymous communications and queries on postal cards cannot be answered. Every letter must contain the writer's name and address, but these will be omitted on request.

no concern over a water supply until the pH falls to at least pH 5.0. Exposure to water supplies with a lower pH (below 5.0) over a prolonged period of time might possibly have some decalcification effect on enamel.

Answer.—Adequate data are not available on the health hazard of consuming waters of low pH value. However, many common canned foods and beverages have lower pH values than most potable waters. The following table gives representative pH values of some common canned or bottled foods.

Canned Foods	Representative pH Value	Canned Foods	Representative pH Value
Apples	3.4	Grapefruit juice	3.3
Asparagus	5.5	Lemon juice	2.4
Beans, green	5.7	Milk, evaporated	6.2
Carbonated beverages	<3.0	Peaches	3.8
Carrots	5.2	Potatoes, white	5.5
Cherries, red	3.5	Spaghetti in tomato sauce	5.1
Coffee	5.5	Tomatoes	4.3
Corn	6.1		

Also it is important to remember that stomach contents normally range from a pH of 3 to 6.8.

In view of the relatively low pH of much of our food and of the excellent buffering properties of gastric and duodenal juices, it seems unlikely that drinking water with a low pH value (such as 5.5-6.5) could be significant in producing gallstones, kidney stones, or "indigestion."

There is some disagreement among dentists as to the existence of an association between consumption of lemon juice and the production of dental caries. Lemon juice has a much lower pH than most potable waters. It seems unlikely, then, that drinking waters with pH values falling within the range commonly found in unpolluted waters have the effects mentioned in this query.

TELEVISION

To the Editor:—*Are there any glasses especially helpful in viewing television? I have many complaints of discomfort of that kind.*

M.D., Maine.

This inquiry was referred to two consultants, whose respective replies follow.—Ed.

Answer.—Television should cause no ocular discomfort in healthy eyes if the image is clear and viewed with the proper correction and with the proper distribution of illumination in the room. Watching the screen in a completely dark room is undesirable, as central glare then results and the image may lose sharpness because of pupillary dilatation. Only clear distance-vision glasses should be used. Tinted lenses of any type whatsoever reduce the light entering the eye and are hence detrimental. But lenses with antireflection coating of magnesium fluoride admit more light to the eye and consequently should add to the clarity of the view. When discomfort arises, the most common cause is conjunctival asthenopia. The conjunctival hyperemia usually responds to instillations of zinc sulfate, ½%; cold compresses; and, if necessary, eye drops of epinephrine chloride (1:1,000). The corticosteroid eye solutions are also effective.

Answer.—There are no unusual conditions in viewing television that require special glasses. Most television sets are adjustable as to position, distance from the viewer, brightness, contrast, and focus. In some localities the view is variable due to interference beyond control of the viewer. When conditions are adjusted to the best possible extent by the viewer for his comfort, including eye comfort, one should be able to view the picture without unusual eye strain. At the optimum distance for viewing television, 15 ft. or more, only distance glasses are used. For those who need to wear glasses for distance, the same correction is worn for television. There is nothing to be gained by wearing tinted glasses, filters, or other optical appliances while viewing television that are not used for full-time wearing of glasses for distance. It is not advisable for adults to view television for longer than a few minutes at distances less than 12 ft.

HYPNOSIS AND CHOREA

To the Editor:—*Can the physical movements of Sydenham's chorea be removed during hypnosis? Also, since the movements of Sydenham's chorea disappear in sleep, will they disappear in a sleep-like hypnotic trance? If the movements of chorea can be removed temporarily for the duration of a hypnotic trance, does it prove that this is actually psychogenic chorea and not Sydenham's chorea?*

M.D., Missouri.

This inquiry was referred to two consultants, whose respective replies follow.—Ed.

Answer.—Since choreic movements are greatly affected by the emotional state of the patient, it is difficult to determine how much of the condition is actually due to organic disease. Without a detailed history it would be difficult to come to a conclusion as to whether the symptoms are primarily psychogenic. It is a well-known fact that the conscious part of the brain is placed at rest during sleep, while the unconscious continues in activity. Many experiments have been carried out that indicate that persons suffering from chorea of one form or another will have a disappearance of symptoms while under the effects of hypnosis, as they do while in natural sleep. If the hypnotic treatment is continued over a period of months and frequently repeated, the will to control the movements becomes increasingly effective. The therapeutic value of hypnosis depends on posthypnotic suggestion. Consequently, if the will to control is well implanted in a person's mind, it is quite possible that the effects of the suggestion may be continued over an extended period. On the other hand, it should be remembered that hypnosis is not a permanent method of cure. Without adequate insight, hysterical reactions may return if the patient is under sufficient stress. One or two treatments under hypnosis is not an adequate test in evaluating this type of treatment.

Answer.—The temporary cessation of the choreal movements during the hypnotic trance does not rule out Sydenham's chorea, since hypnosis and/or strong suggestion reduces tremors and other movements, such as ballism or tics, of basal ganglionic origin. Inasmuch as peripheral chronaxy is heightened and lowered by suggestion, nerve function can be improved by scientifically applied suggestion-hypnosis, thus hastening the recovery of patients, especially those with the reversible neuropathological changes that characterize Sydenham's chorea.

TISSUE STAINING FOR AMYLOIDOSIS

To the Editor:—*Please suggest the most efficient staining techniques for demonstrating primary amyloidosis.*

Harry Shecter, M.D., Philadelphia.

Answer.—Variations in the staining reactions of amyloid and in the intensity of color absorption with specific stains is commonly observed in primary systemic amyloidosis. Therefore, several staining procedures should be used. Fixation of the tissues in a 10% formaldehyde solution or absolute alcohol is prescribed, but good results are obtained with tissues fixed in Zenker's solution. A permanent efficient procedure is with the crystal violet stain (Lieb: *Am. J. Clin. Path.* 17:413, 1947). Deparaffinized sections are immersed in about 0.3% crystal violet solution for one to three minutes (10 cc. of saturated alcoholic crystal violet solution in 1 cc. of hydrochloric acid and 300 cc. of distilled water; the stock crystal violet solution consists of 14% crystal violet in 95% alcohol). Check under the microscope. Rinse well in tap water and mount from water in a solution of 50 gm. of Abopon and 25 cc. of distilled water. (Abopon is a water-soluble synthetic resin, available from Glyco Products Co., 148 Lafayette St., New York. Mix Abopon with water under heat.) The amyloid becomes purplish-red (violet), while other tissue elements are stained blue. The shade of the violet varies. A second good method is Bennhold's Congo red stain (*München. med. Wchnschr.* 69:1537, 1922). It stains amyloid pale pink to red in frozen, paraffin, or celloidin sections. Stain slides in a 1% aqueous solution of Congo red for 10 to 30 minutes, or longer if a deep color is desired. Dip the sections in a saturated aqueous solution of lithium carbonate for 15 seconds; decolorize in 80% alcohol until the stain no longer is removed. Wash in water for 15 minutes, counterstain with alum hematoxylin for 1 to 2 minutes, wash in water, dehydrate in 95% and absolute alcohol, xylene (xylol), and mount in balsam. If substances thought to be amyloid fail to give these staining reactions, one of the collagen stains to differentiate amyloid from ordinary hyalin can be used.

RECURRENCE OF HERPES ZOSTER IN THE SAME AREA

To the Editor:—*A 36-year-old woman has periodic recurrence of almost typical herpes zoster of the zygomatic branch of the trigeminal nerve. The attacks began about eight years ago, coming on each year at first, then twice each year, and now every three or four years. The lesion this time consisted of typical clusters of herpetic lesions over the zygomatic branch, left side, with edema of the cheek and enlargement of the corresponding cervical lymph node. Tenderness was in the supraorbital and infraorbital nerves. Twice she says she had extension of the lesion into the conjunctiva of the eye. Blood cell count, Kahn test, and urine examinations were normal. X-ray pictures of sinuses showed nothing abnormal. The symptoms follow a fixed routine, being very similar each time. Between attacks she has no symptoms. There is no sensory or motor disturbance except the pain. Does herpes zoster recur in the same location? What type of focal irritation to the root could repeat in this manner? Is there any treatment to prevent recurrence?* *John D. Gleckler, M.D., Denison, Texas.*

Answer.—Instances of herpes zoster in which the condition recurs periodically at the same site have been observed, but many authorities express the belief that in such cases the condition is really a herpes simplex, even though it does appear to follow a specific nerve root distribution. It is often stated that herpes zoster may be either idiopathic or symptomatic and that in the latter type some local lesion of the nerve roots or systemic disease may serve to activate the infection and determine the site of involvement. Carcinoma, Hodgkin's disease, and leukemia are frequent etiological agents in this latter type. Search should be made for both systemic disease and focal irritation or disease in the region of sensory roots of the left trigeminal nerve.

HEMORRHAGE AFTER TONSILLECTOMY

To the Editor:—*How could one detect post-tonsillectomy hemorrhage before signs of shock develop in a child who is still unconscious from anesthesia?*

Jacob Greenblatt, M.D., Stamford, Conn.

Answer.—Because no statement of details about premedication and anesthesia is given, an answer must be in general terms. Preoperative sedation should be carried out about two hours previous to the intervention. It is true that the effect will not be as pronounced as when given one hour previously, but the calming influence will still be there and the patient will stir much sooner. All doses should be calculated for the individual patient concerned. The general anesthetic (usually ether) should be so given that the child will react and vomit shortly after the surgeon is through and while the patient is still on the operating table. Hemostasis should be meticulous. Patients treated as outlined above, even if they bleed, will be so far awake that all fresh blood from the nose and mouth will be quickly visible and act as a warning; furthermore vomiting will take place early, before much blood loss. It is the deeply narcotized and anesthetized patient who acts as described above, and the taking of blood pressure readings will be an unsatisfactory safeguard. It goes without saying that a properly trained attendant should be constantly present with children returned to their rooms after tonsillectomy.

ICE BAGS APPLIED TO CHEST FOR HEMOPTYSIS

To the Editor:—*What is the rationale in applying ice bags to the chest in persons with tuberculosis who are having hemoptysis? These people are usually quite ill, and it seems this treatment only causes worse physical and mental distress and does no good.* *T. R. Pratt, M.D., Pismo Beach, Calif.*

Answer.—Ice bags were long applied to the chest of tuberculous persons during and immediately after pulmonary hemorrhage. This procedure was never on a rational basis. In 1922, Fishberg said, "The time-honored ice bag applied to the chest is of no value at all excepting to keep the patient busy and attentive while attempting to keep it in place." From about 1 to 3% of pulmonary hemorrhages have proved fatal because of profuse bleeding resulting in cerebral anemia or to aspiration of blood in sufficient quantity to cause suffocation. Usually these are sudden deaths. However, the great majority of hemorrhages come under control without immediate complication with or without the use of ice bags. Thus, any useless procedure could be introduced and extravagant claims made for it. It is not unusual for small to moderate amounts of blood to be aspirated into bronchial ramifications during hemorrhage. These, together with surrounding reaction, cast shadows on x-ray films, which may be in evidence for weeks or longer. In some such cases, pneumonia develops in such areas. It is believed the ice bag may invite the development of pneumonia. The ice bag should be classified as an anachronism in the sense that it is being used long after it was found to be of no value and, possibly, harmful. In cases of persistent, extensive bleeding, artificial pneumothorax has been successfully used. When this is impossible because of adhesions, surgical resection may become necessary.

TREATMENT OF SYPHILIS AND PENICILLIN SENSITIVITY

To the Editor:—*What therapeutic procedure should be followed in cases of cerebrospinal syphilis in which the process is active and a penicillin sensitivity has developed? Specifically, what would be the procedure in cases showing an anaphylactic reaction and those showing apparently minor skin reactions? It is understood that the reactions mentioned are associated with old syphilis and not with recent infections.*

R. L. Nattkemper, M.D., Napa, Calif.

Answer.—In the treatment of cerebrospinal syphilis, when a penicillin sensitivity has developed, treatment with that drug should be immediately and permanently discontinued. This applies particularly to anaphylactic reactions but should also apply to minor skin reactions, since the latter may be prodromal to more severe reactions from which a fatality could occur. However, other antibiotics may be employed and are preferable to arsenicals such as oxophenarsine hydrochloride hemialcoholate (Mapharsen) or neoarsphenamine. In the order of choice, oxytetracycline (Terramycin), chlortetracycline (Aureomycin), tetracycline (Achromycin), or chloramphenicol (Chloromycetin) are all to be considered. The usual average dosage is 2 to 4 gm. daily, in divided dosage, usually continued if tolerated for four weeks.

PREPUBERAL BREAST PAIN

To the Editor:—*An 11-year-old girl complains of pain in nipples, areolas, and breasts. There is no evidence of trauma, tumor, infections, or congenital defects. What factors may be present to cause the pain? How frequently does pain occur in the prepuberal period? What is the suggested treatment?*

Joseph V. Waitkunas, M.D., Woodhull, Ill.

Answer.—Pain in the nipples and breasts is an infrequent symptom in girls of prepuberal age. However, the condition such as you refer to has been described in some of the older works on diseases of the breast. Pain may be due to trauma of the nipple, which may not be evident on examination, such as from pinching, squeezing, or other forms of traumatic nipple stimulation; even the possibility of foreign body, such as needles inserted into the nipple ducts, must be considered. The condition is much more likely to be what older works on the subject call "the hysterical breast." This was known as early as 1667, when it was described by Willis, and is characterized by pain, tenderness and swelling of the breast, and reluctance on the part of the patient to submit to examination. When a diagnosis has been established, and the possibility of foreign body has been eliminated (x-ray examination if necessary), a frank discussion with the patient, with the assurance that there is no actual disease or tumor growth present, is usually sufficient. The patient should not receive hormones or physical therapy, but psychotherapy may become necessary.

TETRACYCLINE AS A FOOD PRESERVATIVE

To the Editor:—*With a chicken bought recently was a statement that tetracycline had been used as a preservative. Is there any danger of either sensitizing people to this drug or creating a resistant bacteria that would not respond to later medication with this drug? If this is successful in reducing spoilage in fowl and fish, is there not a danger that this food will be left too long on open shelves?*

Walter B. Cox, M.D., Missoula, Mont.

Answer.—Since Nov. 23, 1955, it has been permissible to use chlortetracycline for the preservation of freshness in dressed poultry. Chlortetracycline is usually added to the mixture of ice and water in which chickens are cooled after evisceration in poultry processing plants. A tolerance level of 7 ppm for residues of chlortetracycline in or on uncooked poultry has been established. Experimental evidence has shown that cooking destroys the antibiotic. Theoretically, therefore, the consumer is not exposed to antibiotic activity. The question of sensitization of a large human population was given serious consideration prior to the establishment of the tolerance level in uncooked poultry. Chlortetracycline is being widely used in the commercial fishing industry to assist in the shipboard preservation of the catch. Experimental work with other antibiotics in food preservation is in progress. The retailer is interested in what he calls the extension of shelf life of perishable products. Chickens and fish properly treated with chlortetracycline do have a longer shelf life. The retailer must assume the same responsibility as previously with respect to sanitation and edibility of a product. Antibiotics reduce, not prevent, spoilage, and vigilance must be exercised to guarantee safety of all perishables.

ALLERGENIC EFFECT OF PENICILLIN

To the Editor:—*In preparing a solution of penicillin for sensitivity skin testing, may the solution be kept indefinitely and still be reliable as a test solution? Does outdating of the penicillin affect its reliability as an ingredient of the test solution?*

M.D., West Virginia.

This inquiry was referred to two consultants, whose respective replies follow.—Ed.

Answer.—There is good evidence that the allergenic activity of penicillin solutions is far more stable than its antibiotic property. Penicillin moderately "outdated" is probably still potent allergenically. Weak solutions of penicillin have been kept for a long time, with little impairment of its allergenic qualities. It is very unlikely that such solutions can be kept active "indefinitely." It is not known exactly for how long they remain active.

Answer.—Solutions of penicillin to be used for sensitivity determination by skin testing are best made up fresh. If penicillin is allowed to stand in solution for any appreciable length of time, it may deteriorate. Penicillic acid may be split off from the molecule, and the antigenic capacity of the antibiotic will probably be lost. If solutions of the antibiotic are to be kept for any length of time before they are to be used for skin testing, they are best kept in the frozen state. Outdating of penicillin does not impair its reliability as an ingredient of the test solution, providing the powder has been kept dry.

COLD SHOWERS AND ALLERGY

To the Editor:—*A 68-year-old man has been allergic most of his life to many inhalants, some foods, and currents of air contacting his scalp. The first two classes of allergens affect him periodically. The air currents produce coryza and nasal congestion any time he exposes his uncovered head to a draft of air. In an attempt to desensitize his scalp against air currents, he began to take cold showers in the mornings, five months ago, with no apparent effect. His general physical condition is fair. He works about 10 hours a day and has no time for hobbies or physical exercise. For the past four years, walking up steps has caused dyspnea. His pulse misses a beat irregularly, and chest x-ray shows moderate atherosclerosis of the aorta. Blood and urine are normal. Is there any hazard for him in cold showers?*

M.D., California.

Answer.—The history of this man suggests that the allergy to the inhalants is probably the primary condition. It is not uncommon for persons having a true allergy to experience acute reactions to physical stimuli, particularly to cold, dampness, and drafts. There are, of course, true instances of primary hypersensitivity to cold. Attention to the basic allergy in this patient might prove more profitable than any attempts to modify the physical hypersensitivity. If this proves unsuccessful, cold showers are worth trying. The history does not indicate any particular reasons for considering cold showers hazardous to this patient.

COUGH AND PAIN MEDICATION DURING PREGNANCY

To the Editor:—*What cough medicines and pain-relieving drugs can be administered to a pregnant woman without doing any harm to the fetus and without provoking abortion? What are the safer doses, taking into consideration especially such drugs as morphine, codeine, Dionin, phenobarbital, and papaverine?*

M.D., Turkey.

Answer.—The safe cough medicines and pain-relieving drugs used in nonpregnant patients may be administered to a pregnant woman without fear of harming the mother or inducing an abortion. The doses are the same for pregnant as for nonpregnant patients.

OLEANDER AND DECOMPENSATED HEART DISEASE

To the Editor:—*A patient with decompensated coronary heart disease is allergic to both digitalis and squill. Would oleander compound be of value and, if so, what company in the United States manufactures it?*

Harry R. Deane, M.D., St. Petersburg, Fla.

Answer.—Nerium oleander is a plant of the Apocynacea family, many of which contain glycosides with a digitalis-like action. Strophanthus is a member of this family. The active principle of oleander, oleandrin, becomes gitoxigenin on hydrolysis. This material is also the result of hydrolysis of gitoxin, one of the so-called pure glycosides of digitalis. With this background it seems likely that a patient who was allergic to all of the digitalis glycosides would also be allergic to the glycosides of oleander. Oleander disappeared from medical practice in the United States many years ago, although reports in the foreign literature indicate that it is used, but rarely, on the European continent. Inquiries at three large urban pharmacies failed to discover a preparation of oleander or to elicit information as to where such a preparation might be found. There are four purified glycosides of digitalis readily available today in any pharmacy. In additon there are strophanthin and ouabain. It would seem reasonable to suppose that one of these preparations would prove effective in the above instance without producing undesirable side-effects.

PERFORATIONS OF TYMPANUM

To the Editor:—*In 1952, I was struck by lightning while deep-sea fishing and sustained a basilar skull fracture and ruptured both tympanums. The residual is nonserviceable hearing in the left ear with an open tympanum and 60% loss of hearing in the right ear with a healed intact tympanum. At times I am exposed to a water hazard in which there is possibility that my head might be submerged momentarily under water. I should like information as to an appliance or, if necessary, an operation, if the latter could seal off my middle ear. Obviously, I would prefer an appliance, if such exists, that will answer the problem—even for exposure to accidental pressures, say at a depth of 10 to 15 ft. of water.* M.D., *New York.*

Answer.—Closure of long-standing tympanic membrane perforations is an accepted procedure. One method recently described by E. L. Derlacki (Repair of Central Perforations of Tympanic Membrane, *A. M. A. Arch. Otolaryng.* 58:405 [Oct.] 1953) consists of a series of office treatments and is successful in better than half of the cases, even when the perforation involves a large portion of the tympanic membrane, provided there is an intact margin. More recently methods of closing perforations by surgery have been described in the foreign and American literature. Meanwhile occlusion of the meatus with lamb's wool to which petroleum jelly has been applied generally secures a water-tight protection against immersion.

DERMATITIS FROM CHLORINE

To the Editor:—*A patient has extensive dermatitis of the hands that seems to clear up when she moves to an area with an unchlorinated water supply. Hypochlorites and other chlorine bleaching compounds make the dermatitis definitely worse. However, this woman now lives in an area in which the municipal supply is chlorinated. Is there any way to counteract the chlorine in the water?*

Everett C. Campbell, M.D., Woodsville, N. H.

Answer.—There is no known simple and practical way of removing free chlorine from municipal water supplies other than by boiling or by allowing the water to stand overnight in containers with maximum surface exposure to the air (tubs, dishpans, etc., rather than bottles). These methods will serve to remove free chlorine but will not remove chlorinated derivatives that may also be present in such water and that have been claimed to be capable of producing allergic reactions in sensitive individuals. Perhaps the use of protective creams, such as those containing silicones (New and Nonofficial Remedies, 1956, p. 479), might be tried, since it would hardly be feasible to employ distilled water for dishwashing, laundering, and other household uses.

FLYING AFTER OCCURRENCE OF PNEUMOTHORAX

To the Editor:—*A 28-year-old male has just had his second spontaneous pneumothorax in three years. The first occurred while he was in military service and it was presumed to be due to a bleb; the etiology of the present episode is undetermined. This man holds a private pilot's license for small planes. From this information, can it be stated whether he should fly after recovery, and, if so, would there be any altitude limitations?*

F. H. McClain Jr., M.D., Mount Union, Pa.

Answer.—The history of two episodes of spontaneous pneumothorax within a three-year period indicates that this individual is a good candidate for repetition of the incident. He, therefore, represents a poor risk as a flyer, in that he compromises flying safety. Whether a bleb was actually proved in the first episode is not obvious in the question as stated. It would be advisable to study the case thoroughly, including laminograms. If blebs are identified and are on the same side as the pneumothorax, surgical removal of the pathology may rehabilitate this man and permit flying. However, recovery must be complete after surgery, including a return to normal pulmonary function.

COOKING WITH MINERAL OIL

To the Editor:—*Is there evidence that cooking with mineral oil results in the formation of carcinogenic agents from oil decomposition?*

Daniel J. Reagan, M.D., Worcester, Mass.

Answer.—There is no conclusive evidence indicating that mineral oil, when used in cooking, is decomposed to form carcinogenic substances. The use of mineral oil in cooking is not a desirable practice; it is well known that the ingestion of mineral oil interferes seriously with bodily absorption of the fat-soluble vitamins carotene, vitamin D, and vitamin K.

HAZARDS IN USING OXYGEN TENT

To the Editor:—The Journal, *June 30, 1956, page 934, in the answer to a query entitled "Hazards in Using Oxygen Tent," contains the extraordinary statement that a spark of static electricity could start a conflagration in an oxygen tent under certain circumstances, such as the use of nylon in any form, sheets or bedclothes, as well as the use of wool blankets. We do not believe there is any evidence to support such a contention. It is of considerable importance to question the authority of the consultant to answer the query, not only from the point of view of fact and theory but also because a medicolegal basis for suit would exist when a fire did occur during the use of an oxygen tent. We have never been able to start a fire with deliberately produced static sparks on wool blankets in atmospheres of 40 to 50% oxygen. Our studies were made in oxygen chambers many years ago to test this point. Since confusion exists regarding the hazard of fire in the presence of oxygen as contrasted to that in the presence of flammable or explosive gas atmospheres as found in operating rooms, the following discussion is presented.*

For a fire to start under any conditions two factors are necessary: (1) a flammable or explosive material and (2) a source of heat sufficient to raise the temperature of the material above the kindling point. Certain anesthesia gases are flammable and have a very low kindling or flash point; hence a static spark may ignite them very easily. In contrast, oxygen is not flammable; it only supports combustion. For a fire to start in an oxygen atmosphere it is necessary that the flammable material in the oxygen atmosphere start burning. The kindling point of cotton sheets or wool or nylon blankets is considerably higher than that of the afore-mentioned anesthesia gases; hence it is much more difficult to ignite them. The presence of greater or lesser amounts of oxygen does not affect the kindling point of the material mentioned.

A static spark obtained from wool blankets or nylon uniforms has sufficient heat and intensity to raise the temperature of explosive gases above the kindling or flash point. It cannot, however, do this with bedclothes, etc. Therefore, there is no danger of fire from this source in oxygen atmospheres. While static sparks do not create a hazard in oxygen tents and in rooms, the presence of electrical appliances, any of which may "short" or spark, does. Electrical appliances and open flames should be rigidly excluded. We have been advised by the Linde Air Products Company that their Safety Codes Division, which has kept accurate records of practically all oxygen fires in the United States during the past 25 years, finds that about 90% of these fires have been caused by smoking. They further state that, of the remaining 10%, some were probably caused by smoking, although the evidence for this belief could not be definitely obtained. Other sundry causes have been open flames from alcohol lamps placed in tents, sparks from electrical appliances, and burning candles.

Alvan L. Barach, M.D.
Morris Eckman, B.S.
929 Park Ave.
New York 28.

The above letter was referred to the consultant who answered the Query and Minor Note under discussion. His reply read as follows:

> *I agree with the writers that ordinarily a spark of static electricity would not cause a fire in an atmosphere of 40 to 50% oxygen. Experimentally one might attempt it 1,000 times with negative results, but on the 1,001th try have a positive result. One must not overlook the fact that patients expel intestinal gases and exhale anesthetic gases during recovery from anesthesia. There is always the possibility of low combustion point of foreign material having been spilled on bedding under the tent. The National Fire Protective Association's "Standard for Nonflammable Medical Gas Systems," which has been adapted by the National Board of Fire Underwriters, specifically prohibits wool blankets and nylon fabrics within an oxygen tent. This was approved, along with other rules, by the Committee on Hospital Operating Rooms and the Committee on Gases, both of which are made up of outstanding experts on this subject. The majority of oxygen tent fires have been shown to result from persons smoking under the tent, but some have not been explained. This, therefore, is no argument against the possibility of static causing a fire.*

TREATMENT OF TRICHURIASIS

To THE EDITOR:—*In Queries and Minor Notes in* THE JOURNAL, *Aug. 25, 1956, page 1719, there is a treatment for trichuriasis. I should like to comment on this subject. Light infestations by Trichuris trichiura (one or two eggs per preparation for direct examination) do not require treatment, because the number of parasites is so small that no ill-effects are produced in their host. Heavier infestation may be treated with enemas of 1:300 colloidal hexylresorcinol carried to the cecum. To date, no other treatment has been found equally effective. To assure success, these enemas must be carried to the cecum, preferably under fluoroscopic control. The evening before and two hours before giving the medicamentous enema, the patient must receive a cleansing enema with a 2% solution of salt in warm water.*

The medicamentous enema must be prepared as follows: hexylresorcinol, 3 gm.; mucilage of acacia, 90 gm.; barium sulfate, 90 gm.; and warm water, quantum sufficit, 900 cc. Generally, to fill the colon up to the cecum, adults need 1,000 to 1,500 cc. and children 15 to 20 cc. per pound of weight, or 100 to 150 cc. per year of apparent age. The enema may be evacuated 5 to 10 minutes after administration. Children frequently retain about a third of the amount used. Some cases are cured with the first enema; others require three or more enemas. These must be given at weekly intervals. Two weeks must elapse after the last enema, to allow for a new examination of feces. It must be stressed that the destructive action of colloidal hexylresorcinol, 1:300 solution, is so strong that the intestine becomes rid of Trichuris (Trichocephalus) organisms up to the level reached. Some patients have expelled over 2,000 Trichuris organisms after the first enema. The worms come out in pieces or almost totally disintegrated.

Trichuriasis is very common in Cuba. In this country, the dysenteric syndrome produced by the Trichuris organisms in children is more frequent than the one caused by Endamoeba histolytica or Balantidium coli. The differential diagnosis is easy, by means of scraping of the margins of the anus with a sterile cotton swab; microscopical examination will show, according to the case, Trichuris eggs (free or englobed in flocculi of mucus) or trophozoites and cysts of histolytica, or B. coli. A rectoscopic examination is valuable to establish diagnosis, because in children T. trichiura is found very often in the rectum-sigmoid (rectal trichuriasis). It is common to find rectal prolapse showing a reddish, edematous mucosa with small ulcerations and numerous Trichuris organisms adhered to it.

If the dysenteric syndrome produced by T. trichiura is not stopped quickly, the patient may die of gastroenteritis and dehydration in a few days. In cases of rectal trichuriasis with dysenteric syndrome, these enemas must be applied with no previous preparation (cleansing enemas). After the first enema the number of evacuations diminishes noticeably, and the stools become normally consistent and without macroscopic blood. Seventy-two hours later, the alarming clinical picture is almost completely vanished, and the patient recovers rapidly, clinically and parasitologically.

José G. Basnuevo, M.D.
Instituto de Medicina Tropical
Hospital Universitario
Habana, Cuba.

ARMY PERSONNEL "GASSED" DURING WORLD WAR I

To THE EDITOR:—*In Queries and Minor Notes, in* THE JOURNAL, *Aug. 18, 1956, page 1604, Dr. W. C. Hueper mentioned Case and Lea's report "Mustard Gas Poisoning, Chronic Bronchitis, and Lung Cancer"* (Brit. J. Prev. & Social Med. *9:62, 1955). It should be mentioned that, according to these British authors, over 80% of surviving World War I pensioners who suffered from mustard gas poisoning were affected by chronic bronchitis some 15 years later. This seems to indicate that, contrary to the answer given to the original query* (J. A. M. A. *161:118 [May 5] 1956), the majority of "gassed" veterans do have residuals from their exposure to mustard gas. Dr. Hueper also mentioned that a statistically significant excessive liability to lung cancer was found in British veterans with mustard gas poisoning. However, he failed to add that, in the same study, a similar excess of lung cancer was found also in those veterans of World War I with chronic bronchitis who had never been exposed to mustard gas. Therefore, Case and Lea concluded that the evidence presented "does not support the view that mustard gas has acted as a direct carcinogen" but indicates that chronic bronchitis may be associated with the subsequent development of pulmonary malignancy. Bolt and Lew* (J. A. M. A. *160:736 [March 3] 1956) also demonstrated that chronic bronchitis of any etiology increases significantly the risk of death from respiratory cancer. Indeed, more and more pathological and clinical investigations, most of them conducted abroad, indicate that pulmonary malignancy may be a late sequela to profound chronic and scarring processes in the lungs, be they initiated by chemical or mechanical injuries, epidemic influenza, or tuberculosis (Finke:* Internat. Rec. Med. *169:61, 1956).*

Walter Finke, M.D.
333 Park Ave.
Rochester 7, N. Y.

SCHIZOPHRENIA

To THE EDITOR:—*In* THE JOURNAL, *Sept. 8, 1956, page 152, in Queries and Minor Notes, it is stated that "in cases of schizophrenia, for 'patients who are moody, nontalkative, and depressed and who have been mentally ill for many years,' the ideal treatment should be a combined convulsive and insulin hypoglycemic treatment. . . . [but] even with this most energetic form of treatment, one cannot assume more than about 15 to 20% probability of a favorable response."*

It seems to me that where the consultant's "ideal treatment" offers no more than a 15 to 20% cure, other possible forms of therapy should at least be mentioned. In recent years, some psychotherapists have been treating even chronic schizophrenia with modified psychoanalytic techniques. This is at best a difficult, specialized therapy, still in its investigative and developmental stages, with many variations from therapist to therapist, and for which few statistics are available; but such results as have been published and my own experience would indicate as good, or better, expectations than the 15 to 20% with combined convulsive and insulin treatment. Incidentally, the consultant also makes no response to the query about "serious side-effects"; there is, of course, significant hazard and mortality connected with the recommended treatment. Further, in the present state of our psychiatric nosology, it seems ill-advised categorically to recommend a hazardous, relatively ineffectual therapy, simply because a patient has been sketchily described as "moody, nontalkative, depressed," and schizophrenic.

25 State Society Medicare Contracts Signed • •
Library of Medicine Surveys Dissertation Use • •
More Public Health Service Assignments Shifted • •
Health Conditions of Indians • •
Loans to Medical Schools • •

MEDICARE CONTRACTS

The Defense Department and medical societies that will serve as agents for the provision of medical care outside military facilities for armed forces dependents are moving rapidly toward a conclusion of negotiations. The contracts are expected to be completed with the societies in time for inauguration of the program Dec. 7. Approximately a month before the deadline, 25 societies either had formally signed contracts or had completed negotiations with the Defense Department. Contracts formally signed were with medical societies of Colorado, Washington, Indiana, Oregon, Montana, and Nebraska.

The department said there were no problems serious enough to interfere with formal signing of agreements covering California, Minnesota, Michigan, Wisconsin, North Dakota, North Carolina, Connecticut, Massachusetts, New Jersey, New Hampshire, Vermont, South Dakota, Illinois, Florida, Tennessee, Arkansas, Oklahoma, Wyoming, and Iowa. The Army is the agent for all uniformed services in handing medicare, with operations handled by the Office for Dependent Medical Care, headed by Major Gen. Paul I. Robinson.

SURVEY OF USE OF DOCTORAL DISSERTATIONS

The National Library of Medicine has made a survey on the use of its collection of doctoral dissertations in medicine. It found that the number of these requested per week averaged 19, compared with 35 several years ago, and that the largest number requested were from readers in the library itself, 38% as against 24% for interlibrary loan. Of the 44 universities whose theses were requested, 10 schools account for 64% of all requests.

In reporting on the survey, the library commented: "While it takes pride in its stewardship of the theses collection, the library has occasionally felt it necessary to evaluate the effort put into acquiring, processing, housing and servicing it. In the past few years, especially when space has been at a premium, the question of the considerable shelving which must be used to store the new and also the old theses has come up again and again with various solutions advanced each time. Basically, the position of the library is that if theses are valuable for medical knowledge, the necessary time, money and effort will be found and expended on them, otherwise not. But the value of a medical work is extremely difficult to measure and, like the value of circulating iodine in the thyroid, must be sought for indirectly. One such indirect method of determining the value of material in a library is by examining the frequency of its use." There still remain some unanswered questions, the library adds in a report in its monthly publication, before intelligent decisions can be made about the theses collection.

REASSIGNMENTS IN PUBLIC HEALTH SERVICE

More reassignments in the Public Health Service have been announced in the wake of the major shifts made several weeks ago by Surgeon General Leroy E. Burney. Dr. Donald W. Patrick, director of the 500-bed Clinical Center at Bethesda, Md., has been appointed medical officer in charge of the 541-bed PHS hospital at San Francisco. Dr. Patrick succeeds Dr. Kenneth R. Nelson, who comes to Washington as associate chief of the Bureau of Medical Services.

Dr. Nelson, in turn, fills the post left vacant by Dr. G. Halsey Hunt's appointment as director of a new Center for Research on Aging, to be set up at the National Institutes of Health. Dr. Patrick's post at the Clinical Center has been filled by Dr. Jack Masur, former chief of the Bureau of Medical Services. That bureau is now headed by Dr. John W. Cronin, former director of the PHS Hill-Burton hospital construction program. The bureau supervises PHS hospitals, the Hill-Burton program, Indian health programs, and the foreign quarantine service. In another shift, Dr. Burney appointed Dr. Edgar B. Johnwick as medical officer in charge of the National Leprosarium at Carville, La. He succeeds Dr. Eddie M. Gordon, newly appointed chief quarantine officer at Fort Monroe, Va.

HEALTH CONDITIONS AMONG AMERICAN INDIANS

In a question and answer booklet, the Department of the Interior's Bureau of Indian Affairs describes the conditions and problems of the American Indians in health, housing, and other matters. For more than a year, the Indians' health has been the responsibility of the U. S. Public Health Service, but the Bureau of Indian Affairs retains responsibility in other respects. The booklet points out the role of the PHS and notes that costs of Indian medical care are met through annual congressional appropriations. In health matters, the bureau says, the objectives are "to bring the health of the Indians to the level enjoyed by the rest of the population in a way that encourages self-reliance and

Washington News—Continued

independence and gives full recognition to their rights as citizens. This requires adapting the health program to the customs, traditions, temperament and culture of each tribe."

Health work is described as a cooperative effort between the PHS, the Bureau, tribal organizations, and the individual family members. "Tribal councils usually include committees on health," the report states, "and these committees work cooperatively with public health officials." Many Indians trained as practical nurses and sanitary aides are helping their own people, while employed by the PHS. Also at work on the reservations are some Indians who have medical degrees or nurses training. Other points in the booklet are as follows:

Some tribes completely support their own health facilities, with the full cooperation of the PHS.

The PHS provides direct medical care as well as public health services for disease prevention. Hospitals, sanatoriums, health centers, field clinics, and school infirmaries cooperate, and some Indians are cared for in private facilities at federal expense. In some cases state health departments assist.

To improve Indians' health conditions, the PHS has expanded the quality of curative medical care and at the same time has intensified its program to prevent disease through field health facilities and services, immunizations, case finding, public health nursing activities, maternal and child care, school health, sanitation, health education and dental public health, and curative services. Public health services are furnished without charge, but Indians financially able to do so are expected to pay for medical, hospital, and dental care according to a schedule established by the PHS.

Although originally it appears that Indians and non-Indian settlers were "on about equal terms healthwise," today Indians fall victim to more infectious and preventable conditions, attributable to the "present low standard of living among the Indians."

Although the tuberculosis rate for Indians is far greater than that for the rest of the population (12 times in 1954), progress is being made through x-rays, surgery, occupational therapy, inoculations, antibiotics, and general rehabilitation.

LOANS TO MEDICAL SCHOOLS

The 12th loan to a medical school for construction of dormitory facilities has been made by the Community Facilities Administration (CFA), an affiliate of the Housing and Home Finance Agency. The CFA announced a $1,100,000 loan to Indiana University Medical School for a dormitory addition. Since the program began in 1950, the agency has loaned about 500 million dollars to institutions of higher learning for such improvements as dormitories, dining rooms, student unions, and infirmaries. Of this total some 14 million dollars has gone to 12 medical schools.

Money is loaned for a 40-year period at 2⅞% interest. Criteria for a loan include the following requirements: 1. The institution must offer a two-year program acceptable for full credit toward a baccalaureate degree. 2. The school must be nonprofit. 3. Additions or new construction must not be of extravagant or elaborate design. 4. Construction excludes class rooms, gymnasiums, or stadiums. When Congress voted the program it approved 300 million dollars in loan authority; this was raised to 500 million dollars in 1955 and to 750 million dollars this year. Applications for loans are available at the six regional offices of the housing agency, at New York, Philadelphia, Atlanta, Chicago, Fort Worth, Texas, and San Francisco.

SURVEY OF NURSING HOMES AND GENERAL HOSPITALS

A nationwide survey of the geographical distribution of nursing homes and general hospitals providing skilled nursing service has been completed by the Public Health Service The report includes 564,826 beds in 5,200 general hospitals and 171,106 beds in 6,531 skilled nursing homes. Patterns of the study reveal that in metropolitan counties there are approximately 4.1 general hospital beds and 1.3 beds in skilled nursing homes for every 1,000 population, while isolated rural counties have 1.8 hospital beds and 0 4 beds in nursing homes for 1,000 The supply of beds tends to increase in proportion to the per capita income and the number of doctors and nurses. Beds in nursing homes increase in accordance with the number of persons aged 65 or older. The complete study was published as Public Health Monograph No. 44, and the patterns are discussed by Jerry Solon and Anna Mae Baney in the October *Public Health Reports.*

DIABETES PROGRAM GUIDE

The Department of Health, Education, and Welfare has published a Diabetes Program Guide to aid states in improving their public health work in this area. The first part of the booklet discusses briefly the groups that might cooperate in conducting a diabetes program, the educational channels that could be used, and the various sectors of the population that would profit most from the program. However, as these factors vary from community to community, the high point of the pamphlet is the detailed outline of diabetes tests, equipment and personnel needed, and costs. The appendix suggests record forms and letter forms. This information provides a concrete basis for planning and conducting a control program. Nationwide use of diabetes control would prevent the occurrence and progression of the disease and would contribute to the scientific knowledge of the disease.

MISCELLANY

The steady expansion of activities for children and the changes in a child's life in the 20th century are reviewed in a new history of the Children's Bureau, "Four Decades of Action for Children." . . . The United States Air Force Medical Service consultants will visit various U. S. A. F. medical installations in Europe and will attend a medical conference in Germany this month. . . . The Atomic Energy Commission announced that the auxiliary monitoring system operated by the Public Health Service has been discontinued. The monitoring system informs the public of the levels of radioactivity in the U. S However, the AEC continues its own around-the-clock monitoring. . . . The PHS is ready to act on grant applications for aid in building sewage treatment facilities.

(cont'd)

'LANOXIN' continues to offer the same advantages — only the name has been changed.

The full effects of each dose develop quickly to permit rapid appraisal of the need for additional drug. Moreover, the limits of the patient's therapeutic range, which may be reduced in the seriously ill, may be approached with relative safety because toxicity, if it develops, soon abates. For true balance and uniformity of therapeutic effect, prescribe 'LANOXIN' brand Digoxin.

Sincerely,

'B. W. & Co.'

THE OLYMPIC GAMES AND THE OLYMPIC IDEAL

Allan J. Ryan, M.D., Meriden, Conn.

• *The Olympic Games are of such a personal nature to the world that they can even override serious political differences between countries. Here is presented how athletic training, the forerunner of the games, had its beginning. In considering the trials and tribulations that befell the growth of gymnastic exercise, it will be seen that physicians are involved not only in the etiology but almost as equally as competitors in the actual contests. New organizations, such as the American College of Sports Medicine, assure greater participation by the medical profession in future athletic affairs.*

This year more than 70 nations will send representatives to Melbourne, Australia, to compete between Nov. 22 and Dec. 8 in the 11th Olympiad. Competition has already been completed in the seventh Winter Games at Cortina, Italy, and in the equestrian events held in June in Sweden, because of the six-month quarantine on horses required by Australia. Sixty-nine nations, a record number, sent competitors to Helsinki, Finland, in 1952. What is the nature of these contests, which draw the attention and participation of men and women from all over the world every four years and which can override serious and fundamental political differences to the extent that East and West Germany can unite to send a single team? How are they related to the ancient Olympic Games of Greece, and what is their sponsorship? Why should physicians be interested in these demonstrations of skill, strength, agility, and endurance?

Probably the most ancient of all sports is hunting. Although we have pictorial records of the practice of this activity from the ancient Egyptian and various Asiatic nations and fragmentary records of other competitive activities, we do not consider that these people looked upon these endeavors as sport in the modern sense. The early Irish tribes held their Tailtean games in the pre-Christian era, but our knowledge of this time is so obscured by mythology that we do not have a clear idea of these contests. The ancient series of Olympic Games held on the plains of Olympia in Greece are well documented from the year 776 B.C. until they were abolished by the Emperor Theodosius in 394 A.D. These games, therefore, for practical purposes, mark the beginning of the recorded history of athletics.

We do not know the exact reason for the introduction of the competitive foot race, which marked the first Olympic contest, into the religious festivals that had been celebrated on these plains probably for hundreds of years before that. We do know that, although the games were originated by the Eleans who were the inhabitants of that region, they soon shared control of the games with the Spartans, even when these two states were at war. During such times a "truce of the gods" was zealously observed for the period of the games. We should also realize that, during their thousand-year history, these games bequeathed to us not only a series of contests, many of which are practiced and enjoyed today, but also the ideal of amateurism in athletics, which is the basis of the widespread interest and participation in sports today. In fact, the games were eventually abolished, because they had become so corrupted by the gradual inroads of professionalism that they had lost their true character and inspirational force. The first recorded Olympic game consisted of a single contest. a foot race the length of the stadium, which we know was about 200 yd. long. It was won by Coroebus, who was by profession a cook. A monopoly of victories by the hosts was maintained until the 13th Olympic Games, when the first non-Elean was returned a victor. At the 14th games, a second race, twice the length of the stadium, was added, and at the 15th a still longer race. The 18th Olympics saw the introduction of the pentathlon, due to the influence of the Spartans. This was at first an elimination contest in which the competitors were gradually narrowed down as they progressed through the broad jump, javelin throw, foot race, and discus throw. The two best then wrestled for the championship.

Boxing was added to the program at the 23rd games, the four-horse chariot race at the 25th, and the pancratium (a very rough combination of boxing and wrestling) at the 33rd games. Gradually contests in art, sculpture, and music were also added. In fact, the term athlete originally applied to one who competed for a prize in the games, whether in musical, gymnastic, equestrian, or other competition. By the 77th Olympiad, the games lasted for five days and included two lengthy religious ceremonies. For the first time representatives of all countries bordering on the Mediterranean were invited. It was indicative of the international character of the games that the final victor at the last games in 394 A.D. was Varastad, an Armenian.

History of Athletic Training

Those who competed at the Olympic Games were expected to spend 10 months in hard preliminary training. As the number of events increased and competition became wider and keener, those without a considerable or independent income found it hard to devote the necessary time to training. At the site of the games, training table meals were provided. Fried and boiled foods and cold drinks were forbidden. Cheese, figs, and wheat bread were staples of the training diet. Most of the competitors abstained totally from wine during training periods. Only light conversation was permitted at meal times to encourage proper digestion. Women were never allowed to compete, and at first were not even allowed to witness the games. This prohibition was eventually disregarded after a mother came disguised as a man to see her son compete. The prescribed penalty of being hurled from a high rock was not invoked in her case, and thereafter women were gradually admitted as spectators. There was an upper age limit of 35 for all contestants. In later games, separate contests for boys and youths were arranged. All athletes competed without clothing and their bodies were salved with oil. This practice probably had more of a ritual than a practical significance, although it must have made the wrestling contests difficult.

Professional athletics, which was to prove the downfall of the games eventually, began in Greece about the fifth century B.C. During the early Roman empire, amateur athletes were virtually unknown. Moreover, professional athletes finally supplanted the gladiators, who were principally prisoners or slaves, in the public circuses. The professionals were mostly Greeks and were organized in guilds. The ancient philosophers and physicians were unanimous in condemning the profession of athletics as injurious to the mind and body.

In medieval times the nobility found their exercise in training themselves in the strenuous art of war, which involved principally hand-to-hand combat on foot or horseback. They practiced hunting for diversion as well as to supply the larder. The common people had their own games, such as throwing the stone, a type of football, and quarter-staff. Gymnastics survived principally in the families of professional acrobats who entertained the nobility. Edward III of England prohibited weight-throwing by statute, but Henry VIII tossed the heavy pole, threw the hammer, and pole-vaulted. He also excelled at the game that eventually became court tennis, which was played first in the dry moats of the French castles.

Italian physicians of the Renaissance revived interest in gymnastic exercise for therapeutic purposes. Little general attention was paid to this subject, however, until the early 19th century. F. L. Jahn, a Prussian, devised a series of exercises for his Turnhalle gymnasium with the specific object of fitting German youth to rise above Napoleonic domination. The battles of Leipzig and Waterloo came too soon after he had begun this self-imposed mission, however, for his work to have had much influence. In Sweden, Per Henrik Ling (1776-1839) added to and modified the classical exercises to produce the routine that we know as Swedish gymnastics today. Gymnastics was first taught in America in 1825 by Charles Follen and Charles Beck, who were pupils of Jahn. Dio Lewis created a vogue for light exercise with rings, dumbbells, and bar bells between 1860 and 1870. In 1879 the Hemenway gymnasium opened at Harvard with Dudley Sargent's apparatus, and in 1889 Nils Posse introduced the Swedish system of gymnastics to this country and the Boston Normal School of Gymnastics was founded. The integration of gymnastics into the educational program was signalized by the first appearance of the term "physical education" in 1880. The International Gymnastic Federation with representation from Europe and the United States was founded in 1881, but it was not until 1923 that a complementary federation of educative gymnastics was organized. This may have been due to the fact that in France and Germany physical training by gymnastics remained under state control.

Rebirth of Olympic Games

During the 19th century, regularly scheduled athletic and gymnastic meetings began to appear. The German Turnvereine derived from the Turnhalle gymnasium of Jahn. The first regularly organized athletic meeting of modern times in England was held at the Royal Military Academy in Woolrich in 1849. Organized meetings and the growth of athletic clubs called for larger federations to regulate them. The Amateur Athletic Union was formed in the United States in 1888, eventually creating order out of chaos. This association established the pattern for the modern Olympic organization.

The man who was responsible for the modern revival of the Olympic Games in 1896, Pierre de Coubertin of France, was not an athlete himself and had no particular interest in the effect of athletics on the development of physique. He conceived of the idea of the games as a revolution in education that would employ sport as a medium. As a young man he had pondered the question as to why the small island of England could produce leaders who could and did dominate such a large area of the world, producing such tremendous wealth and influence for the mother country. He thought that he found the answer in the English public school system, which recreated the adult world in miniature with its own class system, the struggles and injustices, and the great emphasis on athletics as part of the curriculum. If only, he thought, every country in the world could have the incentive to train its youth in the keen struggle of international athletic competition, the same success might result in the development of their characters. Perhaps we might call this a sort of preventive psychosomatic medicine.

Many have since argued that the games should be discontinued because the disputes with which they are frequently marred are not conducive to international amity. It was never the intention of the founder that they should be. In London over 40 years ago Coubertin made the following statement after a particularly violent series of incidents in the 1908 Olympic Games:

> Heaven preserve us from a society in which there are no excesses and where any expression of impassioned feeling must be kept imprisoned within the narrow confines of convention . . . . When I think of the attacks without number to which [the International Olympic Committee] has been subjected—the ambuscades, the unbelievable conspiracies, the mad jealousies. . . . I thrill to the realization that this sort of wrestling is great sport, even when our adversaries disregard the niceties of the classic techniques and go in for catch-as-catch-can methods. The important thing in life is not the victory, but the struggle; the essential thing is not to have conquered but to have fought well. To spread these precepts is to develop a more valiant, more strong, more scrupulous and more generous humanity.

The leading amateur athletic governing bodies from each country that had them were invited to send representatives to form the new Olympic organization. Many difficulties lay or were placed in the way of its success, but the doughty founder persisted and within three years the first Olympiad of the new series was held at Athens in 1896 with nine countries sending contestants. Under the new rules there was to be no age limit for competitors. The following events must be included in every Olympic competition: athletics (which by now had come to mean what we refer to in the United States as track and field and cross-country), gymnastics, boxing, fencing, shooting, wrestling, rowing, swimming, equestrian events, the modern pentathlon (running, riding, shooting, swimming, and fencing), cycling, weight-lifting, yachting, and competition in the fine arts (music, literature, art, sculpture, and architecture). Optional events have included soccer football, Rugby, polo, water polo, field hockey, handball, basketball, canoeing, and gliding. Other events such as tennis and archery have been included as demonstrations and then discontinued. In order to be eligible for inclusion in the Olympic program a sport must be practiced in at least 10 different countries, and at least 6 countries must indicate that they will enter contestants. Women appeared for the first time as competitors in swimming and diving events at Stockholm in 1912.

It is to be noted that the games are awarded by the Olympic Committee not to countries, but to individual cities. The second games were held in Paris. France, in 1900; the third in 1904 at St. Louis; 1906 at Athens, Greece, (a two-year interpolation not regarded as entirely official); 1908 at London, England; and 1912 at Stockholm, Sweden. War prevented holding of the games in 1916, but in a remarkable recovery Antwerp, Belgium, staged the games in 1920 to resume the series. Subsequent games were held at Paris in 1924; Amsterdam, Holland, in 1928; Los Angeles in 1932; and Berlin, Germany, in 1936. This time war interrupted the series for 12 years until London, in an unusual demonstration of courage and organizing ability, staged the games in 1948. Helsinki, Finland, carried on in 1952; this year the games go to Melbourne, Australia, and in 1960 will return to Europe to be held in Rome, Italy. A series of games to include only winter sports was inaugurated at Chamonix. France, in 1924 and has since been held at St. Moritz, Switzerland, in 1928; Lake Placid, N. Y., in 1932; Garmisch-Partenkirchen, Germany, in 1936; St. Moritz in 1948; Oslo, Norway, in 1952; and Cortina, Italy, in 1956. In 1960 the winter games will be held in Squaw Valley, Calif. Events that are currently part of the winter program are bobsledding (two-man and four-man), figure skating for men and women (individual and pairs), cross-country skiing (10 km. and 15 km. relay for women; 15, 30, 40, and 50 km. relay for men), downhill slalom and giant slalom skiing for men and women, ski jumping and Nordic combined (jumping and downhill skiing) for men only, speed skating (500, 1,500, 5,000 and 10,000 m. for men), and ice hockey.

At the early Greek games the winner was awarded a laurel wreath. Today he gets a gold medal. Silver and bronze medals are given for second and third places and certificates for fourth, fifth, and sixth places. Four hundred eighty-four competitors appeared at Athens in 1896 and most of them paid their own way. By the time of the games in Amsterdam in 1928, this number had increased to almost 4,000. Although only 1,700 contestants made the trip to Los Angeles in 1932, it was there that the construction of an Olympic village, especially built to house them, was introduced. This has now fortunately become a regular part of the program, since about 6,000 entered for the games in London in 1948 and more may be expected in Rome in 1960.

The fact that the games have maintained their amateur standing is best indicated by the disputes concerning professionalism that have arisen before and after each games. These disputes, although celebrated, are remarkable by being so few in number, indicating the strong hand that has been held by the Olympic Committee under the presidency of Baron de Coubertin and his successors. Americans will best remember the charges against the famous American Indian athlete, Jim Thorpe, who had startled the world by his remarkable performance in winning the decathlon at Stockholm in 1912. He had to return his medals and certificates, and his records were erased from the books. For some reason, long distance runners have been frequently involved in these disputes, and this year's case of Wes Santee serves to recall similar difficulties involving Paavo Nurmi of Finland and Jules Ladoumegue of France.

The current discussion as to whether the Russian teams should be considered professional, because they are subsidized by the state and because special considerations are given to athletes in training, has somehow missed the point, as Avery Brundage has pointed out. The International Olympic Committee has been preaching for 60 years the value of national programs of physical education and sports. The Russians are almost the only ones who have taken it seriously. Their athletes made such an outstanding showing in the Winter Olympic Games because as individuals they had trained hard and had entered their events in fine physical condition. The Olympic competition is an individual, not a national, matter.

Although there are team events in the various sports, there is no over-all team prize for the most events won or points scored by any particular country. The so-called unofficial point score for all events is strictly a product of newspaper manufacture, and the fact that the United States has more than once been adjudged the "victor" in this fashion is of absolutely no significance. All victories or outstanding performances are individual, no matter how much they may inflate national pride. No longer do we breach the walls of the city to receive home the Olympic victor as was once done in ancient Greece. Other honors are readily forthcoming, however, and the financial reward for the one who wishes to turn professional later may be, as in the case of some past skating champions, considerable.

U. S. Contributions

The United States has made some interesting and some outstanding contributions to the history of the modern games, among them the first winner to the modern series of Olympic games, who is still alive and active today at 87. He is James B. Connolly of Boston, who left Harvard and went with 11 other representatives from this country to win the hop, step, and jump championship at Athens in 1896. No other athlete has ever equaled the accomplishment of Ray C. Ewry of this country, who in four Olympic Games (1900, 1904, 1906, 1908) captured 10 gold medals in the standing high jump, broad jump, and hop, step, and jump events, which have since been discontinued. The outstanding individual performance recorded in the track and field events of one Olympic Games was turned in by Jesse Owens of the United States at Berlin in 1936, when he won gold medals in four events, the 100-m. and 200-m. dashes, 400-m. relay, and broad jump. His performance in each instance tied or broke or aided in breaking the Olympic record. These records have not since been exceeded in Olympic competition. No other athlete has ever exceeded his distance in the broad jump (26 ft. 5 5/16 in.) at any time except himself (26 ft. 8¼ in.). Bob Mathias is the only man ever to win the decathlon twice in the Olympic games (1948, 1952). In so doing he set a new record for points scored under the new system in his second try.

The current president of the International Olympic Committee is the first man from the United States elected to this important office. He is Avery Brundage, a formidable athlete in his own day, although never an Olympic victor, since he achieved his peak performances during World War I when no games were held. He won the United States all-around track championship in 1914, 1916, and 1918. This achievement is best measured by considering that this series of events required as much, if not more, skill and endurance than the Olympic decathlon and that they were all contested in one day rather than two days, as is the case in the decathlon.

Doctors and the Olympics

Physicians, both as graduates and as medical students, have won their share of victories at the Olympic Games. Probably the first to win the gold medal as a physician was G. E. Sheldon of the United States, who was springboard diving champion in 1904. An even more famous Olympic diving champion is Sammy Lee, an ophthalmologist in the U. S. Army Medical Corps, who won the high platform diving championship in 1948 and 1952. Also in the field of swimming, George Kojac of the United States, competing in the 1928 Olympics as a medical student, won the 100-m. backstroke, swam on the 800-m. relay team, and took fourth place in the 100-m. free style swim. In 1908 at London, J. R. Calkins of the United States was a member of the team that won the revolver and pistol-shooting titles at 50 and 100 yd. In 1932 at Los Angeles, John R. Huffman took sixth place in the saber event, an outstanding achievement in a sport so dominated by the Europeans. In 1952 Britton Chance of Philadelphia sailed his 5.5-m. yacht to victory at Helsinki.

Oddly enough, in track and field events, where one would least expect to see physicians or medical students as competitors because of the enormous amount of practice required, they have achieved some noteworthy performances. Paul Martin of Switzerland took second place in a thrilling 800-m. race at Paris in 1924 while he was a medical student. Patrick O'Callahan, now of Roseville, Ireland, won the Olympic hammer throw in 1928 and 1932. In 1936 John Lovelock of New Zealand, who was also holder of the world's outdoor records at one mile and 1,500 m., won the 1,500-m. race at Berlin. In 1948, Arthur Wint, a medical student from Jamaica, British West Indies, won the Olympic 400-m. crown.

As medical training and practice become more complex and demanding of time, we can expect to see fewer names of physicians as competitors and many less as victors in the Olympic Games. At the same time, the growing interest in the relationship between medical and physiological problems and athletic performances, which has led to the establishment of the International Federation for Sports Medicine, British Medical Sports Association, and the American College of Sports Medicine, assures us that there will be increasing participation of physicians as coaches, trainers, advisors and observers. Such distinguished sports buffs as Adolphe Abrams, medical advisor to Great Britain's Olympic teams for many years, may expect to be joined by many others who contribute their skill and knowledge as well as their enthusiasm to these international programs.

Even those physicians who have mental reserves about the medical value of sports, particularly athletics, may wish to ponder the effect in safeguarding mental health that might be produced if they could succeed in inculcating the qualities that at least one writer feels that they are capable of promoting:

> Loyalty that excludes taking refuge in subterfuges, docility and obedience to the wise commands of the director charged with the training of the team, the spirit of self-renunciation when one has to fade into the background in order that the interests of the team may thereby be furthered, fidelity to obligations undertaken, modesty in victory, sereness in adverse fortune, patience toward spectators who are not always moderate, justice if the competitive sport is bound up with financial interests resultant from voluntary agreements, and, in general, chastity and temperance already recomended by the ancients themselves.

These and other remarks were addressed to the Italian Sports Federation on the 10th anniversary of its revival last year by Pope Pius XII, who was an enthusiastic and skillful rider and swimmer as a young man and who was responsible for the installation of a gymnasium at the Vatican. Substance has already been lent to these words by the sportsman-like conduct of the many Olympic competitors from all over the world and their subsequent records as good citizens as well as good sportsmen. This year has already seen the great mile champion, John Landy of Australia, stop in the middle of an Olympic trial race to help a fallen competitor at the risk of losing his own place on the team. No one who was present at the opening of the Olympic Games in Helsinki in 1952 could ever forget the tremendous inspiration of that moment when the carefully guarded secret of the identity of the runner to bring the Olympic torch into the stadium was revealed. The incomparable Paavo Nurmi appeared in running clothes and circled the track before lighting the fire, while the huge crowd rose as one with a mighty roar of pride in this man who had so well exemplified their athletic ideal to the world in previous Olympic contests.

The interest and affection in which the Olympic games are held by such a great number of the world's people, and the strength that has enabled them to overcome the jealousies, bickering, and unfortunate occurrences that at first almost prevented their rebirth and later have at times marked their growth, is best epitomized in the Olympic Oath taken by all competitors at the start of the games. If all of our interest and activities in sports from the very beginning had produced nothing more than the desire to implement this oath, then it would have all been worthwhile. "We swear that we will take part in the Olympic Games in loyal competition, respecting the regulations which govern them and desirous of participating in them in the true spirit of sportsmanship for the honor of our country and for the glory of sport."

147 W. Main St.

THE INTERNATIONAL FEDERATION FOR SPORTS MEDICINE

Giuseppe La Cava, Rome, Italy

• *The Fédération Internationale Médico-Sportive (FIMS) first convened in 1928, when 33 physicians from 11 countries met in connection with the Winter Olympic Games. The organization has continued in spite of interruption by World War II. Its purpose has been to inaugurate relevant scientific research, to promote the study of medical problems encountered in sports and physical exercise, and to organize international congresses to be held simultaneously with the Olympic Games. The 11th International Congress was held this year in Luxembourg. The list of topics discussed in the past includes such problems as standard charts for examination and evaluation of athletes, tests of physical fitness, medical guidance in physical exercise, therapeutic exercise, orthopedics and traumatism, evaluation of physical education training, women in sports, and young people in competitive athletics. The FIMS has also been able to help with the organization of occasional scientific meetings and national conventions when help was needed by the organizing committees in various countries. In 1954 there were 23 national associations concerned with the diffusion of the concept of medicine related to sports.*

Physicians of different nations, guided by a common goal, that sports were to be a means of improving the health of mankind as a whole, met for discussion and soon formulated the idea of establishing a unique organization. Thus, the first medical congress dedicated to sports took place in March, 1915, in Paris. The topics it treated were the physiology of physical exercises and kinesitherapy. However, this good start was interrupted by World War I, which put an end to peaceful international relations. After World War I, when the Olympic Games were reestablished and the scope of their organization was enlarged, the sports physicians no longer limited their activity to the treatment of sick athletes and to emergency calls but began to engage in scientific reasearch and systematic tests on the finest champions of the world.

Organization and Purposes of Federation

On Feb. 14, 1928, at the time of the ninth Olympic Games, the first step in the founding of the Fédération Internationale Médico-Sportive (FIMS) was taken. On this occasion, in St. Moritz, Switzerland, where the Winter Olympic Games were being held, the first meeting of physicians took place; 33 physicians of 11 different nations participated. W. Knoll (Switzerland) was elected president; A. Mallwitz (Germany) secretary general; and F. J. J. Buytendijk (Holland), W. Dybowski (Poland), and Latarjet (France) members. Buytendijk was put in charge of the organization of the first International Congress on Sports Medicine, scheduled to take place in Amsterdam, the Netherlands, during the Summer Olympic Games in the month of August of the same year. The congress met with great success; 281 physicians and specialists in physical education, representing 20 different nations, were present. The first constitution of the Association Internationale Médico-Sportive (AIMS) was approved. Buytendijk was elected president. The constitution of the association contained the following purposes: (1) to inaugurate scientific research on biology, psychology, and sociology in their relation to sports; (2) to promote the study of medical problems encountered in physical exercises and in sports, to be done in collaboration with various sports federa-

Director, National Institute for Sports Medicine, and Orthopedic Surgeon, Rivniti Hospital.

tions and organizations; and (3) to organize international congresses to be held simultaneously with the Olympic Games.

In October, 1930, the committee of the association, meeting at Vienna, Austria, chose Brown of New York to take charge of the second congress. The congress was scheduled for the time of the 10th Olympic Games, which were to be held in Los Angeles in 1932. This congress, however, did not take place, because the American physicians did not participate in the program planned by their European colleagues. The second convention, therefore, did not take place until September, 1933, when it was held at Turin, Italy. In the meantime Buytendijk had resigned, and Latarjet of Lyons, France, had been elected president. The topics to be discussed were divided according to subjects and grouped under nine headings, including anthropology and charts for evaluating physical fitness, organization of physical directors of different nations, kidneys and sports, respiration, fatigue, orthopedics and traumatism, and women and sports. It was on this occasion that an international association, with Latarjet as president, can be considered to have been duly established; the second article of the constitution was changed and the name of the association was changed to Fédération Internationale Médico-Sportive et Scientifique. It was also established that the general assembly was to meet every four years when the congresses were held. Congresses were to be organized at the time of the Olympic Games. Later this interval of four years was recognized as being too long.

For this reason French doctors interested in sports organized at Chamonix, France, in September, 1934, the third International Congress on Sports Medicine; eight different nations were represented. The following topics were discussed: issuance of a standard chart for medical evaluation of physical fitness, medical control of physical education and of sports, medical guidance in physical exercises, and sports engaged in at high altitudes.

At the same time the *International Bulletin* was established and new proposals were advanced, for instance, the teaching of physical education in all medical schools, with practical and theoretical lessons and final examinations; the awarding of a special diploma to those passing these examinations, enabling them to obtain positions such as those of hygienist and school doctor; the institution of a national and international licensing system for athletes with the approval of the associations for sports medicine of various countries (without such a license, the athletes were not to be allowed to participate in any international contest); and the standardization of medical diagnostic forms (minimal and maximal). Other changes were made in the constitution. The word scientific was eliminated from the name of the federation; article 11 of the constitution provided that the federation must meet at the same time and collaborate with the section on hygiene of the League of Nations.

The fourth International Congress on Sports Medicine was held during the 11th Olympic Games in 1936 in Berlin, Germany; 1,500 physicians of 40 nations met July 28 to 31. The topics, divided under nine headings and discussed in six different meetings, were metabolism and circulation; circulation and respiration; metabolism, training, and hygiene; psychology in sports; aviation medicine; medicine of physical education; traumatology and medical gymnastics, biometrics; and biological and social medicine.

The following year the French again organized an international congress, the fifth, which was held July 11-17, 1937. The topics discussed were divided into four categories: biology and sports, scholastic and postscholastic education, orientation in sports, and accidents in sports. At this congress, Latarjet and Knoll were elected honorary presidents, Conti (Germany) was elected president, Ugo Cassinis (Italy) secretary, and Albert Govaerts (Belgium) treasurer. The last convention prior to World War II was held in Brussels, Belgium, on July 9-12, 1939. The principal topic of discussion was biology applied to physical education and to sports; at this congress the number of the members of the committee was increased with the election of Paul A. Chailley-Bert (France), Hermann Brandt (Switzerland), Biezius (Lithuania), Plasch(Belgium), Dybowski (Poland), Emerich Szukovathy (Hungary), and Jiri Kral (Czechoslovakia). The organization of the seventh International Congress, which was supposed to take place in 1940 in Finland, was entrusted to Simo Antero Brofeldt of Helsinki. This congress never took place, because in the meantime World War II had begun.

Postwar Changes

After the war, Govaerts of Brussels, Belgium, the last vice-president of the federation, acting in accordance with the rules and regulations of the constitution approved in 1939, took the initiative and entrusted Kral of Prague, Czechoslovakia, with the duties of secretary general. The members of the committee, Chailley-Bert, Louis Merklen, Kral, B. A. McSwiney and Brandt, consented to a democratic reorganization of the federation. The new constitution was approved by the general assembly, which gathered in Brussels on June 21, 1947.

The seventh International Congress was held in Prague in 1948. At that time the wounds of the war were still open and bleeding. The spirits of all Europeans were still shaken; Europe itself was slowly recovering from the ruins of the war. Slowly the federation picked up, one after another, the threads of its web, which had been torn apart by the war. The congresses, which since that time have taken place successfully every two years, have become the foundation stones on which the magnificent edifice of modern sports medicine is developing. The eighth International Congress met in Montecatini, Florence, Italy, in 1950. It established the structural foundations of the new organization, giving it that democratic and universal spirit that has stimulated and determined the formation of many national associations for sports medicine. At this Congress the following topics were treated: physical education training and its evaluation, sports competition among young people, and reeducation of "traumatized" athletes. Govaerts was reelected president and I was elected secretary general. The ninth Congress took place at the Sorbonne in Paris, France, May 30-June 1, 1952; it demonstrated the high scientific level of the work and studies that had been carried on. The topics of the congress were surgical and nonsurgical treatment of traumatic lesions of the knee (fractures excluded) and the general syndrome of adaptation in sport activities.

The 10th International Congress in Belgrade, Yugoslavia, in 1954, in which a large number of legally represented national associations participated, gave proof of the solidarity so far attained by the federation. The topics treated were sport in mature age and sport and physical rehabilitation.

The 11th International Congress, which recently took place in Luxembourg on May 30-June 1, again confirmed the fundamentally scientific and moral aspect of the branch of medicine that deals with sports. Sports medicine, as a discipline, has gained autonomy among the medical and biological sciences. At this last congress, the following topics were discussed: lesions of the muscles and of the tendons and standardization of the cardiofunctional tests in sports.

At present the executive committee of the federation is composed of Chailley-Bert (Paris), honorary president; A Govaerts (Belgium), president; G. La Cava (Rome), executive secretary; Kral (Prague) vice-president; Tegner (London), vice-president; Jones (Luxembourg), treasurer; and Kriatchko (U.S.S.R.), Koch (Germany), Prokop (Austria), and Smodlaka (Yugoslavia), members.

Recent Activities

In recent years the activities of the federation have followed two essential directions. The first is concerned with the progress of the studies made by that branch of medicine that is related to sports. The federation has sponsored scientific meetings and national conventions; it has encouraged worthwhile undertakings and has given help for their successful realization whenever this was needed by the organizing committees. We must remember, among other meetings of international character, the successful Argentine Congress for Sports Medicine, which took place in Buenos Aires; the symposium held in Berne, Switzerland, on the occasion of the European athletic contests; the congresses of the German Association for Sports Medicine held at Edenkoben, Augsburg, and Freudenstadt; the scientific meetings of the British Association for Sports Medicine; the courses on sports medicine held in different nations, as in Austria, Yugoslavia, and Switzerland; the national Italian congresses of Trieste and Perugia; the international meetings of Turin, Italy, on the occasion of the European swimming championship; of Cortina, Italy, on the occasion of the seventh Winter Olympic Games; and of Sestriere, Italy, dedicated to winter sports; the meetings of the Commission on Sports Pedagogy of the European Center for Culture in Geneva, Switzerland; and the convention on sports medicine organized by the Ministry of Physical Education and Sports of Luxembourg.

The initiative of the Italian Federation for Sports Medicine is also to be pointed out. This federation publishes every two years an international bibliography that brings together everything in the field of sports medicine that is published in the world. The same can be said also for the journal *Medicinea Sportiva,* which each month publishes the international federation's *International Bulletin.* This journal. together with many other specialized publications dealing with medicine relating to sports—French, German, Belgian, Yugoslavian, and Argentine—keeps alive in the members of the federation the spark that kindles the fire of scientific and clinical research and works for the solution of the important moral, social. and educational problems connected with the development of sports in the modern world.

The second is concerned with the diffusion of the concept of medicine related to sports and with the propaganda for the establishment of national associations in different countries. The results have been very good. While in 1950 in Montecatini there were only 6 such regular associations, in 1952 the number went up to 13 and in 1954 to 23, and with the recent admission of Australia, Bulgaria, Chile, and Rumania and the eventual admission of Canada, Poland, and Hungary, the number of national associations will go up to 30. This undoubtedly makes for success, yet it is not to be considered as a point of arrival but rather as a stage in the establishment of national associations in all countries where sports and physical education are practiced.

The task of spreading the concept of sports medicine was greatly helped by the official recognition of the federation received in Oslo, Norway, in 1952 from the International Committee on Olympic Games. The high prestige of the committee was especially stimulating and helpful to the efforts of the federation in establishing relations among international sports federations. A very detailed program along these lines was recently proposed by the general assembly of the federation on the occasion of the 11th International Congress in Luxembourg; its fundamental points are (1) participation of a medical representation or a medical commission in each international sports federation and (2) the establishment of a technical committee in the FIMS composed of the abovementioned medical representatives for the coordination of the sports and medical activities. A direct liaison between sports federations and the international federation would thus be feasible through the most qualified representatives. The federation could accomplish its duty as a unique specific consultative body in the field of sports medicine recognized by the International Olympic Committee. This general program has been outlined by the president of the committee, Avery Brundage, whom we thank for the interest and good will with which he follows our work. The good results that have already been obtained by some federations like the International Association of Amateur Boxing and the efforts made by other associations (of athletics in general and of swimming) hold out hope for the definitive completion of this program and for the realization of those objective ideals that modern sports medicine has encouraged by its spontaneous, vital initiative.

A MEDICAL HISTORY OF GYMNASTICS

Allan J. Ryan, Meriden, Conn.

• The medical profession has always been interested in exercise, not only for recreation and as an aid to physical development but also as a prevention against disease. This article introduces a modified symposium on athletics both as sport and for the furtherment of health.

The history of physical exercise, especially when reviewed in a medical vein, reveals the logic behind gymnastics as part of the curriculum to strengthen the entire body. Much of physical exercise as we know it today has been, and still is, formulated by the physician, on the basis of sound medical principles.

The history of man's interest in voluntary coordinated exercise of all sorts from the most ancient recorded history to modern times is embodied in the study of the origin and development of gymnastics. This word of Greek origin derives from the circumstance that the competitors exercised naked. Hence, their place of exercise became the gymnasium, a public building, as opposed to the palaestra, a private school where boys were trained in physical exercise. An athlete in ancient Greece was originally one who contended for a prize in the Olympic Games, whether in musical, gymnastic, equestrian, or other competition. Later, only those who competed in the gymnastic contests were designated athletes. The story of the development of gymnastics is also the story of the interest of doctors of medicine in exercises designed not only for recreation but also to aid in physical development as a preventive of, or countermeasure to, disease.

This story has been summarized succinctly in a series of articles written by Ludwig H. Joseph, M.D., and published under the title "A Medical History of Gymnastics" in *Ciba Symposia*, March-April, 1949. With the permission of the editors of that magazine, these articles have been condensed into one and are presented here with a group of essays that signalize the continued interest of the medical profession in sport and athletics of all kinds.

Gymnastics from the Middle Ages to the 18th Century

Since its origin in antiquity, the concept of gymnastics has not been uniform. Educational and medical gymnastics were already known to the Greeks. Generally speaking, all definitions of gymnastics can be reduced to two: first, that every intensified movement is gymnastic exercise (Oribasius of Pergamon, 326-403 A.D.); and, second, that in each exercise there is the idea of active volition (Galen and Avicenna). The concept of medical gymnastics included all healthful and health-furthering exercises. For this reason physicians at all times advised the avoidance of any exaggerated activity, particularly professional athletics. The concept includes both preventive and therapeutic gymnastics, the latter including gymnastics for the sick, weak, and elderly. Herodicus (fifth century B.C.) was reproached by Hippocrates for treating patients with fever by gymnastics. Asclepiades (128-68 B.C.) used gymnastics in connection with massage and dietetics.

The Early Middle Ages.—During the Middle Ages, the gymnastic practices of the classic Greco-Roman era were forgotten, but the idea of curative gymnastics was not entirely lost in medical circles. The first medieval health book, "Regimen Sanitatis Salernitanum," twice mentioned exercises as therapeutic measures. The governing feudal class was obliged to care for the physical education of its members who, for the most part, were soldiers. A boy's physical education began at 14 with vigorous sports and exercises, including dancing, and the most important premilitary exercise was horsemanship. The exercises of the medieval nobleman were the seven mentioned in the "Mirror of Knights": (1) riding with rapid mounting and dismounting; (2) swimming and diving; (3) shooting with the bow and crossbow; (4) climbing on ropes, poles, and ladders; (5) fencing, wrestling, pushing stones, and jumping; (6) dancing; and (7) tournaments. The ordinary citizens and craftsmen also applied themselves to the first six varieties. Acrobatics by professional performers were a principal form of entertainment.

The Renaissance.—Classic gymnastics revived with the Renaissance and the rediscovery of Greek and Roman literature. With their increasing study, educational theory tried to achieve the aim of classical education: the man of vigor and wisdom. For this reason, the great teachers of humanism consciously introduced gymnastics into their educational program. Petrarch (1304-1374) in his pamphlet, "Against a Certain Physician," expressed the idea of substituting a natural therapy, such as exercise, for medical remedies that poison the body. Vittorino Da Feltre (1378-1446) made gymnastics obligatory in his educational program. In addition to his knowledge of medicine, he was learned in philosophy, science, mathematics, Latin, and Greek. Under the patronage of the Duke of Mantua he founded an educational institute in the country for children of the nobility and the poorer classes as well, where physical education preceded intellectual training. He selected for each student a type of exercise especially suited for his body, his age, the season, and the time of day. He was especially proud of the fact that he succeeded in changing the bodily constitution completely by means of special exercises in connection with dietetics. In general the exercises employed were riding, fencing, swimming, dancing, wrestling, running, jumping, archery, throwing the discus, ball games, hunting, fishing, and mock battles between two parties. All the games were played outdoors in both summer and winter. Vittorino left no writings, but his doctrine changed the spirit of all later education completely. This doctrine had the purpose of bringing to the highest perfection the three essential elements of man: body, mind, and soul. The introduction of gymnastics into the educational program was considered an indispensable preliminary condition for educational success.

Cardinal Aeneas Sylvius Piccolomini, later Pope Pius II (1404-1464), inveighed against the decay of the physical education that ought to precede spiritual education. For hardening purposes he recommended life in the country from time to time, physical work in the open air, and plain food. He considered hunting a sport especially suitable for physical education, since it is connected with a considerable number of exercises, such as riding, climbing, swimming, shooting with the bow, and hurling the spear, as well as hardening against the effects of weather. Francesco Barbaro (1395-1440) considered not only the spiritual but also the physical condition of both parents as highly important for the health of their child and therefore recommended physical exercise for young women too. Parents were also interested in play for their children so as to attain a healthy development of the body. Leon Battista Alberti (1404-1472) called special attention to physical exercise as of the highest importance even in early infancy. He recognized that thus the muscles are strengthened, the nerves become accustomed to strain, the blood circulates more quickly; in short, the whole physical being becomes more lively. In the daily plan of studies of Duke Philibert of Savoy prepared by Philelphus, a peripatetic teacher, two hours for gymnastics and games were allowed, including running, softball, and football. Florentine football was played in the principal square of the city in a sort of stockade by two bands of youths selected from honored soldiers, gentlemen, seigneurs, and princes. According to Bardi, "a good player should play his game with easy and sprightly grace, in the which he will easily succeed if he proceeds in all his actions with moderation and without passion."

Maffeus Vegius (1407-1458) in his book, "Education of Children and Their Good Habits," distinguished strictly two sorts of exercises: those that serve as recreation from intellectual work, and those whose purpose is the strengthening of the body. The former should be of a lighter nature; the others, including military exercises, require greater efforts. He wished to avoid heavy athletics, suggested moderation in all actions, and rejected exaggerated exercises. Juan Luis Vives (1492-1540) in the fourth book of his work, "On Instruction and on Christian Education," stressed exercise as indispensable for young students. He proposed long, rapid walks, running, jumping, and throwing the discus. He emphasized expressly that all exercises must be executed not in a military but rather in an educational manner; that they are not to be carried on to such a degree as to produce intellectual fatigue; and that, on the contrary, they should refresh the young men and stimulate them to new intellectual power.

Medical Gymnastics in the 16th and 17th Centuries

The humanistic educators had linked gymnastics so closely with education in general that it was no longer possible to eliminate it from the educational program. But their doctrines did not fructify the medical discipline, because medicine was still highly dogmatic and scholastic during this period. Physicians in the 15th century were skeptical about the use of gymnastics. Generally, it is characteristic of the position of medicine during the Renaissance that it did little to advance gymnastics, recommending only the lightest exercise. The great changes in culture and mode of life at the end of the 15th century and the beginning of the 16th century marked the end of the Middle Ages. Although the original Greek documents on medical subjects were brought to light in the 15th century, the results of their study appeared only gradually. On the other hand, such inventions as gunpowder and the art of printing produced an effect on the people of that period as revolutionary as the discovery of atomic energy today. The art of printing made possible criticism and interpretation of the classical writings in a new sense and facilitated the propagation of such knowledge in larger scientific circles than ever before. Moreover, a general fever of inquiry seized many physicians.

Influence of Mercurialis.—Hieronymus Mercurialis (1530-1606), with his "Six Books on the Art of Gymnastics," stood as sponsor to medical gymnastics. Characteristic of this work is the fact that every exercise is considered from the viewpoint of its usefulness to health, since he considered all gymnastics of only medical value. For him, the only exercises of interest to physicians are those characterized by introduction of the conscious will, and particularly by strenuous breathing and vehement movement. Mercurialis classified gymnastics into two kinds, corresponding to kinds of medicine, preventive (or conservative) and therapeutic gymnastics. Conservative gymnastics is for the healthy, therapeutic gymnastics for the sick. In the first place, the quality and the quantity of exercise should be accommodated to each constitution. Preventive and curative gymnastics both make use of a purely physiological remedy, movement. On the contrary, drugs, especially the medieval medicaments, poisoned and weakened the body. Based upon the Hippocratic definition of health as harmony of the humours, the aim of every healthy exercise is to maintain this harmony. Strenuous military exercises are therefore not always suitable, even for healthy bodies. Athletics is indirectly injurious to health. These injuries arise from defective nutrition associated with training, namely, excessive meat-eating; from suppression of normal sexual life; and from the effect on the lungs of dust inhaled in the arena.

Mercurialis set up the following principles for medical gymnastics: 1. Each exercise should preserve the existent normal healthy state. 2. Exercise should not disturb the harmony between the principal humours. 3. Each exercise should be suited to certain fixed parts of the body. 4. All healthy people must be interested in gymnastics and regular exercise. 5. Sick people are permitted only such exercises as do not exacerbate the existing condition of the patient; exact diagnosis must be the basis for such individualized treatment. 6. Convalescents and weak and older persons should have special exercises. 7. Persons who lead a sedentary life, as well as scientists and prisoners, urgently need gymnastics. For medical gymnastics he thought that spring and autumn are particularly suitable, and the winter even more, for vigorous exercises. In the summer months the early morning, in the winter the later hours of the morning are to be preferred for exercise. Such activity should always be carried on in the open air in a place sheltered from the wind. It is good to clean the body thoroughly, even to take a purge before exercise, but exercise on an empty stomach is to be avoided. Gymnastics should strengthen not only the muscles but also the nerves, and should further sleep. According to Mercurialis, ball games strengthen the arms, the back, and the intercostal muscles and, therefore, are fit for convalescents, weak persons, and even for wet-nurses and epileptics. He discusses other kinds of exercise. Thus he distinguishes three sorts of walking: walking to and fro, in the sense of the Greek peripatetics, in order to stimulate intellectual conversation; then, more intensive walking, to aid digestion or to work up an appetite; finally, mountain climbing, because it is diaphoretic, to alleviate paralysis of the legs.

Merculialis considered running a very healthy exercise, when performed without carrying a burden and not over hurdles, and he thought running at night particularly healthy, because the body does not suffer the heat of the sun. This exercise strengthens the muscles and also the digestion. He recommended throwing the discus for the wrists of arthritic patients, especially, and for strengthening of the muscles of the legs, arms, hips, and back. Jumping he considered suitable for both sexes, though contraindicated for patients with pulmonary disease and pregnant women. Jumping with dumb-bells to increase the swing he considered unhealthy. Accompanied by music, gymnastics has a calming effect on the nerves. Athletic exercises, including hand springs, are to be rejected, as these push the intestines against the diaphragm. Only rope climbing and wrestling are wholesome. Very interesting, from the medical viewpoint, is the recommendation of passive gymnastics for patients confined to bed for a long time. This was to be achieved through the use of swinging beds, like hammocks. Like some modern physicians, he included in his work exercises of the voice, respiration, and even the eyes. Passive movements of the body on board ship, connected with the psychological effect of changing surroundings, Mercurialis considered wholesome for diseases of the lungs, larynx, and skin, as well as for headaches.

Followers of Mercurialis.—All books on gymnastics of the next centuries are based on this standard work of Mercurialis. The most original work after him in the field of gymnastics is devoted specifically to a single exercise, jumping. Entitled "Three Dialogues on the Acrobatics of Jumping by Saint Archange Tuccaro" (born about 1535), it mentions 53 varieties of jumping. Tuccaro tried to make the body flexible in youth. Although not a physician, he pointed out the medical benefit to be derived from this exercise. "This robust and strong exercise has a tendency to expel excrements and to calm all sorts of humours." Ambroise Paré (1510-1590), the famous surgeon, dealt in detail with movement and repose in the introduction to his "Surgery." He referred to the doctrine of Galen that the body needs exercise for health. In accordance with the theory of the humours, he reserved heavy exercise for large, cold-humoured persons, lighter exercise for thin and temperate ones. As did Mercurialis, he included breathing exercises and massage in gymnastics. Moderate exercise was to be taken before meals to help the digestion. Oddly enough, Paré added carrying of burdens to the usual exercises, such as running and riding. Not only did he consider gymnastics a part of general hygiene but, as a surgeon, he felt that exercise of the limbs, especially after fractures, was indispensable. He suggested light exercises for diseases of the kidney and bladder and for gout.

Joseph Duchesne (born 1544), who was physician to the court of Henry IV of France, wrote on exercise in his "Ars Medica Hermetica": "The essential purpose of gymnastics for the body is its deliverance from superfluous humours, the regulation of digestion, the strengthening of the heart and the joints, the opening of the pores of the skin, and the stronger circulation of blood in the lungs by strenuous breathing." Here, for the first time, we find swimming included on an equal basis with other exercises. It is contraindicated in cases of melancholy and diseases of the lungs but is considered as generally strengthening the body. Walking is recommended, particularly for those older persons who were formerly accustomed to more strenuous exercises. In his "Gymnastic Exercises," Laurent Joubert (1529-1583) attached great importance to daily exercises. As professor of medicine of the University of Montpellier, he was occupied particularly with the problem of introducing gymnastics and its use into the medical course. He considered physicians the only ones capable of prescribing gymnastics, rather than teachers and educators, whom he regarded as insufficiently educated. In the second book of Marsilius Cagnatus' "Preservation of Health," published at Padua in 1605, rowing is introduced into medical gymnastics for the first time.

Physiology and Gymnastics.—Physiology gave gymnastics a scientific basis, liberating it from empiricism. Sanctorius Sanctorius (1561-1636), physician of Padua, was first to study scientifically the body during perspiration. Attendant upon the progress of mechanics, there developed an increasing interest in human and animal movement. The literature on this subject began with Jean Canappe's short essay, "The Movements of the Muscles," published in 1546. The great progress in the physiology of the muscles continued into the 17th century. Many medical works covered this subject, for instance, Claude Perrault's "Mechanics of Animals" (1680), Ulisse Aldrovandi's "On Quadrupeds," Fabricius ab Acquapendente's "Movement of Animals" (1614), and the book on animal movements by Antoine Deusing (1612-1666). Girolamo Cardano's (1501-1576) theory of the movement of the muscles is conceived entirely from a mathematical-mechanical standpoint. He himself practiced gymnastics daily. He recommended light exercise for pregnant women, swimming, but no exercise for older men.

Gymnastics in the Pre-Revolutionary 18th Century

The 18th century is characterized by the Enlightenment and the movement for a return to Nature. Representative of the Enlightenment is the great "Encyclopedia" of Diderot and D'Alembert. Volume 7 of the 1757 edition contains the following definition of gymnastics: "men acquire bodily force and agility by different means for different purposes." Military gymnastics arose from the need of men to assure their safety. Medical gymnastics arose from the need of men to take care of their health with suitable exercises ordered by physicians. Athletic gymnastics grew out of the desire to give public exhibitions of strength and agility. Regarding gymnastic medicine the dictionary adds: "medical gymnastics, although simple in origin, became too complicated in practice, and ended in an excess of luxury, effeminacy, and voluptuousness." The life of the upper classes was never as artificial as in this rococo period. It is especially remarkable, therefore, that, despite all such customs, even in these times, gymnastics did not disappear entirely from the educational program.

Nicolas Andry (1658-1747), professor of medicine at the Royal College of Paris, in his "Orthopédie" took an entirely new road. The word orthopedics was introduced to medicine by this author. The subtitle makes clear to us the purpose of the author: "the art of preventing and correcting the deformities of children's bodies." Andry advises parents to pay attention to the bodily development, even of infants. He recommends special exercises to obtain large flat collarbones and a well-shaped chest. These consist in stretching the arms with wands, lifting up a rope reaching to the ground, and holding the wand extended horizontally. The spine is to be made flexible by flexion over the lap or the knees. This exercise with the hands on the ground, made without any assistance, is known in gymnastic nomenclature as the bridge. In general, to prevent deformities or to cure present ones, Andry recommended exercise of the legs or the arms, with or without wands, carried out very energetically in case of paralysis or after fractures. While he recommended for the children of the upper classes such exercises as riding and hunting, for the poorer classes he proposed rural work as a substitute for gymnastics.

Sabbathier in 1772 deplored the bad habits of his time, urged moderate gymnastics for convalescent and weak persons, but rejected all athletic exercises as unhealthy. In England, Francis Fuller, in his "Gymnastic Medicine" of 1705, lamented the decay of physical education and medical gymnastics. In Germany, the physician Johan Zacharias Platner in his "Gymnastics of Antiquity" (1724) bitterly expressed the opinion that his time hardly appreciated healthy daily exercises and that all sense of the necessity of gymnastics to preserve a healthy body was lost. Joseph Tissot (1756-1826), a French military surgeon, called his work "Medical and Surgical Gymnastics" and described it as an essay on the usefulness of movement, on different exercises, and on repose in the cure of diseases. He said that moderate gymnastics gradually produced a lasting result but that, on the other hand, strongly exaggerated exercise was injurious to muscles and internal organs, through excessive wear and tear. Therapeutic gymnastics is indicated especially for rheumatism and gout. During convalescence from chronic diseases, he suggested slow and gradually increasing bed exercises. He proposed exercise even during convalescence from abdominal diseases. Gymnastics was to be supplemented by massage, especially before swimming, and by relaxation afterwards.

Giuseppe Nenci, professor of medicine at the University of Siena, in his "Discussion on Gymnastics with Regard to Its Use in Medical Practice" (1766) advocated curative gymnastics, which, in contrast to drugs and surgical therapy, is less energetic, particularly if used gradually and individually. Life and health consist in a continuous but equilibrated movement of fluids distributed into innumerable channels of the body. During this continuous movement, some parts are dispersed or must disappear entirely. Therefore, they must be supplied by others through alimentation. It is perspiration, on one hand, and a correct distribution of fluids, on the other, which leads the necessary introduction of new humours. Moreover, the alternating extension and contraction of the muscles extracts the blood from the veins of the heart and the lungs; in this way they facilitate the entrance of fresh blood into arteries. Therefore, gymnastics is the necessary precondition for the provision of blood to the whole body. Practically, this fact is manifested by an augmented diaphoresis and opening of the pores of the skin. This has a therapeutic effect on skin diseases, obesity, gout, and dropsy, which are characteristic diseases of blood stagnation. Nenci suggested light daily exercises for intellectual workers, older persons, and delicate women. Long walks or riding, which he considered the most natural exercises, are beneficial to both body and mind.

Summary

Looking at the development of gymnastics from the early Middle Ages on to the beginning of our modern era, one can see that, after the decay of antiquity, physical education had to be built up anew. The influence of classic gymnastics emerged only in the Renaissance. Seldom in the history of human culture has the intellectual climate been changed so consciously as in the epoch of Humanism and the Renaissance. The education of the Western European youth was based consciously on the Greek ideal of man, found anew in works of art, literature, and science. It was a natural consequence, therefore, that educational gymnastics appeared. Its aim—to harmonize intellectual and physical education, in which is included also the psychic influence of exercise—henceforth remains the basis of every successful educational program.

The medical use of gymnastics could be understood only in a period when medicine began to emancipate itself from the fetters of dogmatism. Just as the time was ripe for a Columbus to discover America, so it became mature for a Mercurialis to establish medical gymnastics, and to consider exercise only from a medical and hygienic standpoint. This medical appreciation was at first empirical. But at the end of the 17th century, stimulated by the progress of physiology, attempts were made to give to exercise a scientific basis. The 18th century provided social influences that showed new purposes for gymnastics. Orthopedic gymnastics arose from the unnatural clothing of this period and the deformities of the body connected with it. Orthopedic gymnastics leads directly to the Swedish gymnastics of our time. Thus medical gymnastics reached its definitive form in the period before the French Revolution.

PHYSICAL FITNESS FOR ALL

Robert J. H. Kiphuth, New Haven, Conn.

• *There is evidence of continued neglect of those activities whereby men and women should strive to maintain a healthful degree of physical strength, agility, and endurance. A lack of physical fitness limits one's opportunities for a full enjoyment of professional and personal life. Formal exercises can take the place, to some extent, of physical work. A planned program of exercises can be adapted to the individual's age, and, by progressing from a cautious beginning, it can be developed sufficiently to undo the mischief of long periods of neglect. The physical activity also results in certain mental satisfactions that make for a feeling of alertness and power. A set of exercises chosen from those herein described can increase the individual's ability to meet the day's physical and mental tasks.*

What is meant by physical fitness? Certainly, during the past year, that term has been uppermost in the minds of all Americans for many reasons. Coronary disease is prevalent in both men and women; statistics revealed by the Kraus-Weber experiments indicate the lack of fitness in the American boy and girl; the school programs of physical education fail to concentrate upon the physical development of all students and emphasize instead the few who are well-skilled in athletics; and the American people continue to prefer being spectators instead of participants in sports. All this points to the necessity of reeducating the public to the importance of a well-conditioned body. To be physically fit an individual must have a good capacity for performance and endurance, sound physique and smoothly functioning organs, and adequate muscular strength; strength, speed, agility, and endurance must be a part of each individual. Each day holds a responsibility to go forward toward maximum fitness whether the future holds war or peace, a soft life or a hard life. The individual can fit only into such a niche as demands the capacity he possesses, so that the greater his fitness and his ability to maintain it at his peak capacity, the more life's doors will open to him. Fitness to enjoy life to its fullest—physically, emotionally, and spiritually—is the fitness that each individual really wants.

Too many American people have neglected to engage in regular systematic exercise. Few men (except when there is a war at hand) make an effort to reach and maintain top physical condition. Only the 10 or 15% of boys and young men in the secondary schools and colleges who are out for varsity teams get in fairly good condition. The other 85 or 90%, as a rule, do not attain a high degree of physical fitness. The percentage of Americans who lack this high degree of physical fitness becomes much higher when we limit our study to men and women over 30 years of age. Although America is known as the land of sports, there is not a widespread intensive participation in sports on the part of the majority. A visit to any of our large bathing beaches during the summer will reveal thousands of individuals clad in bathing suits and lying on the sand, but few of them actually swimming. Probably many of them do not know how to swim, and, of those who do, a swim of 10 or 15 yd. at a time is the usual limit. Then, too, there are many sports spectacles in this country, but, except for the few players who are participating, there is not much exercise taking place. So it is obvious that too many people function below their normal capacity. It seems essential that, if we desire to get the most out of life, we must learn to increase the demands on the body and develop greater power, strength, and endurance for sustained effort. We must work for poise and skill in the use of our bodies.

Benefits of Exercise

There is no doubt that exercise benefits the body in many ways. Physical strength and general body conditioning are essential for growing boys and girls. Sufficient strength, particularly in the arms and shoulder girdle, the abdomen, and the pelvic girdle—a basic torso strength of all large muscle mass—is essential in order to have good control of the body. Participation in various sports, either for conditioning exercises or for body building, must be considered as one means of attaining such strength. Formal exercise can accomplish the same goal. It is a well-known fact that an individual is much more efficient in the performance of a skill if the muscles involved are in the best of condition. This implies specific concentration upon their development. The physical benefits of such exercises are improved posture, flexibility, agility, good balance, increased strength, and endurance. The functions of the various systems of the body are improved by exercise. For example, the general circulation of the body is accelerated, and the improvement results in food and oxygen being carried more efficiently to the body tissues.

In addition to physical development, exercise has a soothing effect upon the nervous system. During exercise the nervous system becomes more active than during sedentary mental work, but less fatigue results because the physical fatigue that comes from vigorous exercise serves as a mental tonic. Furthermore, a person who is physically fit does not have to apologize for being unable to engage in an activity, and he often finds himself able to do many things formerly considered beyond his capacity. Finally, when the desire for activity has been satisfied through the performance of wholesome physical activities, significant mental satisfactions follow. The person who is physically fit has an indescribable feeling of virility and power. He is much better prepared for meeting the problems of his day than if he were "soft" and out of condition.

Exercise also is an organic means of remedying the past neglect of the body, for, even if the body has not been given sufficient exercise, nature quickly helps to repair this past neglect. A program of exercise that involves the large muscles of the body and is not too severe at the start soon causes the body to respond. The organic systems begin to show new energy, the muscular system begins to become better toned, and

---

Director, Payne Whitney Gymnasium, Yale University.

the flesh becomes more firm. Gradually the body shows greater endurance and more capacity for work, and there is a rapid recovery from fatigue.

Planning an Exercise Program

The primitive man had little choice in the matter of exercise; if he wished to survive he had to engage in many forms of activity. Today it is different. One must plan to allow time for healthful exercise, and this exercise must be adapted to one's age and present physical condition. When one has done little or no systematic exercising, he must naturally go easy at first, for perhaps three or four weeks. Especially after an individual reaches 25 or 30 years of age, exercising must be gradual, because the muscles and arteries lose some of their elasticity and are unable to withstand the strain of sudden or prolonged vigorous activity. Regularity of exercise, however, is the important factor, along with this gradual increase in difficulty.

Adapting the type and amount of exercise to the individual must be stressed. The busy person who can give only a little time each day to physical exercise might do well to select an exercise for each part of the body: for posture; for strengthening the abdomen; for arms, shoulders, and legs; and for raising the chest and strengthening the muscles of the upper back. Such a routine might include exercises from a supine position, such as pelvic rolls, sit-ups, raising the knees, rotating the knees, or the exercise in which the toe touches the opposite extended arm. From a prone position, such exercises as hip raising (jackknifing the body up and down) or chin-up (lifting the head) would be helpful. Also, the individual might try the following exercises: sitting with legs straight, he might stretch by bending his trunk forward; sitting with his hands behind his head, twist his trunk; or squatting, imitate a jumping jack.

The general rule, "remember your age," must be adopted, because men and women under 30 may exercise with more speed and endurance than those over 30. After 30, one should work for endurance and not for speed. Just as "an apple a day keeps the doctor away," so a little regular and systematic exercise each day will help the individual to meet daily tasks with a better body and a more alert mind.

1553 Timothy Dwight College.

EFFECT OF WARMING-UP UPON PHYSICAL PERFORMANCE

Peter V. Karpovich, M.D.
and
Creighton J. Hale, Ph.D., Springfield, Mass.

• *Three methods of warming-up were compared as to their effects on the time required for seven athletes in a 440-yd. (402-m.) run. The means were obtained from 20 runs after five minutes of deep massage of each leg, 20 runs after five minutes of superficial massage (digital stroking) of each leg, and 20 runs after preliminary exercise. The differences found among these three methods of warming-up were statistically not significant. In a second experiment the performance of five runners in the 440-yd. run without warming-up exercise was compared with their performance after superficial massage; again the difference was insignificant. In a third experiment, an attempt was made to verify reports of other investigators that warming up by preliminary exercise improved performance; the test consisted of completing 35 pedal revolutions of a bicycle ergometer in the shortest possible time, the amount of work being 956 kg.-m. The warming-up exercise consisted of 60 pedal revolutions per minute for five minutes with a load of 5.5 lb. (2.5 kg.); it increased the mean muscle temperature by 1.3 C (2.3 F), but the effect upon performance again was not significant. Outstanding performances in the first experiment were made by men who had warmed up by deep massage, but an outstanding performance in the second experiment was made by a man who had not done any preliminary warming-up. In these experiments neither deep or superficial massage nor preliminary exercise improved the time of running; there was no evidence that massage had a beneficial psychological effect on the runner or that preliminary exercise improved sprint performance on the bicycle ergometer.*

It is almost axiomatic with coaches and athletes that a preliminary warming-up is indispensable for a good performance. The type and duration of warming-up varies, depending upon the country, the coach, the sport, and the individual preference of the athlete. Warming-up may be subdivided into two types, general and formal. In the general type, one may use exercises involving large groups of muscles, massages, hot showers, or other devices to raise the temperature of the body. In the formal type, warming-up consists of the movements that are used in the actual performance.

Two reasons are advanced for general warming-up. It is said that the strength and speed of muscular contraction increase with a rise in muscle temperature, and that the possibility of injury due to sudden forceful muscular contraction is lessened. The formal warming-up is credited with an improvement of coordination. While there seems to be general agreement regarding the importance of the formal type of warming-up, the effects of general warming-up may be questioned. True, no one will question the beneficial effect of warming-up when limbs may be almost numb from cold, but there is a suspicion that the practice of warming-up is frequently overdone.

To our knowledge no objective evidence has been presented that warming-up reduces the number of athletic injuries. As to the experimental evidence of an improvement in performance resulting from warming-up, there have been few studies reported. Asmussen and Bøje[1] studied the effect of preliminary work,

Read in part before the annual meeting of the American College of Sports Medicine, Chicago, March 24, 1956.

short-wave diathermy, hot shower, bath, and massage upon performance on the bicycle ergometer. All methods of warming-up, except massage, were reported to be beneficial in both sprint and endurance rides. Schmid,[2] on the other hand, reported that not only setting-up exercises, hot bath, diathermy, and shower with alternating hot and cold water but also massage improved performance of both men and women in swimming 50 m., running 100 m., and riding the bicycle ergometer. Simonson and co-workers [3] also found that preliminary exercise improved running time of the 100-m. run for both men and women.

Malarecki [4] reported that not only actual warming-up exercises but merely imaginary exercises increased the speed of running 60 m. Hipple,[5] on the other hand, found that preliminary running had no beneficial effect upon the speed of a 50-yd. run. Carlile [6] reported that an eight-minute hot shower caused a 1% improvement in swimming 40 yd. The scholarly report of Asmussen and Bøje was most convincing. However, their negative findings regarding the effect of massage prompted us to investigate the effect of this type of warming-up. This investigation lead to two additional ones. Thus this paper represents a report on three series of experiments.

First Experiment

On the evidence presented by the previous investigators it was assumed that, except for massage, the various methods of warming-up beneficially affected physical performance. Therefore, the first study was designed to compare the effect of deep massage with that of preliminary exercise upon time of running 440 yd. In order to detect any possible psychological effect of massage, we decided to use performance after a light superficial digital stroking as a control.

Procedure.—Seven track athletes of Springfield College were used as subjects. All had previously run the required distance of 440 yd., and all were members of the freshman or varsity track teams. Each subject warmed up and performed individually on an outdoor track. A total of 60 test runs was made, 20 after deep massage, 20 after preliminary exercises, and 20 after digital stroking.

Digital stroking consisted of slow, gentle, rhythmic, and centripetal stroking covering the entire leg for a five-minute period. When deep massage was used, a five-minute general massage of each leg was administered. The same investigator served as masseur in all cases. Preliminary exercises included jogging 440 yd., setting-up exercises, and short sprints of 20, 30, and 50 yd. This warming-up took approximately 10 minutes. In deciding on the duration of warming-up, we were influenced by the findings of Asmussen and Bøje, who reported that the first five-minute period had the greatest effect. To be safe, we doubled this period.

Three afternoons a week for a three-week period were used for testing. It was observed that trackmen appeared to run better toward the end of the week than at the beginning, so a rotation of methods of warming-up was used. For example, the first week the subject would receive digital stroking before his performance on the first test day, on the second day he would receive deep massage, and on the third test day he would use exercises. The methods of warming-up were then rotated, so that on the first test day of the second week the subject would receive deep massage; the second test day, exercises; and the third test day, digital stroking. The third week the methods were rotated one step more, with the subject receiving preliminary exercises the first test day, digital stroking the second test day, and deep massage the third test day. All methods of warming-up were used on each test day in order to minimize the effect of such uncontrollable variables as the condition of the track and the effect of the wind. Thus, some subjects were given digital stroking, some were given deep massage, and some were given exercises on the same test day.

Results.—It can be seen in the table that there was no statistically significant difference in the running times after deep massage, preliminary exercises, and digital stroking. Since the difference in times was not statistically significant, the psychological effect of massage was not discernible.

Second Experiment

Because the results obtained in the first experiment showed that performances were equally good after deep massage, preliminary exercises, and digital stroking, the second experiment was conducted to compare the running time after digital stroking with that of a "cold run," when no preliminary warming-up was used.

Effect of Various Methods of Warming-Up on the Time of Running a Distance of 440 Yd.

Method of Warming-Up	Mean, Sec.	Standard Error, Mean	Standard Deviation	t-Ratio
Deep massage	55.6	1.53	4.05	0.48*
Digital stroking control	56.6	1.41	3.74	
Preliminary exercise	56.0	1.38	3.65	0.28*

* The differences in performance are not statistically significant.

Procedure.—Five highly trained varsity and freshmen track athletes of Springfield College were used as subjects. Each subject was tested four times, twice without warming-up and twice after digital stroking. The activity selected for testing was the 440-yd. run on an indoor track. As in the first experiment, digital stroking was used in order to detect any possible psychological effect of massage.

Results.—The average running time when no preliminary warming-up was used was 59.2 seconds, while the average time attained after digital stroking was 59.5 seconds. The computation of the *t*-ratio indicates that the difference between the effects of these two methods is not significant. The results may also be interpreted to mean that, whatever the psychological effect of digital stroking could be, it did not affect the running times.

Third Experiment

From the results of the first and second experiments, it was concluded that neither massage nor preliminary exercise improved the time of running 440 yd. Our conclusion that massage had no beneficial effect substantiated the findings of Asmussen and Bøje. However, the finding of lack of improvement after preliminary exercise, which is contrary to the findings of the previous investigations, made it necessary to study once again the effect of preliminary exercise upon performance. Since the only activity engaged in by the subjects was walking to and from classes and from the last class to the test, the question arose as to whether this walking was sufficient to substantially raise muscle temperature.

Procedure.—Warming-up prior to the performance consisted of riding the bicycle ergometer at a speed of 60 pedal revolutions per minute for five minutes with a load of 5.5 lb. On days the subjects rode without warming-up, they reported to the laboratory and without any preliminary warming-up they were given their test rides. No subject had been engaged in any physical activity for at least two hours before the test rides except walking to and from classes. The test rides were the same as the sprint performances used by Asmussen and Bøje, which they assumed to be equivalent to the 100-m. run. Each ride consisted of completing 35 pedal revolutions in the shortest possible time, the amount of work done being 956 kg.-m.

The three Springfield College students who were used as subjects were all excellently trained for this experiment, since they had just completed riding the bicycle ergometer for another study that had continued for several months. Twenty-four test rides were made: 12 after preliminary warming-up and 12 without preliminary warming-up.

Results.—The average time for the sprint rides without preliminary warming-up was 14.2 seconds, and that with preliminary warming-up was 13.7 seconds. Computation of the t-ratio showed that the warming-up did not have a significant beneficial effect on sprint rides on the bicycle ergometer.

Comment

If the interpretation of the obtained data were made on the basis of mean time of performance, it would have appeared that deep massage and preliminary exercise have a beneficial effect upon performance. A statistical analysis of the difference in time, however, showed that it was not significant and fell within the limits of experimental error.

The muscle temperature of men in the third experiment was 36.4 to 37.0 C (97.5 to 98.6 F) in cold state and 37.6 to 38.4 C (99.7 to 101.1 F) after warming-up. Therefore, a similarity between performance time with and without preliminary exercise cannot be explained by assuming that subjects who were scheduled to have a cold run warmed up by walking to the laboratory.

The running times recorded during the tests indicated that all subjects exerted maximum effort. In the experiment on the outdoor track, two of the subjects ran their fastest time of the track season. Both these performances occurred after warming-up by deep massage. One of the subjects in the second experiment surpassed the Springfield College indoor track record for the 440-yd. run. He ran without any preliminary warming-up.

Summary and Conclusions

Three series of experiments were conducted to determine the effect of warming-up upon physical performance. In the first experiment, seven trackmen ran 440 yd. after deep massage, exercises, or digital stroking. Digital stroking was used as the control and to study possible psychological effects of massage. In the second experiment, five men ran 440 yd. without warming-up and after digital stroking. In the third experiment, sprint rides on the bicycle ergometer after preliminary exercises and without warming-up were compared.

The experiments showed that deep massage, digital stroking, and preliminary exercise did not improve the time of running a distance of 440 yd. They also indicated that there was no beneficial psychological effect from massage. Finally, preliminary exercise did not improve sprint performance on the bicycle ergometer.

Radioautography.—The term radioautography denotes a method of studying the distribution of radioisotopes which have become incorporated in an organism by observing the patterns created when the radiation from the isotope impinges upon a photographic film placed near the tissues. Radioautography is superior to the counting methods for some types of biomedical research with radioisotopes. For instance, accurate determinations of the sites of deposition of isotopes in organs and tissues (and in special cases in individual cells) can be made by means of radioautography. It is also possible to estimate the relative quantities of radioisotope in the various parts of a tissue. Occasionally, amounts of radioisotopes which will barely record on a counter will yield useful information by radioautography since the photographic film can integrate the radiation dose over a much longer time than is practical with Geiger-Mueller or scintillation counting. Furthermore, accurate counting radioisotopes in tissues requires the destruction of the tissue either by ashing, dissolving in acid or alkali, or homogenizing. This is not necessary with radioautography where the tissue, or at least the histological slide, remains intact and may be correlated with the pattern of the radioautogram. Several variations of the techniques of radioautography have evolved—such as: placing a photographic film (with its backing) in apposition with an histologic slide, floating the film (free of its backing) onto the tissue, mounting the tissue directly on a cut film instead of a slide, painting the melted film emulsion over the tissue on a slide, as well as others, and combinations of those stated. . . . In preparing the tissue slides for radioautography the chemical state of the isotope being used in the study determines the methods used for fixation and staining. Many of the reagents used in fixation, embedding, and staining may mobilize the isotope under investigation, removing it partially or entirely or causing it to diffuse more or less uniformly through the tissue. . . . In setting up new work it is well to monitor the various reagents through which the tissues are processed. If it appears that significant amounts of isotope remain in the reagents the method should be changed. All manipulations of the tissue should be such that the isotope is retained in its original positions.—D. Joftes and S. NUTRITION AND ATHLETIC PERFORMANCE

Theodore B. Van Itallie, M.D., Leonardo Sinisterra, M.D.
and
Fredrick J. Stare, M.D., Boston

• *The performance of an athlete can be impaired significantly by a faulty or inadequate diet, even before clinical signs of a deficiency are manifest. But the manipulation of an already adequate diet does not enhance performance. The composition of a meal preceding single-effort events like the high jump has little effect on performance, but performance in tests involving prolonged muscular work is enhanced if carbohydrate stores are replete at the beginning of the test. Obesity is a mechanical handicap in most, though not in all, forms of athletics. The average corporeal density of athletes is higher than that assumed for the general population; therefore the usual height-weight tables give the misleading impression that an athlete of given height is too heavy and presumably obese. Placing him on a reducing diet would be a mistake. Ordinarily he will spontaneously ingest food in amounts sufficient to maintain his weight. Performance is generally influenced by motivation, skill, and other neuromuscular and psychological factors. The training table provides the athlete with the foods on which he has learned he can rely; it also provides some of the sense of security generally obtainable by the practice of rituals. The best diet for him is a balanced one consisting of a variety of the foods he enjoys, in amounts that maintain his weight at an optimum level.*

Manipulation of the diet in order to enhance physical performance is a procedure that has its roots in the superstition and magic of the unrecorded past. At one time, men swallowed powdered lion's teeth to make them strong. Similar practices are still carried on in primitive cultures. For many centuries the popular belief existed that violent muscular exercise requires the eating of a large amount of meat, and in the 19th century Liebig gave scientific support to this tenet by proposing that during exercise the substance of the muscles is used up. He stated, "All experience proves that this conversion of living muscular substance into compounds destitute of vitality is accelerated or retarded according to the amount of force employed to produce motion." Subsequent experiments showed conclusively that heavy exercise is not associated with any significant increase in loss of nitrogenous material; however, the conviction that meat was the food par excellence of the athlete was so strong, and the prestige of Liebig so great, that a number of years passed before the doctrine of "meat for muscular work" was reluctantly discarded.

According to Drummond and Wilbraham, concern for the diet of athletes paralleled the growing interest sport that began to be apparent in England toward he end of the 18th century. Early in the 19th century, it was customary for the athlete to begin his training with a series of strong purges to clear away "all the noxious matter he may have had in his stomach and intestines." After this "purification," unseasoned red meat (preferably underdone), bread, and mild beer were prescribed. Drummond and Wilbraham have written:

> The Oxford crew in the 'sixties trained on a diet of underdone beef or mutton, bread, tea and beer, with a little jelly or water cress as a treat at the evening meal. Instructions were given that no vegetables were to be eaten. Cambridge, on the other hand, suffered no restrictions regarding potatoes, greens, or even fruit. From 1861 to 1869 there was an unbroken succession of Oxford victories. So much for vitamins in athletics!

It is convenient to consider the effect of diet on physical performance at two levels: psychological and physiological.

Psychological Considerations

Much still needs to be learned about the effect of the psychological state of the athlete upon his performance. Yet, it is widely agreed that motivation plays a major part in determining whether an athlete will win a contest. The food that is consumed during training and immediately before an athletic contest may have a psychological significance for the athlete that exceeds its physiological and metabolic importance. The significance of eating rare meat as a symbol of manly vigor and strength is obvious. In the course of his training program, the athlete frequently must work hard and forego many pleasures. Accordingly, his need for gratification is accentuated. Some of this need can be met by providing him with appetizing foods, such as special desserts and rare beef. This provision makes him feel that training has its incidental rewards and helps to prevent him from "going stale." Presumably, there is an element of atavism in the emphasis on eating meat at the training table.

The drinking of milk (although not always recommended at the training table) has in some cultures become associated with the idea of health and "clean living." Then, too, the training table may provide some of the sense of security and reassurance generally obtainable by the practice of rituals. Use of various rituals by athletes in preparing themselves emotionally for contests is well known. Thus, food has a significance far beyond the nutrients it provides. Also, the atmosphere in which food is served is frequently more important than the quality of the food served. The morale value of turkey at Thanksgiving has been recognized by the military services, and on this holiday American soldiers stationed in far-off lands are served turkey, regardless of the cost involved.

From the Department of Nutrition, Harvard School of Public Health. Dr. Sinisterra is a Rockefeller Foundation Fellow in Nutrition.

A number of studies have purported to show that between-meal feedings during working hours improve the efficiency of performance of industrial workers. However, when such studies have been repeated with use of suitable controls, it has usually been possible to demonstrate that the beneficial effects were psychological rather than physiological in origin. When ingestion of sugar before an athletic performance seems to have a salutory effect, it is difficult to decide whether this response occurs for psychological or physiological reasons.

In view of the importance of psychological factors in modifying physical performance, it would be unwise and unjustified to deprecate the psychological value of food, and of the ritual of the training table for the well-being of the athlete. However, it seems important to study these psychological aspects of food and the training table carefully in order that their contribution may be better assessed and clearly distinguished from possible physiological and metabolic factors.

Physiological and Metabolic Considerations

Digestion and Athletic Performance.—Considerable attention has been paid to the pregame or preevent meal. As Bensley has pointed out, the chief consideration to be borne in mind in planning this meal is the emotional stress that the athlete may experience on the day of the contest. Loss of appetite, abdominal discomfort, and even nausea, vomiting, or diarrhea may occur. If the meal is taken too close to the game or event, the anxiety of the athlete may interfere with appetite and digestion. Moreover, the distended stomach may impair performance. Therefore, in most cases, the preevent meal should be consumed not less than three hours before the contest. Individual food preferences should be respected. The athlete knows from experience which foods can be eaten without causing him discomfort. As a general rule, only foods known to be highly digestible should be consumed as part of the preevent meal.

Sources of Energy During Athletic Activity.—It is clear that variations in the normal diet cannot significantly influence the coordination and controlled expenditure of energy required in an athletic performance. These are matters of endowment and training. Conceivably, changes in diet may affect the amount of energy and the rate at which this can be made available. Obviously, an enormous variation exists in the expenditure of energy by athletes, and many classifications have been used to divide athletic performances in terms of energy expenditure. One such classification distinguishes four groups: (1) single-effort field events, such as the high jump, the broad jump, putting the shot, and pole vaulting; (2) sprints and hurdle races; (3) middle-distance runs, such as the mile run; and (4) prolonged efforts taking more than one hour, as exemplified by the marathon.

From what is known about intermediary metabolism, it would appear that the sources of energy for these classes of endeavor may be somewhat different. For example, in the single-effort events and sprints requiring bursts of effort, the body can make use of stored energy readily available from the energy-rich organic phosphates, adenosine triphosphate, and creatine phosphate. However, in order for the high-energy phosphate bonds of these compounds to be regenerated, fuel must be metabolized. To a limited extent, energy-rich phosphate bonds can be regenerated by the breakdown of glycogen to lactic acid, a process that does not require oxygen. However, the major supply of energy expended by the body is derived from the complete oxidation of small fragments derived from carbohydrate and fat. Indeed, per molecule of glucose, oxidative phosphorylation is much more effective than the phosphorylation connected with lactic acid formation.

In the 100-yd. dash, the oxygen requirement is over 6 liters. Since the human respiratory and circulatory equipment can provide only approximately 4 liters of oxygen per minute, it is clear that muscles are able to perform work and replenish energy stores for a limited time in the absence of oxygen. This is accomplished primarily by the breakdown of glycogen to lactic acid. However, this process is self-limited, since under such circumstances high-energy phosphate bonds are not regenerated as rapidly as they are broken down. Moreover, an accumulation of lactic acid in the blood occurs as a consequence of massive anaerobic glycolysis, and before long the products of the reaction, glycogen → lactic acid, accumulate to a point where the reaction itself can no longer proceed. Lactacidemia also may unfavorably affect blood acid-base balance and, consequently, the metabolic and physiological functions that depend on the maintenance of pH level within a certain optimal range. The oxygen needed to make up the energy deficit incurred during muscular exertion in the absence of adequate oxygen intake has been termed the oxygen debt. Not all of the oxygen debt is associated with lactic acid production: the balance ("alactacid" oxygen debt) may be used to restore creatine phosphate and adenosine triphosphate levels, and possibly to metabolize accumulated ketone bodies.

During the recovery phase, oxygen in excess of current needs is taken in to make up this deficit, which may be as high as 16 liters. In large part, the extra oxygen is used to oxidize the lactic acid accumulated during the deficit period. Such an oxygen debt can be incurred rapidly or more slowly. In practical terms, if an athlete exercises to a degree so that he needs 8 liters of oxygen per minute, he can maintain such a pace for only approximately four minutes, since in that time he will have reached the oxygen debt "ceiling" of about 16 liters. Since the oxygen requirement increases rapidly with an increase in running speed, the ability of the sprinter to achieve a pace almost 50% faster than that of the mile runner becomes readily explicable in physiological terms.

It must be emphasized that the body is not able to maintain an intake of 4 liters of oxygen per minute for very long. If exercise has to be maintained for a matter of hours, oxygen consumption approaches one liter per minute. Thus, as the energy expenditure of the athlete becomes more prolonged, its intensity must diminish. As its intensity lessens, the relative importance of the oxygen debt mechanism also diminishes. For moderate distances, the runner may depend in part on his "recovery" period; for long distances, he must run in a "steady state" (the condition in which the intake of oxygen meets the metabolic needs of muscle).

It would seem that, in the first three classes of athletic events listed above, the fuel supply is an item of minor concern, since the amounts of energy used are relatively small. In the fourth class, where endurance may be a deciding factor, the fuel supply becomes relatively more important. In any event, since diet does more than merely provide fuel for muscular activity, a more detailed analysis of the ways in which diet can influence performance is appropriate. Before such an analysis can be undertaken, however, the methods and criteria used in the assessment of physical performance should be briefly considered.

Influence of Diet on Physical Performance.—It has already been mentioned that motivation, skill, and coordination play important roles in determining the outcome of athletic contests. Thus, it is inherently difficult to study the problem of diet in relation to performance under satisfactorily controlled conditions. As Marrack has stated, "Excellence in athletics does not depend so much on the energy output by muscles and the rate at which this output can be maintained as on the skill with which this energy is used." Use of studies with animals in assessing the effect of diet on performance is not a particularly helpful procedure because of the difficulty in interpreting in human terms quantitative changes that may be measured in experimental animals. Keys has properly stressed the importance of using rigid standardization and has criticized many earlier studies because they were not sufficiently prolonged to eliminate the period of adaptation to a new dietary pattern suddenly imposed on the experimental subject.

Generally, the criteria used involve measurement of performance of an actual physical task, such as swimming 100 yd. or running a mile. The responses of such physiological factors as pulse rate, body temperature, and time of reaction to muscular activity also serve as indication of the ability to perform under standard conditions. Biochemical changes in the blood, particularly variations in values of blood glucose, lactic acid, and ketone bodies, have been measured during and after a standard task and used as indexes of performance.

The term "efficiency" applied to muscular activity is a technical expression that refers to the energy cost of mechanical work. Ordinarily, efficiency is calculated in one of two ways: as gross efficiency (total energy output in relation to mechanical work done) or as net efficiency (the increment of energy output over some predetermined base-line energy output, such as the resting or the basal metabolic rate, in relation to mechanical work performed). Gemmill has discussed the merits and disadvantages of such calculations in a comprehensive review. Of numerous methods for measuring the mechanical energy developed by man during exercise, the most commonly used is the bicycle ergograph. Considered as a machine, man operates at a maximal efficiency of about 25% (calculated for climbing stairs); this is somewhat better than the ordinary gasoline engine but not as good as the diesel engine.

In his review of the problem of physical performance in relation to diet, Keys has listed three ways in which special dietaries might influence muscular performance. These involve (1) renewing the supply of energy-yielding nutrients, (2) facilitating the energy-yielding reactions, and (3) counteracting physical-chemical changes in the body identified with fatigue. A fourth way in which diet can favorably influence physical performance is by reducing any appreciable excess in fat content of the body. Such a decrease in adiposity will result in a proportional decrease in the energy cost of moving the body or its parts.

The first of these categories has to do with the fuels of muscular exercise—carbohydrate, fat, and, to a lesser extent, protein. Because vitamins are essential constituents of enzyme systems, which, in turn, are an important part of the machinery of energy metabolism, these nutrients properly fall into the second category, which is concerned with the problem of facilitating the energy-yielding reactions. Since fatigue is believed to be a manifestation of altered physiology induced by excessive muscular work, the influence of muscular work on homeostasis can be considered in the third category. Lastly, since excess fat results from a positive energy balance maintained for a prolonged period, the problem of reducing the athlete's weight must be thought of in terms of the caloric provision at the training table measured against the day-by-day energy expenditure calculated for that particular person. Moreover, in athletes, obesity (or its absence) is frequently not diagnosed by the simple measurements of body weight and stature. There is good evidence that the caloric status of the athlete is best demonstrated by a consideration of his bodily composition. (Although clinical deficiency states obviously can be associated with impaired performance, such disorders have been excluded from consideration in this paper. The present discussion is concerned primarily with the problem of determining whether there is such a thing as an optimal diet for a given category of athletic performance.)

Carbohydrate: Most observers have noted that, when carbohydrate is readily available to tissues, it is used preferentially for muscular work. However, as reserves of carbohydrate diminish, increasingly more fat is metabolized. Accordingly, either carbohydrate or fat, or any combination of the two substrates, can provide fuel for muscular exercise. Krogh and Lindhard reported that, when subjects are on a high-carbohydrate diet, they show a higher net muscular efficiency than when they are on a high-fat–low-carbohydrate diet. Calculations based on respiratory calorimetry indicated that up to 9% greater expenditure of energy per unit of work occurs when fat is being burned (the respiratory quotient equals 0.7). The findings of Krogh and Lindhard were continued and confirmed in their laboratory by Bierring. However, as Gemmill has pointed out, these authors used a projected line to obtain the two extremes for their calculations. As actually determined, the highest respiratory quotient obtained was 0.93, when the work expenditure was 4.6 calories; the lowest respiratory quotient was 0.75, when the caloric output was 4.82. Accordingly, the actual difference between these two measured points is 4.5%. March and Murlin were unable to distinguish any relation between efficiency and relative quantity of fat and carbohydrate in the diet when light work was performed but noted a decrease in efficiency on a diet high in fat after such a diet was continued for three or four days.

Haggard and Greenberg performed studies with the bicycle ergograph that led them to believe that a high carbohydrate intake increased muscular efficiency markedly and that an increase in the interval between meals was associated with a reduced efficiency. Other investigators have been unable to discover a beneficial effect of carbohydrate on performance. After reviewing the literature up to 1942 on the subject of the effect on efficiency of diets high in carbohydrate or fat, Gemmill concluded that muscular efficiency is practically the same on all diets. He states that there is a slight increase in efficiency after a high-carbohydrate diet; which probably does not exceed 5%.

In prolonged physical activity, a definite correlation can be observed between symptoms of fatigue and a decrease in blood sugar level. When glucose is administered under these circumstances, the symptoms disappear and the power to work is increased. Christensen and associates believe that the beneficial effect of administered glucose is a neurophysiological phenomenon and not due to a direct metabolic effect on muscle. Apparently the respiratory quotient can continue to fall (indicating increasing oxidation of fat) even while the level of blood glucose is rising and the symptoms of fatigue are being alleviated. In subjects studied for relatively short periods, Simonson and co-workers were unable to correlate visual fatigue with changes in blood sugar level. Apparently, fatigue is not necessarily accompanied by hypoglycemia, although hypoglycemia is frequently accompanied by fatigue.

Considerable literature has appeared concerning the effect of breakfast and its composition upon performance of work and emotional status. Tuttle and associates found that omission of breakfast affected adversely performance on the bicycle ergograph. Thorn, Quimby, and Clinton and others have observed that a breakfast high in protein has value in maintaining the blood glucose level and also a feeling of well-being. Yet, many of the effects of omission of a meal may result primarily from the sudden interruption of an established eating pattern. Studies on individuals who habitually omit breakfast might be more rewarding. Moreover, it would be inappropriate to apply results obtained in studies on industrial or clerical workers to athletic performances. Before an athletic event, the athlete may be in a psychological and physiological state not at all comparable to what might be anticipated under more casual circumstances.

Concerning dietary sugar and performance, the remarks of Abrahams seem pertinent.

> What of sugar, approbated as a readily available source of energy to be taken before a contest? It is conceivable that in a very protracted effort the reservoirs might be exhausted and hypoglycemia occur. But that a special sort of explosive material can be advantageously applied for a maximum effort I do not believe. It is perfectly true that I have given sugar with results that encourage the men to accord no little credit to its service. But the highly strung athlete is so suggestible that he will be powerfully influenced by anybody in whom he has confidence, in which case it is immaterial what he is given. I have been convinced of this psychological element with substances simpler than sugar and sometimes quite inert.

Haldi and co-workers have studied the effect of carbohydrate intake on physical performance, using the time taken to complete a 100-yd. swim as the index. When a high-carbohydrate meal was taken three hours before the swim, performance was not better than that after an isocaloric meal low in carbohydrate. Blood sugar concentrations were higher after a swim of this distance in all cases but were not affected by the composition of the preswim meal. Haldi and associates concluded that, in brief periods of very strenuous exercise, muscular efficiency is dependent upon the energy reserves and the training of the subject. The composition and size of the preexercise meal do not appear to play a significant role.

Although the preponderance of available evidence indicates that the composition of the preexercise meal does not affect efficiency during athletic events of brief duration, there appears to be little doubt that the capacity to endure prolonged muscular work is enhanced if carbohydrate stores are replete prior to the exercise period. Whether this favorable effect is due entirely to the maintenance of higher blood glucose levels or whether it can be explained in part by the slightly greater efficiency of muscular work when carbohydrate is the predominant fuel is not entirely clear. Christensen and others believe that, in the last few days before an athletic contest, heavy work should be avoided to allow for maximal filling of carbohydrate stores. However, more experimental work is needed before it can be stated with assurance that this belief is well founded.

Fat: There is no doubt that fat provides fuel for muscular work. In sustained exercise, when carbohydrate reserves diminish, the respiratory quotient falls, indicating that an increasing proportion of fat is being oxidized. However, fat seems to play a passive role in energy metabolism, in the sense that, when carbohydrate is available as a fuel for exercise, the respiratory quotient usually rises and the contribution of fat to energy metabolism diminishes in proportion. When exercise ceases, the respiratory quotient again falls to low levels, indicating that the metabolic mixture in the blood is largely composed of fat. In the diet of athletes (as in general), fat, at the metabolic level, acts as an indifferent source of energy. Beyond this, it makes no special contribution to muscular performance.

Protein: Since Zuntz and others have shown that protein is not metabolized in significant amounts during muscular exercise in the well-nourished person, it need be considered only briefly, as having an energy-releasing reaction. The importance of meat as a constituent of the diet of athletes has been much debated, but it would appear that an excess of meat at the training table probably has more psychological than physiological value. The requirement for protein is not significantly increased when exercise is performed, unless at the same time an increase in muscle mass is taking place.

Yamaji carefully studied protein metabolism in several students who were being subjected to a rigorous training program for approximately one month. He observed that as the training progressed the nitrogen balance became positive. When the regular diet, containing 1 to 1.5 gm. per kilogram of body weight of protein per day, was fed, retention of nitrogen was relatively small; however, when the protein content of the diet was increased to 2 gm. or more per kilogram of body weight per day, an increasing amount of nitrogen was retained. This investigator also followed changes in the reserve protein during training for heavy muscular work and found that early in training the hemoglobin and albumin contents of the blood decrease. The degree of decrease in these blood proteins and the rate of their recovery are apparently influenced by the amount of protein in the diet. The higher the dietary protein intake, the smaller is the decrease in hemoglobin and serum albumin levels at the beginning and the sooner the return to normal.

As a result of these findings, Yamaji has concluded that during training protein accumulates in muscles at the expense of blood proteins. He has recommended that, during training programs involving heavy muscular work, an excess of protein be consumed. Such a diet would help to prevent anemia and permit the muscle mass to increase in size more rapidly. If Yamaji's results can be confirmed, it would mean that hemoglobin synthesis does not necessarily take precedence over other protein requirements, as some studies have implied. In any event, it seems clear that determinations of nitrogen balance during periods of rigorous training indicate only whether a net catabolism or anabolism of protein is taking place.

Additional studies, including determination of body constituents, are needed to provide information about important internal changes in protein metabolism that may be taking place. The studies of Yamaji and his colleagues deserve to be carefully followed up in the United States, particularly with respect to changes in reserve or labile protein that may occur during conditioning periods in athletes who have been out of training for some time. If the athlete is a growing boy, he will need extra protein to meet this particular anabolic requirement, whether he is in training or not.

Vitamins: It is now widely recognized that many vitamins of the B group are important constituents of coenzymes that participate in the energy-releasing reactions for which carbohydrate and fat provide the major substrates. The specific vitamins known to be involved are thiamine (cocarboxylase), riboflavin (flavoprotein coenzymes), nicotinamide (diphosphopyridine nucleotide, or coenzyme 1, and triphosphopyridine nucleotide, or coenzyme 2), pantothenic acid (coenzyme A), and probably pyridoxine (codecarboxylase) and biotin (carbon dioxide—fixation coenzyme). The rationale for believing that vitamin supplements might significantly affect physical performance involves the assumption that subclinical vitamin deficiencies are not uncommon in apparently well-nourished persons or, failing this, that it is possible to supercharge the energy-producing reactions by providing an excess of vitamins.

Keys and his associates were unable to discover any benefit to performance of work or capacity from large daily supplements of the B vitamins given to soldiers maintained on ordinary U. S. Army garrison rations. In his review, Keys states that he has been unable to find convincing evidence that supplements of the B complex or vitamins C or E, separately or in combination, would enhance the physical performance of apparently well-nourished persons. Bourne has recommended a high vitamin intake for athletes on the ground that the requirement for certain vitamins may be enormously increased in strenuous exercise. Actually, there is very little evidence to suggest that the requirement for vitamins is appreciably increased during prolonged muscular work. At best, the requirement for certain vitamins may increase in direct arithmetic proportion to the increase in expenditure of energy. In spite of occasional reports of apparently beneficial effects of vitamin supplementation upon athletic performance, it remains to be demonstrated convincingly that supplementation of the diet of the athlete in training with vitamins of any sort has a beneficial effect on endurance, muscular efficiency, or coordination.

Electrolytes and Blood Acid-Base Balance: After brief periods of strenuous exercise, there occurs a marked increase in production of lactic acid by the working muscles. At the same time a moderate increase in production of pyruvic acid takes place. These values are greatest 5 to 15 minutes after such exercise but remain comparatively high during the balance of the recovery period. According to Christensen and coworkers, the rise in lactic acid brought about by work of definite severity becomes less for the subject in better training. However, there is no evidence that the trained subject can dispose of excess lactate more rapidly than the untrained person.

The mechanism of lactacidemia has already been discussed. However, since severe exercise is associated with an accumulation of large quantities of organic acids, alkalinizing procedures have been suggested as having possible value in relieving the fatigue of the athlete. Johnson and associates studied the effects of blood alkalinizers on the efficiency of runners and found that their running times were not shortened by such measures. Keys has concluded tentatively that such changes in the alkaline reserve that may be effected by dietary manipulation will have little influence on the ability of the normal person to perform muscular work.

When carbohydrate stores are depleted during prolonged strenuous exercise, a rise in blood level of ketones may be anticipated. According to Grollman and Phillips, the degree of ketonemia occurring under controlled dietary conditions during performance of a standard task involving muscular exertion varies directly with the degree of training of the individual performing the task. They postulate that the greater rise in levels of blood ketones in the trained individual may represent a more efficient pathway for fat metabolism under these circumstances. Grollman and Phillips also have suggested that accumulated ketone bodies may represent that portion of the oxygen debt not accounted for by lactacidemia. Incidentally, there appears to be no evidence that the mild to moderate ketonemia of exercise during a time of carbohydrate depletion is in any way deleterious.

Frequently, athletic contests are carried on during hot weather and are associated with excessive losses of sodium chloride and water from the skin. Obviously, under these circumstances, replacement of salt and water is needed. Keys and associates have found that work capacity in heat is markedly reduced when salt is severely restricted, even when this does not involve heat cramps or heat hyperpyrexia. At least 2 to 3 gm. of sodium chloride must be replaced per liter of sweat lost. Salt tablets may be upsetting to the digestive tract, and many physicians have found a weak solution of sodium chloride to be better tolerated by the individual deficient in salt.

Calories and Body Weight: Ordinarily, the athlete will spontaneously ingest food in amounts adequate to maintain his weight. It is unusual for obesity to develop during a period of rigorous physical conditioning; however, if the training-table food is appetizing and also calorically concentrated and the training itself moderate, it is quite possible for the athlete to accumulate fat during the training period. If the athlete has allowed himself to gain fat intercurrently, he will tend to lose it during the training period. It is axiomatic that the athlete who decreases his total weight by losing excess fat will be a more efficient machine. Accordingly, for most forms of athletics, obesity, even to a mild degree, constitutes a mechanical handicap.

The development in Germany of a light, portable respirometer has made possible the convenient collection of fairly accurate information about the caloric cost of different kinds of athletic activity. In assessing the nutritional needs of athletes, it is clearly important to obtain reliable information about the calories expended by the athlete in the performance of his particular event or events. Passmore and Durnin have carefully reviewed much of the recent information on the subject of expenditure of energy of man. They have recorded figures for the energy costs of different sports expressed as calories per minute. For example, they note that skiing at moderate speed on level, hard snow involves a significantly greater energy cost than swimming the crawl at a rate of 55 yd. per minute. On the basis of quantitative information of this sort, it should be possible to obtain a better understanding of the caloric needs associated with a variety of sports.

As a result of application of dilution and densitometric methods, considerable information has been gathered concerning the body composition of athletes. Welham and Behnke studied 25 athletes and found that, on the basis of standard height-weight tables of the type used by the insurance companies and the military services, 17 fell into the overweight category. When these investigators performed determinations of specific gravity on the 17 subjects who, by conventional standards, would have been classified as obese, they discovered that 11 of the group possessed high corporeal specific gravity. This indicated that these particular "overweight" subjects actually had a relatively low content of body fat and a proportionately increased lean body mass. On the basis of these findings, the authors have proposed that overweight should be defined in terms of the specific gravity of the body mass, with a tentative dividing line at the value 1.060 (specific gravity) between the obese and nonobese categories.

If the conventional criterion of desirable weight, based on relationship between height and weight (modified by age), is used uncritically as a guide, it is conceivable that a number of lean athletes might be placed on reducing diets in the mistaken belief that they were obese. Such a procedure could only impair the athletes' ability to perform. Thus, in the assessment of the caloric status of athletes, it would seem particularly important to use criteria supplementary to the simple determination of body weight, such as the difference between circumferential measurement of chest and abdomen and the measurement of thickness of skin fold with appropriate calipers.

Summary

Ability to perform well in an athletic event depends primarily upon the skilled and coordinated use of a well-endowed and properly conditioned body; however, psychological factors such as motivation may be important in determining whether the athlete will win or lose a contest. Awareness on the part of the athlete of having regularly consumed an appetizing diet of wholesome foods at the training table is one of a number of factors that can have a favorable effect on his morale. A preevent supplement or meal taken in the belief that it will provide extra energy and thereby enhance performance also may have a beneficial psychological effect. Therefore, by affecting the psychology of the athlete, the training diet and the preevent meal can affect his performance. Since the athlete frequently experiences considerable nervous tension (with its digestive consequences) on the day of a contest, the preevent meal should consist of tried and true foods of a highly digestible nature taken some three or four hours prior to the event.

There is no evidence that the diet immediately prior to a short-term athletic event can be manipulated in such a way as to improve performance. In longer events requiring sustained muscular work, there is considerable drain upon the carbohydrate stores and a falling blood glucose level may be associated with marked fatigue. Accordingly, the degree to which carbohydrate stores are filled may affect endurance. A small increase in muscular efficiency is believed by some investigators to occur when carbohydrate rather than fat is the predominant fuel for muscular work. Whether such an increased efficiency can significantly influence athletic performance remains to be determined. In any event, it seems desirable to prepare athletes participating in contests requiring endurance with diets that will ensure maximal filling of carbohydrate stores prior to the event.

The trained athlete requires no extra protein; however, there is evidence that during rigorous training the diet should contain liberal quantities of protein in order to permit the muscle mass to increase rapidly and without cost to labile protein sources elsewhere in the body. Supplementary vitamins probably are not needed in the nutritional program of the athlete who is consuming a nutritious diet. A slight sodium deficiency can impair athletic performance before any clinical signs of sodium lack are discernible. There-

fore, during hot weather, adequate amounts of salt and water should be given to replace losses of these substances through the skin. Excess body fat can be an important mechanical handicap for the athlete; yet, caution must be exercised in diagnosing obesity in the athlete who is merely overweight in terms of the standard height-weight tables. Many "overweight" athletes are not actually obese and, for this reason, more informative measurements than those of weight and stature should be made when the athlete's caloric status is being assessed.

Although there is considerable doubt whether manipulation of an adequate diet can enhance performance, there is no doubt whatever that performance can be significantly impaired when a less than adequate diet is consumed. The best diet for the athlete is one he enjoys and one that, at the same time, provides a variety of nutritious foods in amounts adequate to maintain his weight at an optimal level.

PREVENTION OF INJURY IN ATHLETICS

Augustus Thorndike, M.D.,[*] Cambridge, Mass.

• During the 1955 football season, nine deaths were recorded throughout the course of play. This alone shows the need for an active program concerning the prevention of athletic injuries. As a prerequisite to such a program, accurate statistics must be obtained to show types of injuries and rate per exposure for all sports.

A preventive program must include a thorough preseason physical examination, with special emphasis on the history of prior injuries that the examinee might try to hide. There should then follow a period of physical conditioning under close medical observation, no matter what the sport or competition. The physician's responsibility, after all means of prevention have been utilized, lies notably in the immediate diagnosis, treatment, and prognosis of injuries sustained and in averting further aggravation of minor trauma. This is not the duty of the coach or trainer.

Closer medical supervision of athletics, perhaps with a program similar to that practiced by industry and the insurance companies for the protection of the worker, may be the means of reduction of athletic injuries.

Prevention of injury in industry has recently been brought to the attention of our reading public by James P. Mitchell, Secretary of Labor.[1] Information concerning the year 1955 reveals that on-the-job injuries and deaths involved 1,935,000 workers, with an economic loss calculated at 3.5 billion dollars. In spite of these appalling figures, we are informed that the disability injury rate per million hours worked has declined, from 20 in 1943 to 11.9 in 1954. In contrast with this organized effort of industry and of insurance companies to make all workers conscious of injury by specific training in accident prevention, one can observe little organized endeavor on the part of coaches, trainers, and others in the field of sports to institute training programs along the same lines. Sporadic changes in rules and regulations such as those pertaining to equipment and padding have partially benefited the safety of the game, but enforcement has been lax. Even the sports-loving spectator is stimulated to action when a good brawl is taking place on the ice or on the playing field. Of course, such brawls should not exist, according to the rules and regulations. "Baiting" the umpire by coach and/or player is often tolerated in our popular game of baseball.

Statistics on Injuries

Until such time as accurate statistical material concerning all sports and the number of regular participants is available, it will not be possible to ascertain the true incidence of injury per exposure in any one sport. Since 1931 the American Football Coaches Association[2] has made statistical reports on the fatalities of football. However, in this popular sport many disabilities occur that do not result in death but require treatment and absence from practice or games. A great need exists for an accurate tabulation on a national scale of all injuries resulting in disability for more than one day incurred in each sport. The problem of obtaining the necessary data for compilation is one of organization. Except for those of isolated educational institutions, such reports are now unobtainable. The American College Health Association, in cooperation with the National Safety Council, has attempted such a study but could obtain cooperation from only 11 colleges the first year and 9 the second year.[3] Reports in medical literature on the subject of athletic injuries are varied and usually concern particular types of injury. The information sought requires reports covering all professional sports and collegiate and high school athletics with formal, extramural competition. Basketball, baseball, football, soccer, lacrosse, boxing, and wrestling should be included in these reports. Such a large base for statistical compilation would furnish data of great value to those interested in the reduction of the incidence of injury in sports competition. I believe that the current incidence of injury is too high and should and can be reduced.

Need for Cooperative Effort

Our larger universities are interested in reducing the incidence of injuries in intercollegiate sports, as are the larger professional leagues in baseball, basketball, football, and ice hockey. However, due to a feeling of independence on the part of those in professional and amateur competition, too few have undertaken cooperative endeavor really aimed to benefit all competitors. Such an attitude has probably arisen as a result of the American definition of the amateur athlete. There has been much eyebrow-lifting over the international competition in the Winter Olympics in 1956, when those nations behind the Iron Curtain carried away most of the championships. Relying upon a fixed definition of qualifications for amateur competition, the Western sports world must examine its own code of amateurism. When does an athlete retain his true amateur status today? Whether amateur or professional, however, everyone interested in sports is interested in a program to reduce the incidence of injury and of fatality in sports. One is little cognizant of the facts. Is it realized that in the 1955 football season there were recorded nine deaths during play in American football and one death in the relatively harmless "touch" football?[2] In 1951 Gonzales[4] reported on deaths from sports; these data were derived from the files of the medical examiner's office in New York City covering 32 years, as follows: baseball, 43; football, 22; boxing, 21; and basketball, 7. Whatever program is adopted to reduce the incidence of injuries in sports will require deep thought and cooperation from all sides of the field: the professional, the amateur, the schools, and those responsible for sports in public and private playgrounds. The Metropolitan Life Insurance Company[5] has reported an astounding number of fatalities from sports injuries among its industrial policyholders, even in casual sports competition for fun (three fatalities in golf in two years). The medical interest in any program to prevent injury transcends any boundary, national or international, amateur or professional, sand-lot or organized.

[*] Chief Surgeon, departments of hygiene and athletics, Harvard University, and Lecturer on Surgery, Harvard Medical School.

Program for Prevention

Any suggested program on prevention of sports injuries begins with the compulsory preseason physical examination of all competitors. The physical examinations and medical history should emphasize prior injury and its sequelae, if any; vision; teeth and dentures; the heart and cardiovascular system; the respiratory system; the excretory system; and the musculoskeletal system. The examiner should look for the presence of large postoperative scars or any congenital or acquired abnormalities. A history of prior sprain of a ligament, strain of a muscle or tendon, or fracture is of great importance. Protective strapping has been demonstrated as useful in reducing the incidence of recurrent sprains and strains.[6] Many eager competitors like to hide the earlier injury, and the examing physician must be alert to note anything of this nature at the earliest possible moment. Cerebral concussion is occurring more frequently in the medical histories of the entering freshman athletes. It is often the result of an automobile accident rather than an accident on the playing field. A history of multiple concussions in a would-be college athlete interested in body-contact sports, when there has been loss of consciousness on three occasions, in our code automatically prevents him from entering competition and necessitates a detailed examination and consultation with the neurosurgical consultant. When the above-described physical examination uncovers only a marked abnormality of vision, the services of a consultant in ophthalmology are required. When there is correctible defective vision, contact lenses are ideal for those who can tolerate the prosthesis during exercise. In my experience, only a small minority of athletes can be comfortably fitted. When the physical examination is completed by the physician, the findings are reviewed by a higher authority on the medical staff and a complete list of approved candidates forwarded to the team surgeon, the team manager, and the team coach. No unapproved candidate can obtain a uniform.

After his acceptance as physically fit for a sport, the candidate reports to the squad and comes under the surveillance of the coach and training personnel. The fundamental training period is vital to the development of talent and technical and physical skills in all team sports. Actually more than the development of skill and talent is achieved through practice and drill. A physical conditioning is derived. No matter what sport may be considered or what game is played, certain fundamentals are required—in the basic knowledge of the sport, in the more advanced plays, in defensive maneuvers, or in offensive chance plays by which a temporary advantage is seized to gain or to score. In addition to the technical knowledge of the game and its rules, the physical strength to outlast opponents has more than once proved the winning factor in many a close contest. The coach and the trainer sense the quality of physical fitness and team cohesion as any season of sport proceeds.

One of the most difficult factors to deal with in a squad is the problem of overtraining. This is largely a problem of individual reaction, and one key man in the team can slow or upset the entire squad. Overtraining is a contagious affair that seems to travel unnoticed by squad members at the time, but a keen coach with an eye to individual members of his squad can spot and call it. It is better described, perhaps, as an unrecognized attempt to perfect some technical maneuver of a game to too ultimate a goal. Try as one may, the goal becomes succeedingly more impossible. However, the solution to this problem lies in more natural attempts, without trying too hard. Overtraining is largely mental weariness. Regardless of what sport may be concerned, one sees this. It is a bugbear of the coaching staff that the more experienced recognize early. The great problem of the coaching staff of any team, whether professional or amateur, is to develop the squad through graduated physical exercise and gradual technical training in offensive and defensive play, so that at the climax of the season, whether the goal be a world championship or a league championship, the squad has progressed to meet the challenge all the way through the competitive schedule. In the various professional, intercollegiate conference, and other leagues, the nervous tension felt during the sports seasons has reached a high level that 50 years ago would have been inconceivable.

The coach and training staffs do contribute to the program for prevention of injuries by teaching applicable techniques, particularly those related to defensive play in competitive sports. A very important detail pertains to the perfection of timing of team play in body-contact sports, in both offensive and defensive maneuvers. Lack of perfection in timing can produce uncalled-for injury; lack of proper execution of a play by one member of the team may result in unintended exposure of a teammate to uncalculated risk; and, unless alertness by team members to this potential risk is emphasized during squad drill or practice, a major source of the incidence of injury has been overlooked. All good coaches appreciate the necessity of squad drills in timing in complicated offensive and defensive play in all body-contact sports.

Another factor must be considered in prevention: the medical staff's responsibility for early recognition of injury to a member of the squad. Much has been written on the importance of early recognition of injury, the prompt removal of the player from the game, and the application of therapeutic measures, so that a minor sprain or strain may not become a major disability. Since the coach's main interest is in the technical perfection of team and position play, he should not be required to spot a limping or arm-weary player. The problems pertaining to minor injury should be the responsibility of the medical observer. Those of us trained in the process of observation for such details can perfect our visual sense so as to spot the milder type of injury before the player himself exhibits the aggravated symptoms. Time out for examination often prevents a seriously disabling injury. However, the acceptance of such responsibility might bring an overbearing interference with squad training if reasonable restraint were not exercised.

As I have seen sprains unnecessarily produced because of certain irregularities in the playing surface, I wish to point out that this danger, particularly in sand-lot competition, has even resulted in fatalities. Improvement in the floor surface of the boxing ring, as a result of changes in rules, has reduced the number of head injuries incident to that sport. In the Eastwood report[2] of fatalities directly caused by football for the 1955 season, 20% were in sand-lot competition. Those responsible for maintenance of grounds must remain alert to the potential dangers of uneven playing surfaces.

Responsibility of Rules Committees and Officials

In October, 1955, the lay press[7] emphasized that the great American football game was developing into a game in which the protective equipment worn by the players might be becoming too heavy and/or too rigid. One could interpret this as suggesting that a player might use his equipment to take advantage of his opponent, offensively or defensively. There is no question that the intent in the designing and developing of new protective equipment is to protect the individual wearer against injury. The various sports rules committees have regulated the hardness of padding that may be worn over certain parts of the body and are always alert to legislate against a particular type of rigid padding used on a particular [illegible] body where it might be utilized as an offen[illegible] on. They act similarly with regard to station[illegible] ment. The rules of boxing were recently [illegible] require a new type of floor matting in the [illegible] which has materially altered the incidence [illegible] head injuries.[8]

Likewise, some years ago the American [illegible] rules committee moved the location of the [illegible] back 10 yards to avert possible injury to [illegible] However, in my opinion, the number of seri[illegible] injuries caused by impact against these [illegible] located on the goal line was not significant [illegible] fessional football in the United States and in [illegible] the posts are still maintained on the goal [illegible] ever, nobody can deny that all are interested [illegible] ing the incidence of injury from body contact. [illegible] taking research on the plastic football helmet [illegible] proper suspension is now being done at Corn[illegible] versity, Ithaca, N. Y., and the University of [illegible] California, Los Angeles. One hopefully looks [illegible] to the ideal design and a reduction in the [illegible] of cerebral concussion.

In body-contact sports today, more respo[illegible] has been placed on contest officials. In baseb[illegible] football the number of officials has been in[illegible] with the idea of better coverage of all facets [illegible] complicated, technical game. The rules and [illegible] tions of all games are complex, but those with [illegible] ber of players scattered over the field require [illegible] fields of vision than are needed in the boxing [illegible] tling ring. Nonenforcement of the rules of the [illegible] spoils the sport, and, in some sports, the sole [illegible] may have too great a responsibility. It is a [illegible] tragedy to report that in 1956, in a freshman pre[illegible] tory school wrestling bout in Springfield, Mass., [illegible] contestant sustained a fracture of the sixth cer[illegible] vertebra and a transected spinal cord. In interco[illegible] iate football too many fouls or infractions of the [illegible] seem to go unnoticed. It is distressing to see in [illegible] game so many instances of broken or displaced teeth [illegible] often occurring in line play. Perhaps the fault lies [illegible] the rules, but perhaps it is the laxity in officiating

Physician's Responsibility

The purely medical prerogative is the diagno[illegible] treatment, and prognosis of all individual injuries [illegible] sustained. In addition, the prerogative pertaining [illegible] the prevention or aggravation of minor injury belo[illegible] to the medical staff. No one can deny that progress [illegible] been made in reducing the days of disability [illegible] athletic injuries. Table 1 demonstrates significa[illegible] the results of early, prompt treatment. Physicia[illegible] trainers, and coaches are all concerned with the individual player and his welfare. The permitting of a player with cerebral concussion to continue play should not be tolerated. Even the player who is exhausted physically and physiologically is more prone to injury if permitted to continue.

A player not mentally or physically capable of carrying out his assignments is of less value to a team than a fresh substitute. Every follower of body-contact sports can recall having seen some player allowed to continue in a rugged contest without full capacity of his mental processes. In the high school leagues particularly, there is lack of adequate medical supervision of practice sessions of contact sports. The responsibility lies in the community schools' committees. According to Eastwood's report[2] of the nine football fatalities in 1955 that were a direct result of competition, six were deaths of high school players. It is unfair to a coach not to provide him with adequate medical assistance. Even though the majority of injuries sustained are not serious, nobody can prophesy when a serious accident might occur.

The team physician must grasp the opportunity to determine whether a limping player should be taken out of competition. He should arrange with the team captain to call time out for any needed examination. He should be familiar with the functional testing of joints, the more common sites of fracture, and the simpler tests for diagnosis of type of injury. In instances of head injuries, he should be alert and ask the player simple questions in order to determine whether there is amnesia, with no orientation of time and place. If necessary the physician could call upon the team captain to interrogate the injured player in order to determine whether the player knew his particular assignment in an individual play signal. When an arm or leg is involved, comparative tests of the normal side and the injured side are simple and very practical.

TABLE 2.—*Types of Injuries Incurred Most Commonly in Sports at Harvard University*

Injury	1932-1937	1937-1942	1942-1947*	1947-1952	1952-1954	Totals
Sprains	636	426	210	344	86	1,702

Miscellaneous	243	152	67	42	6	510
Totals	3,157	1,914	909	1,124	290	7,391

* From fall, 1943, until spring, 1946, the sports were on a wartime basis, with organized sports continued only informally and on a limited scale.

Once the injury is located and diagnosed, its severity or degree is the important decision to make. Will continued play turn a sprain from grade 1 into grade 2 or grade 3? In many instances one cannot determine the degree of injury until 24 hours later. The player should be protected from a possibly long disability period. There is no reason, from the pathological point of view, to think that a sprained ligament can be supported by adhesive strapping, so that the player can be returned immediately to play, without doing irreparable harm to the injured ligament. The torn ligament must heal, and one cannot put stress on it until the healing process is complete, and then only with daily supportive adhesive strapping. It will never again be as strong, since there will be fibrous scarring. The too early return to play of a player with a healing sprained ligament can undo good results of the partial healing process. The team physician must determine when the lesion has healed and the player is ready to return to play. He must realize that, if a player still limps, an ankle sprain is incompletely healed and that, regardless of the amount of adhesive tape applied, the player cannot yet withstand the stress of running and dodging.

TABLE 3.—*Body Distribution of Injuries Incurred in Sports at Harvard University*

Diagnosis and Treatment of Common Injuries

The team physician should become familiar with the more common types of injuries produced in athletics and likewise the more commonly injured parts of the body. Tables 2 and 3 illustrate my own experience. Alertness on the part of the trainer and team physician and recognition of the more serious and less common injuries is a "must" in organized sports. In most body-contact sports, there is a time limit of three minutes in which the one responsible for diagnosis and prognosis must decide whether an injury is of sufficient degree to require the player to leave the field.

Sprains, strains, and contusions account for over 60% of the injuries sustained in competitive athletics (table 2). A full knowledge and understanding of the pathology[9] of such lesions is necessary for all team physicians. Diagnosis and prompt institution of appropriate treatment are the key to a reduction in the

STUDY OF THE LONGEVITY AND MORBIDITY OF COLLEGE ATHLETES

Henry J. Montoye, Ph.D., Wayne D. Van Huss, Ph.D., Herbert Olson, M.S., Andrew Hudec, M.S.
and
Earl Mahoney, M.S., East Lansing, Mich.

• *When 629 athletes were compared with 583 nonathletes with approximately the same college environment, there appeared to be no significant difference in life expectancy, cause of death, or the type of death. The criterion of being called an athlete in this survey was to have been a varsity-letter winner. This particular study is in agreement with other recent studies of a similar nature.*

The effects of intensive athletic competition on the heart and other organs and on bodily resistance to disease has long been a subject of controversy. Previous to the work of Morgan [1] in 1873, the viewpoint prevailing in England was that competitive oarsmen did not live beyond 50 years of age and that this reduced longevity was directly caused by athletic competition. The studies of Morgan [1] and Meylan [2] in 1904 refuted this concept. Attempting to gain further insight into the longevity of athletes, Anderson [3] and Greenway and Hiscock [4] compared the longevity and causes of death of Yale University athletes with use of insurance tables. Dublin,[5] Knoll,[6] Hartley and Llewellyn,[7] and Wakefield [8] similarly compared their data on athletes with insurance company or general population statistics. Bickert,[9] Van Mervennée,[10] and Schmid [11] added to the body of information available on the longevity and morbidity of athletes but presented no control data. Hartley and Llewellyn [7] point out that athletes are a select group and that, therefore, comparisons with data of life insurance company tables are open to serious criticisms. Dublin [5] stated that a comparison of athletes with their classmates might yield more valid information.

Dublin's [12] second study in 1932 and Rook's [13] work in 1954 represent perhaps the best analyses in the literature on the longevity and causes of death among athletes and nonathletes. Dublin's results show the expectation of life in years at age 22 for honor men (47.73) to be greater than for either the average graduate (45.71) or the athlete (45.56). All college groups, however, showed greater life expectation at age 22 than was listed in tables covering the period 1900-1915 for American men (44.29) or was given for American white males listed in the 27 registration states of the United States for 1919-1920 (43.35). Rook's results as to longevity varied from Dublin's, in that the average age of sportsmen at death (67.97) exceeded that of the randomly selected group (67.43) in his study. The intellectual group again, however, had the greatest longevity (69.41). In all studies in which causes of death were investigated, deaths by external violence among athletes markedly exceeded those among controls. Typically, Wakefield [8] in 1944 found 34% of all deaths among former basketball players were due to external violence, as compared with 17.3% for the general population of the state of Indiana. Rook found the death rate due to external violence to be 97.9 per thousand for sportsmen, as compared with rates of 46.7 for intellectuals, and 70.4 for his random group.

The results of studies regarding comparative rates of death due to cardiovascular causes do not indicate clear trends. In Rook's [13] study for instance, 27.3% of the deaths before age 65 among controls were due to cardiovascular conditions, as compared to 22.5% among sportsmen. Wakefield's [8] results, on the other hand, showed 25% of all deaths caused by disease to be due to cardiovascular-renal diseases, as compared to only 16% for the general population of Indiana. Dublin's [5] results in 1928 showed that, of all deaths among athletes over 45 years of age, 32% were due to heart disease, as compared with a rate of about 20% of the total deaths among insured groups from this cause.

Present Study

The present study was undertaken as a pilot study of the larger national research project inaugurated in 1951 and sponsored by the physical education honorary fraternity, Phi Epsilon Kappa. Questionnaires prepared by a national study committee were sent out to 1,130 former athletes and 1,130 others not former athletes, individually matched as to years of attendance at Michigan State University and ranging in dates of birth from 1855 to 1919. (For purposes of this study, athlete is defined as a letter winner in a varsity sport.) Of the 2,260 questionnaires sent out, 1,212

Associate Professors (Drs. Montoye and Van Huss), Instructor (Mr. Olson), and Graduate Assistants (Messrs. Hudec and Mahoney), Health, Physical Education, and Recreation Department, Michigan State University.

Read before the third Annual Convention of the American College of Sports Medicine, Chicago, April, 1956.

were returned with sufficient information to be included. Six hundred twenty-nine, or 55.66%, of the questionnaires sent to athletes were returned, as were 583, or 51.59%, of those sent to the control group. The distribution of returns by year of birth shown in figure 1 would seem to indicate that comparisons are justified with respect to longevity or causes of death. Data from the questionnaires were tabulated, punched onto IBM cards, and analyzed, insofar as possible by IBM techniques. The data have been statistically analyzed where appropriate (tables 1 and 2). One hundred twenty-three, or 9.85%, of the total returned questionnaires were for deceased subjects, of whom 67 were athletes and 56 controls. Since this was a questionnaire study and, hence, subject to response error, particularly with regard to cause of death, it was decided to determine the validity of the responses. Therefore, data from the death certificates were obtained in 104 cases. List B of the "Manual of the International Statistical Classification of Diseases, Injuries, and Causes of Death" [14] was used for the classification of the causes of death. Errors in the causes of death were classified as major, minor, and those of insufficient information. A major error was listed when the questionnaire response was not pathologically related to the cause of death on the death certificate. A minor error indicated that the response and the actual cause were related pathologically although classified differently in the international classification.

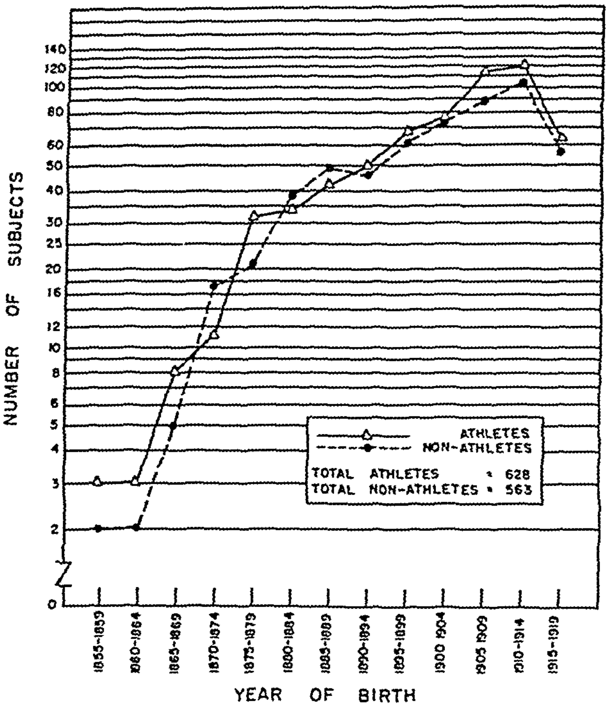

Fig 1 —Distribution of years of birth of athletes and nonathletes included in study

TABLE 1 —*Comparison of Athletes and Nonathletes, by Selected Characteristics*

Characteristic	Athletes, %	Nonathletes, %
Service in armed forces*	66.4	55.8
Branch of service*		
Army	70.1	82.7
Navy	23.2	13.9
Marine Corps	2.8	
Other	3.9	3.4
Activity in service		
Mild	13.7	18.9
Moderate	50.4	53.9
Vigorous	35.9	27.2
Married	96.9	97.0
Drinker*	77.6	66.5
Smoker*	68.7	60.2
Weight in college*	164 lb	153 lb
Weight gain since college	9.7 lb	10.4 lb

* These differences are statistically significant, i. e., it is unreasonable that chance would account for them

The validation results, in which the data from death certificates and the questionnaires were compared, were as follows: 1. In dates of birth, agreement was very good. Only 10 discrepancies were noted, with a mean error of 0.35 years, which was not statistically significant. 2. In ages at death, agreement was good. Twenty-two discrepancies were noted, with a mean error of 0.32 years, which also was not statistically significant. 3. Nineteen discrepancies were noted in causes of death. Two were major errors, 13 minor errors, and 4 were cases in which insufficient information was available to make a decision. Most of the errors noted concerned cardiovascular causes, particularly heart disease. While the layman is apparently oriented to the term heart disease, the death certificate might list the cause of death as coronary thrombosis or angina pectoris, which technically, for classification purposes, is erroneous. Because of this, fine classifications of causes of death from conditions of the cardiovascular area were not possible. Coarse classifications, however, were affected very little when questionnaire and death data were compared (fig 2).

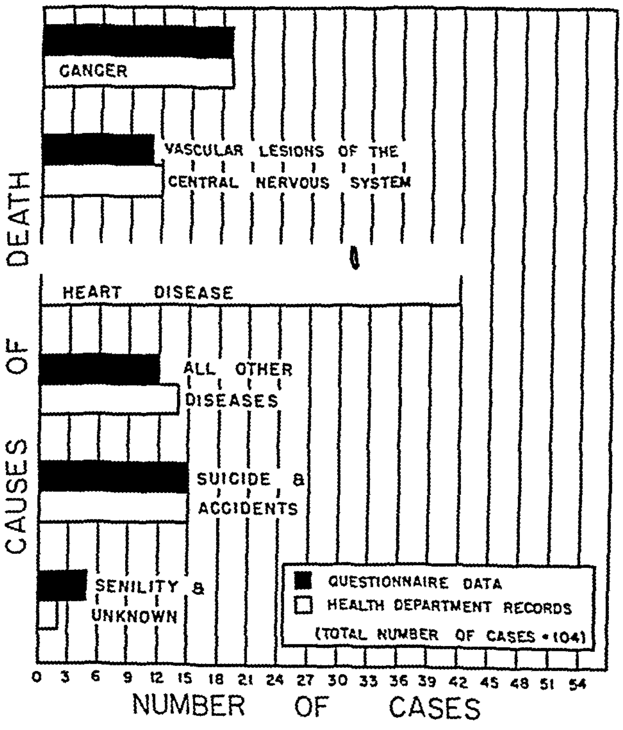

Fig 2 —Comparison of data on cause of death received from questionnaires used in study and of data from state health department records

The age at death of the athletes and nonathletes is compared in table 2. The difference in actual and expected age at death is not surprising, when we consider how highly select the men in attendance at college were during these years. Also, since the percentages of returns of the questionnaires in the two groups were 55.66 and 51.59, it is quite probable the sample became even more select due to the difficulty in obtaining data on those who died in the earlier years. What is of interest here, however, is that there is little difference existing between the two groups. This is in agreement with the studies by Dublin[12] and Rook.[13] Differences between the athletes and nonathletes in the distribution of causes of death, type of death (sudden or lingering), and causes of death of parents were statistically insignificant.

TABLE 2.—*Comparison of Age at Death of Athletes and Nonathletes*

	Mean Life Expectancy, Yr.*	Mean Age at Death, Yr.†	Difference, Yr.
All deaths included			
Athletes	65.96	73.86	7.90
Nonathletes	65.97	71.24	8.27
Excluding accidental deaths			
Athletes	65.96	74.43	8.47
Nonathletes	65.99	74.59	8.60

*Computed for the time when the athlete or nonathlete was in college, using the appropriate mortality tables.

†Actual ages of death were used where death had occurred. Otherwise this represents the individual's present age plus remaining years of life predicted from current mortality tables

Summary

The questionnaire method was employed in securing data on former college athletes (letter winners) and nonathlete controls. The results indicated that the longevity of athletes was approximately the same as that of controls and the distribution of causes of death was very similar. A significantly greater percentage of former athletes served in the armed forces and, of those serving, a significantly larger proportion served in the Navy and Marine Corps. A significantly greater percentage of former athletes smoked and drank, and their weight in college was appreciably greater. There were no significant differences in the number married, weight gain since college days, or strenuousness of activity while in the armed services.

THE PHYSICIAN AS A SPORTSMAN

Allan J. Ryan, M.D., Meriden, Conn.

• *The physician's interest in sports is twofold, for he may participate actively or he may be enlisted as an adviser on hygiene to athletic organizations or as a specialist in the treatment of athletic injuries. Several societies devoted to sports medicine exist, and important research is being done in this field. Physicians have also distinguished themselves as participants in many varieties of sport. It is necessary for the physician to adapt these activities to his changing capacities as he grows older. He may be inclined to exert himself immoderately after long periods of athletic inactivity and to view physical conditioning as a nuisance. His problem is to find time for frequent, regular, and moderate physical exercise and for relaxation and companionship. The many examples here given show that the problem can be solved.*

"It is very difficult for a physician in general practice to get a reasonable amount of exercise and play. He cannot take the time for golf, he dare not make a definite appointment with an opponent for tennis, and he must keep in communication with his office." Thus reasoned quite a few years ago a Dr. Weston, who was leading up to the fact that his favorite sport of archery could be readily practiced by a physician in spite of such inconveniences. In this present day of office hours by appointment, increased specialization, partnership and group practice, and a degree of prosperity that allows the physician to take time off when he feels like it, these difficulties may not seem to pose a serious problem.

Perhaps the thing that concerns the average physician today is not so much whether he can take time off for sports recreation but what sport he will find it best to pursue. The range of possibilities is wide and is limited chiefly by his preference and his pocketbook. Whether he believes in the therapeutic or the prophylactic values of exercise, he may be concerned as to whether he will overtax himself, particularly since his opportunities for recreational activity may increase as he advances in years. In this event, he might be more interested to hear from another sports fan, John DeVinne Singley of Pittsburgh, who has said, "It is essential that the heart muscle should not be overtaxed while exercising. Choose a type of exercise suitable to your years if you would derive benefit from it. As a physician, and from personal experience on the bowling green, I recommend lawn-bowling unreservedly."

Such evidence as is available indicates that, in the United States at the present time, there is no group of professional men that devotes more time to a greater variety of sporting and athletic activities than physicians. Although governing bodies of the various sports federations do not keep separate records of their membership according to occupation, the accumulated observations over a long period of time of interest in all sports, particularly with regard to record-breaking activities, coupled with a multitude of replies to a public appeal for information regarding the sports activities of physicians, have produced a sort of cross-sectional view of the extent of participation by our medical colleagues.

Professional Sports Medicine Groups

The great interest that many physicians have taken in the physiology of athletics is signalized by the organization and growth of such organizations as the International Federation for Sports Medicine (FIMS), the British Medical Sports Association, the American College of Sports Medicine, and the Western Council of Sports Medicine. The purpose of such organizations can best be summarized in the aims of the international federation: "To contribute toward the progress of medical sciences by the study of medico-athletic problems; to take all necessary steps for insuring that its conclusions are applied in all athletic and gymnastic activities."

The federation was established at St. Moritz, Switzerland, in 1928 and has since held congresses at Amsterdam, the Netherlands, in 1928; Turin, Italy, 1933; Chamonix, France, 1934; Berlin, Germany, 1936; Paris, France, 1937; Brussels, Belgium, 1939; Prague, Czechoslovakia, 1948; Montecatini, Italy, 1950; Paris, France, 1952; and Belgrade, Yugoslavia, 1954. It comprises a general assembly and an executive committee. Each national medical sports association appoints one delegate to the assembly. There are also guest members, one of whom is chosen for each country by the executive committee, and members of the executive committee, who are not national representatives. The executive committee, which is elected for a period of four years, meets every year. The congress of the general assembly is held every two years. It is supported partly by the host government and by members' subscriptions. There is a monthly official bulletin, *Studi di medicina e chirurgia dello sport*. National association members currently come from the following countries: Argentina, Austria, Belgium, Brazil, Czechoslovakia, Finland, France, Germany, Iran, Italy, Japan, Luxembourg, the Netherlands, Norway, Poland, Rumania, Spain, Sweden, Switzerland, the U. S. S. R., the United Kingdom, Venezuela, and Yugoslavia.

It may seem strange that our own sports-loving country is not represented in the federation by a national association, but there are some individual members from the United States. The closest thing we have to such an organization is the American College of Sports Medicine, which was founded April 23, 1954, for the following purposes: (1) to promote and advance scientific studies dealing with the effect of sports and other motor activities on the health of human beings at various stages of life; (2) to cooperate with other organizations concerned with various aspects of human fitness; (3) to sponsor meetings of physicians, educators, and other scientists whose work is relevant to sports medicine; (4) to make available postgraduate education in fields related to the objectives of the college; (5) to initiate, encourage, and correlate research; and (6) to publish a journal dealing with scientific aspects of activity and their relationship to human fitness.

Meetings of the college are held annually and alternately on the occasion of the annual meetings of the American Association for Health, Physical Education, and Recreation and of the American Medical Association. The third annual meeting was held in March, 1956, in Chicago. The membership is classified as fellows, associate fellows, members, affiliate members, and student members and is open to doctors of medicine, education, physical education, and public health, and to those holding master of science or arts degrees in fields related to physical education and biology. There are at present 78 fellows, 2 associates, 12 members, and one affiliate. A similar organization, the Western Council of Sports Medicine, was established in California in 1955. Although active membership is limited to physicians, laymen whose interest lies in this field are welcomed as associate members.

Participation in Sports

However, for every physician who carries his interest as far as joining such an organization, there are thousands who participate in sports either for exercise, recreation, relaxation, companionship, or simply because they enjoy competition. Some of the most enthusiastic sportsmen among the physicians are those well known to their colleagues because of their eminence in medicine and in other fields. Arthur Conan Doyle, who achieved fame as a writer, participated also in cricket, billiards, football, auto racing, sailing, rifle shooting, golf, and boxing. That remarkable American sage, Benjamin Franklin, who, although he did not hold a medical degree, was a member of several medical societies, including those of London and Paris, wrote many times on matters of public health and medicine and had a profound influence on medical thought in his day. He was an enthusiastic and accomplished swimmer.

There is probably no branch of sport that does not number among its participants physicians in the making, in medical school or postgraduate training, or in active practice. A surprising number have combined for a time the beginnings of a medical career with professional athletics. Naturally, those sports that depend on individual and unorganized participation draw the greatest numbers of physicians. The largest group of active participants are those who engage in hunting and fishing. The American Field Publishing Company states that there are more than 2,500 physician members of 300 registered organizations holding 600 or more pointer field trials in the United States every year. Regular or occasional fishermen among the profession are estimated to number between 40,000 and 50,000.

The taste of physicians as far as participation in sports is concerned seems to follow the national taste among adult males in comparative age groups. There is no one activity that seems to be particularly associated with the profession. The many physician golfers and proportionately fewer tennis players seem to follow the national average for participation in these sports, if allowance is made for the relative economic status of the two groups. The ability to belong to the local country club makes these sports more available for the physician, which compensates for the smaller amount of time he may be able to spend on them. Very few physicians apparently undertake sports or maintain their interest in them as part of a conscious program for maintaining or achieving physical fitness. Rather, they are inclined, when free to do so, to exert themselves immoderately after long periods of athletic inactivity. They also tend to ignore the importance of diet and abstinence (alcohol and tobacco) as preparation for athletic activity and to view physical conditioning by gymnastics as outmoded, impractical, and just a nuisance.

Outstanding Performers

In spite of this, the roll of champions and outstanding performers in all sports activities includes many who have achieved this eminence during their medical careers. The following list, with the sports enumerated in alphabetical order, indicates the names and accomplishments of those who have come to my attention. I make no pretensions of being all-inclusive and tender my apologies in advance to all those who are unknown to me or who have been overlooked or inadvertently omitted.

Archery.—Since archery as a sport has evolved from hunting, it is one of the oldest sports known. It made its appearance in the United States as an organized sport in 1828, when the Club of United Bowmen was founded in Philadelphia with Drs. Robert Eglesfield, Robert E. Griffith, and Samuel Griffith Jr. taking part. Since that time many physicians have participated in and achieved eminence in this sport. Henry B. Richardson of Boston was winner of the Grand National Title of Great Britain in 1908, J. W. Doughty of Washington won the American National Archery Title in 1913, and Erwin Pletcher was the National Field Archery Champion in 1949. Robert P. Elmer won many archery championships between 1911 and 1922 and has produced several authoritative books on the history and practice of archery. Other outstanding competitors have been O. L. Hertig of Pittsburgh, Saxton T. Pope of San Francisco, H. G. Goldberg of Philadelphia, B. L. Rawlins of Chicago, I. V. Cole of Seattle, H. T. Elliot of New York, and C. S. Case.

Auto Racing.—Since road racing in sports cars is essentially for the young man, one does not find too many physician racers. Probably the outstanding competitor at the present time is Sherwood Johnston of Greenwich, Conn. Among other victories he numbers the President's Cup Race at Hagerstown, Md., and the eighth annual sports car *grand prix* at Watkins Glen, N. Y., where he drove his D-Jaguar last year at an average of 81.92 miles per hour.

Baseball.—Participation in baseball after college days is practically limited to semiprofessional or professional leagues today. D. L. Adams and James R. Purdy were members of the old Knickerbocker Baseball Club in New York, one of the last strongholds of the amateur game. Medicine's outstanding competitor in professional baseball is Tommy Brown, who played third base for the New York Yankees to pay his way through medical school and internship.

Basketball.—The sport of basketball is also primarily professional after college competition and, because of the peculiar traveling requirements and long season, virtually excludes medical men. Al Van de Weghe of the New York Knickerbockers, however, helped to finance his medical education for several years while playing in the toughest professional competition.

Billiards.—While some may question the inclusion of billiards as a sport, it has always been reported as such. Apparently no physician has ever excelled as a professional, but the amateur three-cushion championship was held for three consecutive years by two medical men, A. J. Harris in 1925 and 1926 and L. P. Macklin in 1927.

Boxing.—It is a matter of interest that the only amateur ever to hold the world's heavyweight boxing crown was a physician. "Gentleman Jack" Jackson of England gained the world championship in 1795 and retired undefeated. He later opened a boxing school and taught Lord Byron, among others.

Court Tennis.—The most ancient and most intricate of all the racket and ball games, court tennis, still enjoys a limited patronage today in the United States as well as abroad. Many physicians in the eastern part of the United States have played this game of kings. Probably the most proficient were two from Boston, Channing Frothingham and G. S. Derby.

Fencing.—The sport of fencing has always attracted the interest of physicians. In the United States the names of B. F. O'Connor, Graeme M. Hammond, who founded the American League of Amateur Fencers, and Norman C. Armitage and John R. Huffman, who represented the United States in Olympic competition, stand out. Huffman accomplished a remarkable achievement for a non-European when he took sixth place in the saber event at the 1932 Olympics. Tibor Nyilas of Elmhurst, N. Y., has been seven times national saber champion.

Field Trials.—As previously indicated, the breeding, training, and hunting of dogs is a principal preoccupation of many members of the medical profession. A few of those outstanding in recent years have been Samuel Orr Black of Spartansburg, S. C., John H. Powers of Cooperstown, N. Y., past Grand National Grouse Hunting Champion, Frank H. Lahey of Boston, holder of the National Quail Championship in 1928 and 1934, Harold E. Langsdorf, Mount Holly, N. J., five times holder of the American Pheasant Championship and holder of the National Pointer

Championship in 1954, and Francis Record Whitehouse of Lynchburg, Va., winner of the National Beagle Club's annual field trial in 1955.

Fishing.—Since fishing is not for the most part a competitive sport among the fishermen, but rather a contest between man and fish, it is hard to pick out fishing "champions." Among the thousands of medical fishermen who have enjoyed this recreation in its many varieties may be mentioned two who were national champions in flycasting, E. A. McFarland and E. A. Fogle, and two whose record catches do not seem at first so remarkable but have stood for a long time in the record book of fishing. C. A. Abbott at Bordentown, N. J., in 1865 caught the largest yellow perch ever taken in fresh water, 4 lb. 3½ oz. W. J. Cook in 1916 in the Nipigon River in Ontario took the largest brook trout ever caught, which weighed 4 lb. 8 oz.

Football.—In the days when amateur football teams represented the university rather than simply the college, there were quite a few players who continued to be active while in medical school. The three-year rule today and the revival of professional football have limited the possibilities for physicians' participation. Nevertheless, two outstanding all-American players played the professional game to support their medical studies, both, strangely enough, for the Chicago Bears. Daniel J. Fortmann, now a surgeon in Hollywood, Calif., starred for at least five years after being all-American at Colgate University in 1935. William J. McColl, an all-American selection while playing for Stanford University in 1950-1951, has played for the Bears more recently. Medicine has made a unique contribution to football in the number of men who have undertaken college coaching. Clarence W. Spears, all-American at Dartmouth College in 1914-1915, coached for many years in the Big Ten. George W. Hauser, all-American at the University of Minnesota in 1916-1917, coached for many years afterward and is now a dermatologist in Minneapolis. The longest current coaching tenure of any physician coach is that of Edward N. Anderson, all-American at the University of Notre Dame in 1921 and now head football coach at Holy Cross. Marvin A. (Mal) Stevens was all-American at Yale University in 1923 and subsequently coached at the university, at New York University, and for the U. S. Naval Training Base at Sampson, N. Y. He is now an orthopedic surgeon in New York.

In the field of Rugby football, a remarkable record is held by Leonard Stokes of Guy's Hospital, Oxford, England, who drop-kicked an 80-yd. field goal while playing for England in an international match in the 1880's. A current star of Gaelic football is James Brosnan, now of New Rochelle, N. Y., who is a member of the County Kerry team that won the All-Ireland Championship in 1955 and that played in New York in 1956.

Golf.—Golf has the distinction among other sports of providing a semiofficial part of the program of the American Medical Association's Annual Meeting and of many other medical meetings. The American Medical Golfing Association held its 40th annual tournament June 11 in Chicago. All male members of the A. M. A. are invited to join this organization. Although thousands of physicians play golf every year, we have never produced as distinguished a champion as the dentists' Cary Middlecoff, now a professional. W. Tweddell, an Englishman, won the British Amateur Golfing Championship at Hoylake in 1927 and was one of the game's distinguished amateur players. Frank Deighton reached the quarterfinals of the same tournament this year. There are many eminent medical golfers who compete in the American National Senior Championships each year, among whom is former champion Ralph Nichols of New Haven, Conn.

Horsemanship.—Although many physicians ride for enjoyment and exercise, very few are active in equestrian competition. Benjamin Rush recommended riding very highly to his patients. John Yarbrough of Los Angeles is the head of the group who call themselves "Los Charros," who ride each year with Los Rancheros Visitadores.

Hunting.—Fox hunting has claimed the allegiance of many physicians in the United States as well as in the British Isles. Probably no one in this country has a more remarkable record of devotion to this sport than Misch Caspar of Louisville, Ky. He has been a winner of many trophies between 1906 and 1953 and during this time has owned over 2,000 foxhounds. Ira H. Rapp of Charlottesville, N. C., and Joseph F. Shuffield of Little Rock, Ark., are other notable exponents of this sport. Big game hunting and fishing attract many medical men. Some roam the entire world in pursuit of their hobby. Among the notable participants from the United States are Theo S. Stashak of Santa Rosa, Calif., Herbert J. Movius of Hollywood, Calif., and P. L. Riddell of Williamsport, Pa.

Lawn Bowling.—Lawn bowling is a rather old sport that maintains a steady popularity among a relatively small group of devotees. John DeVinne Singley of Pittsburgh, who was quoted earlier, is singles champion of his club. Raymond W. Sendker of Buffalo was Lakeside Doubles Champion in 1955 and has held several national championships.

Mountain Climbing.—The sport of mountain climbing claims the interest of physicians not only as a hobby but because it is considered essential today for all big expeditions to the Himalayas to have at least one physician climber as a member of the party. The British expedition that scaled Mount Everest in 1953 included three physicians, Michael Ward, chief medical officer, L. G. C. Pugh, medical physiologist, and R. C. Evans, who went with the final assault team. Stafford Matthews of Edinburgh, Scotland, a gynecologist, participated in the assault on Kanchenjunga and L. Bruce Meyer was on the 1954 climb of Makalu. Charles S. Houston of Exeter, N. H., was a member of the party that attempted to climb Nanda Devi in 1936 and led the unsuccessful attempt to scale Godwin Austen, or K^2, in 1953. Other noted American climbers are Benjamin G. Ferris and William F. Loomis, Boston, Roger S. Whitney, Colorado Springs, Colo., and Henry A. Buchtel, Denver.

Pistol Shooting.—J. R. Calkins of the United States was a member of the winning revolver and pistol team shooting at 50 and 100 yd. at the 1908 Olympic Games in London. Reginald Sayre of New York competed in many pistol-shooting events with notable success.

Polo.—Because of the restricted opportunities, elaborate equipment, and time required to play polo, few physicians have been known as polo players. A notable exception is Hugh B. Blackwell of New York, who represented the United States on one occasion in international competition.

Skin Diving.—Skin diving is one of the newest of all sports, but it already numbers many physicians among its followers. Two who have been interested in the medical problems involved are William T. Burns and Gordon Bateman of Long Beach, Calif.

Squash Rackets.—Squash rackets is the closed court game that has achieved the widest popularity in this country and throughout the British Empire. Notable physician players from the United States have been George M. Converse, Robert Dam, and William K. Miller of Philadelphia and Laurence M. Hutner, now of Los Angeles but city champion of Rochester, N. Y., from 1938 to 1942.

Squash Tennis.—Squash tennis has never been popular except in the northeastern United States. Alfred Stillman of Boston was the first national amateur champion and ruled in 1911, 1912, and 1914. H. R. Mixsell of New York was veterans' champion many times. In more recent years, Daniel C. Patterson of Bridgeport, Conn., and C. J. MacGrime of New York have been outstanding players.

Swimming.—Medicine has produced three Olympic swimming champions from the United States. G. E. Sheldon won the Olympic springboard diving championship in 1904. George Kojac, formerly of Rutgers University, in the 1928 Olympics won the gold medal in the 100-m. backstroke, was fourth in the 100-m. free style, and swam on the 800-m. relay team, which took first place. Major Sammy Lee, ophthalmologist in the U. S. Army Medical Corps, was Olympic diving champion from the high platform in 1948 and 1952 and climaxed his career in 1953 by becoming the only physician to win the James E. Sullivan Memorial trophy for being the outstanding amateur athlete of the year in the United States.

Table Tennis.—Table tennis has many physician players, but there are very few who enter competition. A successful competitor is Peter Fisher of Seattle, who formerly shared the Pennsylvania State Men's Doubles Championship and last year shared a similar title in Seattle.

Tennis.—The physician to be best known as a tennis star was probably James Dwight of Newport, N. Y., who five times, between 1882 and 1889, shared the national men's doubles championship. Undoubtedly the best tennis player–physician is David G. Freeman of Pasadena, Calif., who was once ranked no. 4 nationally in singles. Reginald Weir of New York has consistently ranked high in his district, as have Paul Newton of Oakland, Calif., and Peter Fisher of Seattle. J. A. Crane of Berkeley, Calif., was in 1955 ranked, with his son, Michael, no. 1 in father and son doubles by the United States Lawn Tennis Association.

Track and Field.—Some of the most outstanding athletic achievements of physicians of all time have been in track and field competition. Paul Martin of Switzerland won the silver medal in the 800-m. run at the 1924 Olympics while a medical student. Patrick O'Callahan of Roseville, Tipperary, Irish Free State, is the only physician to have won the gold medal twice in the Olympics, having been the champion in the hammer throw in 1928 and 1932. John E. Lovelock of New Zealand won the Olympic 1,500-m. run in 1936 and was also holder of the world's outdoor records for the mile as well as for 1,500 m. Arthur Wint of Jamaica, West Indies, won the gold medal in the 400-m. run in 1948 while a medical student. Roger Bannister, now of Guy's Hospital, Oxford, England, a keen student of the psychology and physiology of distance running, was the first man to run the mile in less than four minutes. Although he soon lost the world record to John Landy of Australia, he was able to beat Landy in near-record time in their famous race at the British Empire Games in Vancouver, British Columbia, Canada.

Although the United States has not produced any physicians who were world champions in track and field, we do have two noted competitors. Charles Robbins of Middletown, Conn., is the holder of 11 national titles in long-distance running events. He twice has been winner of the five-mile road race at Manchester, in which he competes annually. John Kingsley Lattimer, formerly of Columbia College and now professor of urology at Columbia University College of Physicians and Surgeons, held the Amateur Athletic Union 200-m. hurdles record for 12 years. He won the Millrose Games 50-yd. dash while a student at the latter college and later, while serving in the U. S. Army in Europe, he won the hurdles championship for the Seventh Army in the G. I. Olympics.

Yachting.—Sailing and powerboating rank high in the esteem of several thousand physicians in the United States. Britton Chance of Philadelphia became our only Olympic gold medal winner in this field when he sailed his 5.5-m. yacht to victory in 1952 at Helsinki, Finland. C. Darwin Jurss of Milwaukee won the Great Lakes sailing championship in 1936 and Benjamin Sawyer of Middletown, Ohio, won the Highlander National Class Championship in 1955. Some sort of transatlantic record was recently set by Hans Lindemann of Germany, who crossed this year alone from Liberia, Africa, to Haiti in 65 days in an overdecked canoe.

Malignant Tumor Cells.—The structural pattern of a malignant tumor cell is sufficiently distinct from that of the normal cell to be readily identified in most instances even when viewed as an individual cell. The study of exfoliative cytology on which we depend for early recognition of cancer is based upon these observations. The changes most helpful for diagnosis of a tumor cell are nuclear, although cytoplasmic pattern, even in the light microscope, sometimes determines the type and source of the abnormal cell. The nuclear aberrations, the decreased cytoplasmic nuclear ratio, the coarser, more irregular chromatin pattern, the large, more numerous nucleoli, and heavier nuclear membrane are features in daily diagnostic use. No two tumors are alike and there is characteristically great cellular variegation in a single tumor, yet most tumors have certain morphologic features in common that are sufficient to enable us to say, "These look like cells of a malignant tumor."—E. E. Sproul, M.D., Particulate Components of the Cytoplasm, *Laboratory Investigation*, March-April, 1956.

RELATIONSHIP OF PHYSICAL FITNESS TO ATHLETIC PERFORMANCE AND SPORTS

Thomas K. Cureton, Ph.D., Urbana, Ill.

• *Physical fitness leads to better athletic performance, and persistent training will usually develop physical fitness. Detailed analyses of the anatomic and physiological characteristics of famous athletes show that it is possible to make fairly reliable predictions of athletic performance. Scores obtained by various static and dynamic tests exhibit various degrees of correlation with the scores made in competition, and it has been easy to pick out the tests that give the highest coefficients of correlation. Dynamic tests thus are shown to have higher predictive value than static tests. Type of physique, strength and power, respiratory efficiency, and cardiovascular components are among the factors that determine performance, but no two, or three, or four factors, even when combined in an optimum manner, measure all aspects of fitness. Fitness tests applied to former champions gave the best results in those athletes who were in continued training. Endurance training makes marked improvements in cardiovascular function. Ability of the endurance athlete to use oxygen is related to circulatory and respiratory capacity, but in sprints, weight lifting, and swimming there are many other important specifics.*

The relationship of physical fitness to sports is a two-way connection. Physical fitness surely leads to better athletic performances, and persistent repetition of daily training will usually develop physical fitness according to the character of the sport concentrated upon. The training for various sports differs, inasmuch as distance running is different from power performances, as in the high jump, shot-put, short sprint, or discus throw, and swimming 400 m. (as has been done by Boiteux, Hashizumi, and Konno) is different from pistol shooting, wrestling, or weight lifting. Success in such individual events depends upon the optimum combination of mental attitude, skill, and fitness. The great champion is apt to have these qualities and also the right body for the event. These characteristics should be illustrated to make them clear. Let us consider the types of fitness shown in two great athletes, Emil Zatopec and Roger Bannister.

Emil Zatopec has a lean, medium build (68.6 in. [174.2 cm.], 149.5 lb. [67.8 kg.]), with mesomorphic legs somewhat longer than usual and rather small (almost ectomorphic) chest and arms, and obviously carries an extremely small amount of dead weight. His legs are unusually strong. In his 5,000-m., 10,000-m., and marathon victories at Helsinki, Finland, in 1952, the peculiar nonuse of his arms, beautiful evenness of leg action and relaxed flatfoot style in his fairly short stride, and tantalizing head-turning and facial grimaces were interesting to watch, but in the last third of each race he left his competitors, with demonstrations of endurance that astounded everyone. The seven-year (1945-1952) laboratory record from Prague, Czechoslovakia, made available to me by Jiri Kral, shows his steady improvement in circulatory-respiratory capacity, which reached a climax at Helsinki. The scientific report states, "Zatopec improved and strengthened his natural somatic qualities with industrious training and with exercise until he reached his advantageous constitution of today . . . he went through and is constantly going through perfect many-sided physical training, which in the last analysis is the most important and deciding factor in the case of peak endurance sportsmen." It is remarkable that he did not even interrupt his training for military service. In the winter he ran in heavy boots in the forest or along some road. He trained both winter and summer. One minute after a 5,000-m. race in 1947, his blood pressure was 210/30 mm. Hg and his pulse rate 148 beats per minute. Before the race his blood pressure was 142/80 mm. Hg and pulse rate 68. In 1949, after his 10,000-m., world record run of 29 minutes, 21.2 seconds, his blood pressure one minute after the race was 160/40 mm. Hg and his pulse rate 150 beats per minute.

Kozik described Zatopec's "victory of the will" in 1949 and told of Zatopec's practicing breath-holding to train his will as he walked to work, counting poplar trees along the side of the road. He struggled with breath-holding day after day, "until he felt pressure in his head, weight on his chest, felt himself choking and felt like he was losing consciousness—then he fainted and dropped to the ground." Thus, Zatopec trained his will. Any runner who beat him had to beat such a will, not only a style of running or a body type. In 1951 and 1952 he trained by breathing oxygen mixtures and cultivated the relaxed upper-body style that enabled him to breathe the best. Such breathing of oxygen has been cited by A. V. Hill and Roger Bannister as being a possible means of conditioning the lung epithelium (through which oxygen and carbon dioxide must pass). In respiratory values, Zatopec had much higher than average values in volume of maximum ventilation, and, over four years of training, he increased the value for frequency of ventilation during exercise to three times that at rest. Seliger showed his pulse curve to be of the strong sympatheticotonic type. We have shown the same (fig. 1).

The results of tests made in 1951 by Hornof and Kremer in Prague showed an amazing ability of Zatopec's blood circulation to adapt to exertion. In the Harvard five-minute step test, the three pulse rate counts taken (after five minutes of stepping onto a 20-in. bench at the rate of 30 steps a minute) at from 1 to 1½, 2 to 2½, and 4 to 4½ minutes after the exercise period were 27, 29, and 31 beats, totaling 87 beats. In our records, only Bannister has recorded as good a test. In 1951, in the Flack test, Zatopec blew with a force of 40 mm. Hg for 60 seconds. After 30 step-ups in a minute, using a chair, he blew for 55 seconds. These figures are at the very top of our scales. In the report of Hornof and Kremer, the data on oxygen intake during the effort are missing, so we have only a partial fitness report.

Roger Bannister demonstrated some remarkable measurements of fitness when we tested him in London, England, in May and June, 1952, at the Royal Free Medical College. In the regular Harvard five-minute step test, his pulse rate was 108 beats per minute within the first 15-second interval after the effort, and there were 29 beats in the 1 to 1½-minute recovery interval, 29 beats in the 2 to 2½-minute interval, and 29 beats in the 3 to 3½-minute interval, totaling 87 beats. This equaled Zatopec's score. So far as we know, these are the two best records on this test. On another day Bannister performed remarkably in our "all-out step test," doing 40 steps per minute on a sturdy chair, 17 in. in height. At 5¼ minutes he was almost "all-out," as his legs began to tire obviously. We were using a large single Douglas bag to collect his exhaust gas. When this was full, we stopped him. Throughout the test he had the two-way valve in his mouth and his nose was clipped. In the first 15 seconds after this test, his heart rate was 120 beats per minute, which we consider remarkable. His systolic blood pressure after one minute was 170 mm. Hg, and his diastolic pressure was 60 (phase 4). The significant points are his extremely low pulse rate of 120 beats per minute and the drop of his diastolic pressure from 78 while lying (systolic was 114) to 60 mm. Hg (phase 4) while sitting (his pressure while standing was 124/86 mm. Hg).

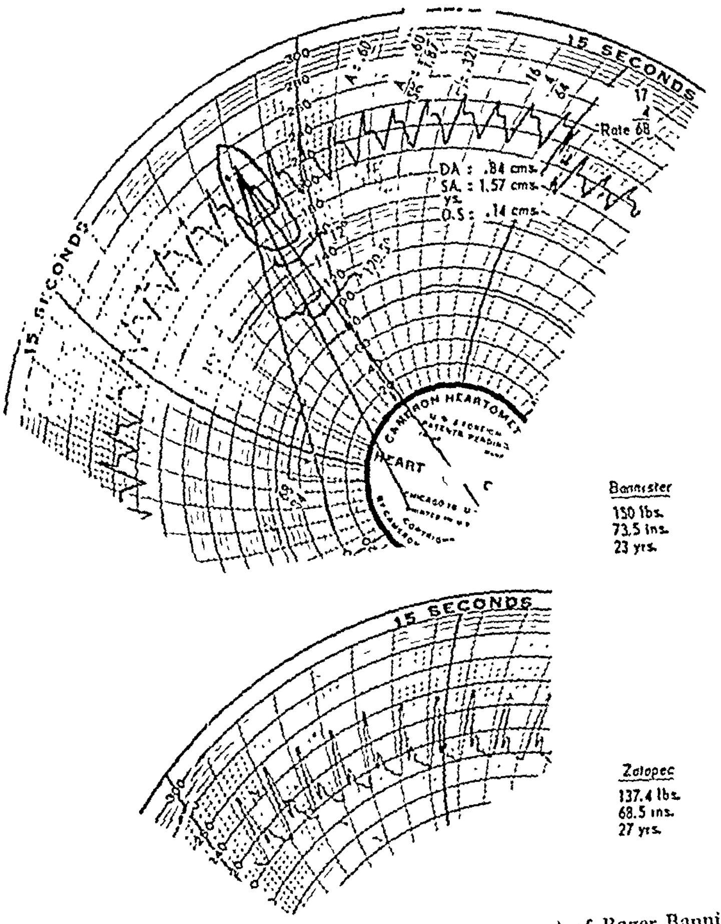

Fig. 1.—Basal sphygmograms (brachial pulse waves) of Roger Bannister and Emil Zatopec.

Bannister's heart in diastole is large and strong, like that of a racing greyhound (fig. 2). The transverse diameter was found to be 15.4 cm. and the frontal area 168.4 sq. cm. The internal chamber volume was calculated by the Keys and Friedell equation to be 1,068 cc., which, divided by body weight in kilograms, gave 15.65, the largest ratio found in our examination of several hundred normal subjects. The ratio of right to left diameters is 1:2.27, or just normal. Similarly to the Nylin ratio of volume to stroke volume (11.82), we used an inverted ratio: output in square centimeters (by brachial sphygmogram) to heart size in square centimeters (taken as the area of the heart in the diastolic phase on frontal x-ray). This index has a correlation of 0.68 with the gross oxygen intake (liters per kilogram of body weight) and with the time of the "all-out" treadmill run. Bannister had a result of 1.911, in spite of his large heart size.

Under conditions of hard work, Bannister's average oxygen intake was 3.226 liters per minute in our "one-bag oxygen-intake test," which is a high value for the 40-per-minute 17-in. chair-step test, with a respiratory quotient of 0.93. The distress that he built up during this effort was an oxygen debt of 0.0097 liters per minute per kilogram of body weight, or 3.473 liters of oxygen deficiency, which is very low. His pulse rate in the 15-second interval immediately after the test was, as stated, 120 beats per minute. In this all-out step test, his breathing was full and regular throughout. There were no signs of extreme distress, no extreme tensing, no facial grimaces, and no rapid

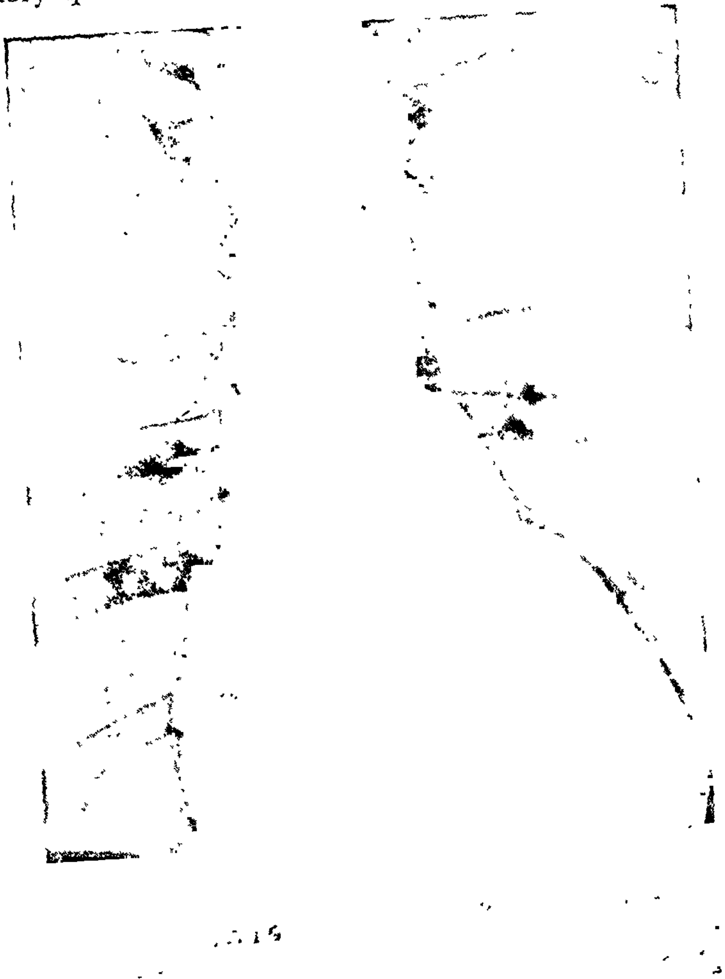

Fig. 2.—X-ray of Roger Bannister's heart in diastolic phase taken in May, 1952.

shallow breathing. The figures show that Bannister's oxygen deficit (debt) was very low. This was positive evidence of excellent adjustment to a very hard rate of work. The low pulse rate of 120 beats is a record among our observations, and his postexercise blood pressure of 170/60 mm. Hg was relatively low. It is significant that his diastolic blood pressure dropped during the work from 78 lying to 60 sitting and his standing from 86 to 60. We believe this drop in phase 4 of the diastolic pressure is related to cardiovascular adjustment to continuous and rapid work. Lack of adjustment is shown by a rise in diastolic pressure.

Bannister's best performance up to May, 1952, in the 1,500-m. run was 3 minutes, 48.4 seconds, and in the mile, 4 minutes, 7.8 seconds. In the July, 1952, Olympic Games at Helsinki, he ran the 1,500-m. run in 3 minutes, 47 seconds. He was remarkably good at stepping up and down on a chair at 30 or at 40 steps per minute. His gross oxygen intake per minute per kilogram of body weight of 0.0517 liters is the highest we have obtained of some 100 runners and athletes who have taken our 40 steps per minute all-out step test, in this he lasted 5¼ minutes. The highest precordial T wave in an electrocardiogram taken at rest was 25.3 mm. high, which was in keeping with his heart size of

25.1% larger than normal according to the Ungerleider-Clark and Gubner tables. After his all-out step test his quickness of recovery was amazing, since he had a postexercise pulse rate of 108. Beyond any doubt, these wonderful circulatory measurements explain his ability to hold the pace of 57.5, 60.7, 62.3, and 58.9 seconds per lap in his mile run at Oxford on May 6, 1953, or of 59.2, 59.8, 59.6, 60.2 seconds at Vancouver, Canada, on Aug. 7, 1953.

In a lecture in London, on May 5, 1952, I predicted that Roger Bannister had the potential to run a mile under four minutes, but his legs needed further seasoning and his schedule of three workouts per week was inadequate. I recommended some leg-training exercises and in a long talk told him that I thought he could do it. The London *Daily Mirror* published my prediction. A year later, the day after Bannister did it, the prediction was republished by the same paper. In New York, on the day after the run, he said that his new record was partially due to taking up an improved and intensified training program. When we tested him we were amazed that he could do only 15 straddle-chins, 14 floor push-ups, 38 squat jumps, 75 side leg-raisings (right and left), and 35 sitting tucks and at his poor flexibility. He was a good jumper and excelled on the agility run. In the 18-item all-round motor test, he was poor, scoring only 7 out of 18, missing all three of the balance tests, two of the flexibil' ts, the breath-holding test, and all of the mus- durance tests. It was plain to me that Bannis- was a great running type, rangy and lean, with powerful lungs and a crural ratio of 1.423, as high as our tables record. His long legs and trunk length class him as the running type. His running coordinations and breathing were beautifully developed. His feet are of the springy, running-jumping type (fig. 3) with good arches, almost no pronation and a long forefoot (ratio of left foot, malleolus length/total length = 0.555; right foot, 0.564).

Bannister has certain important psychological characteristics worth mentioning. On Cattell's 16-factor personality test, he was extremely high in the E and Q-2 factors, indicating extreme dominance rather than submission and extreme independence of spirit. His very high amplitude precordial T wave (25.3 mm.) and high systolic amplitude of the brachial pulse wave (1.57 cm.) suggest that he is also high in factor F (animation versus despondency). In Cattell's test his percentile rank was 80. His basal metabolic rate was +21.4%, or 44.9 calories per hour per square meter of skin. His own interpretation to us was that it was a matter of will to run the mile in under four minutes, but one day, when he felt like giving his all, he would do it. In more technical aspects, Bannister demonstrates the great importance of training by breathing oxygen mixtures and practicing regulation of breathing.

Role of Athletic Training

The role of athletic training for physical fitness is further typified by the case of the great Japanese swimmer, Furahashi. In 1949, he set magnificent world records in the 400-m. swim (4 minutes, 32.6 seconds) and 1,500-m. swim (18 minutes, 19 seconds) at Los Angeles. He was in magnificent physical condition. He was then a college student and free in the summer to train hard for from three to six hours per day. Between that time and 1952, he had been graduated and had settled down to an eight-hour working day. When he did so poorly at Helsinki, being shut out of the 1,500-m. swim and finishing last (4 minutes, 42.1 seconds) in the finals, we asked him the reason for his decline. His simple answer was, "No time to train hard anymore." It is believed that athletic endurance is developed mainly by training day by day. Whereas Zatopec did not race hard until he was 19 years of age, Roger Bannister before he was 12 years of age began cross-country running and competition in track. From 1941 to 1952 he trained regularly in sports, including some rowing and Rugby football during 1944-1946. From 1946 on he specialized in track but did cross-country running during the winter to build endurance.

Predictions of All-Round Athletic Success

Several methods have been used to predict relative success in college athletics. DiGiovanna studied 18 measures in relationship to eight sports and concluded that the athletes in general were differentiated from normal young men by having more explosive power, by being larger and heavier, and by having greater arm and leg strength. Each sport was shown to have its own unique pattern of factors for success, but, in general, athletes are typically stronger and heavier and are more powerful (by strength multiplied by vertical jump) than nonathletes of the same height. While DiGiovanna's study in 1943 showed statistical significance for most of the various measurements, no composite formula was developed beyond the use of MacCurdy's power formula of strength multiplied by velocity, simulating the physics equation of power = force × velocity, developed in 1933. This was based upon the combination of two lines of research previously published by Rogers in 1925 and Bovard and Cozens in 1928. In 1887 Dudley A. Sargent had published significant articles on "The Physical Characteristics of the Athlete" and, in 1921, "The Physical Test of a Man." Sargent's work was empirical rather than based upon modern statistics of prediction, but his insight was remarkable. He was a leading advocate of the pulley-weight exercises and of dynamometer strength tests. Several workers have shown the basic importance of strength to athletic performance. Several others have emphasized speed.

The next important advance came in 1940 with the work of Leonard A. Larson, who made a careful statistical analysis of the data of 15 motor tests selected on the basis of their presumed relationship to all-round athletic ability. Larson demonstrated that "dynamic" events, in which a man lifted, pushed, pulled, or propelled his total body weight against gravity, had much more relative validity than the older static tests of dynamometric strength, which in themselves were more valid than any combination of body measurements or proportions. Larson produced a simplified weighted formula: predicted athletic capacity = 2.12 (no. of chins) + 2.27 (vertical jump) + 1 (no. of dips on parallel bars) (in standard scores). Larson further adjusted his prediction tests in 1941 to add the dodge run (outdoors). He also continued to study various combinations and recommended simplified tests to the U. S. Army Air Force composed of (1) baseball throw for distance, pull-ups, and vertical jump and (2) 300-yd. shuttle run, pull-ups, and sit-ups. In using these tests with 1,031 college freshmen, Landis showed that a course in basic conditioning produced the greatest improvements in a semester of training, with tumbling-gymnastics next, compared to swimming, tennis, boxing, weight-training, volleyball, and wrestling.

In an analysis of the Larson-type tests, we found certain omissions that made us dissatisfied with the tests. One of these was the omission of any item that took longer than two minutes to perform. A comprehensive monograph entitled "Endurance of Young Men," published in 1945, sustained our position that the mile run had greatest all-round predictive value in a 28-item athletic criterion. Next came chinning the bar, floor push-ups, hops, dips on parallel bars, forearm push-ups, sitting tucks, and side leg-raisings. Some items rated surprisingly low, including the elbow-to-knee sit-ups, the step test, the stick body, leg lifts, sit-ups (feet free), chest-raisings and V-sit test. Our factor analysis and test construction work yielded several test batteries, which have been published. The University of Illinois has since used the three-item all-round muscular endurance test (0.366 chinning the bar + 0.401 sitting tuck + 0.411 mile run). Our laboratory has used the four-item indoor test (0.323 chinning + 0.279 floor push-up + 0.282 sitting tuck + 0.365 hop). In these equations standard-score results are multiplied by the weightings, the results added, and the totals rated by our published tables. Track sprinting aptitude is shown by the total-body-reaction-time test published in 1951 by Garrett and me. It is fairly highly correlated with the vertical jump and the Illinois agility run test. High-jumping ability is fairly predictable from the vertical jump test, with height and length of legs related to length of trunk.

I made a comprehensive study of the relationship of various physical fitness tests to the total of a 22-item criterion in 1947. The highest (most valid) type test was the 18-item stunt type test or the 14-item motor test; next was strength (sum of two grips, back-lift, and leg-lift on dynamometers); next was somatotype rating; and next the Harvard five-minute step test. The 18-item motor test has been widely publicized. In addition to those mentioned, a few other desirable but less valid tests are the Schneider index, vital capacity, adipose tissue, and a body-type picture with posture measurements. The 14-item test revealed an appalling amount of unfitness among the young men coming to college from the high schools. The 18-item test has shown even greater proportions of unfitness among the adult population, both men and women. An interesting observation is the fact that a great runner like Roger Bannister could be so poor in sections of this test involving balance, flexibility, strength, breath-holding, and even aspects of muscular endurance. No single sport develops all the types of fitness sampled even by this test. The case for all-round fitness has been presented by a competent committee at Springfield College, Springfield, Mass., and also by a competent committee composed of the entire staff at the University of Illinois.

Superior short-duration athletic performance involves power as stated. Several studies have separated power into strength and velocity (speed) components. The first notable study of this type was by Charles H. McCloy of Iowa University, in 1932. Other studies have followed by Rarick, in 1937; Hutto, in 1938; Coleman, in 1940; and Carpenter, in 1941. McCloy in 1940 in *Psychometrika* summed up this particular line of research, particularly with respect to the use of the factor analysis method.

Body Build and Athletic Performance

A broad view of physical fitness includes the structural aptitude (body build) for the particular event. Being "fit for the event" involves, first of all, a physique appropriate to the event. Thus, the high jumper is usually tall and slender, relatively long in the forelegs to thighs area, and with a long metatarsal arch compared to the length of the whole foot; he is built somewhat like a grasshopper, with long forelegs and feet along with strong thighs and light body (as are DeSilva, 1952 hop, step, and jump Olympic champion, and Jesse Owens, 1936 Olympic sprint and broad-jump champion). The typical diver is medial and muscular in build (as are Clotworthy, Browning, and Harlan). The middle-distance runner is generally long-legged, with a relatively lighter upper body (as are Sowell, Wint, Bannister, Landy, and Tabori). The typical soccer or football athlete is muscular and may be tall, medium, or short. The weight lifter is usually seen as a heavy (muscular and fat) type with unusually short levers (as are Anderson, Davis, and Kono).

Endomorphic persons are notably absent in any distribution of athletes. These are types with long and bulky viscera, large amounts of fat and fewer muscle fibers than are needed for athletic success. Some mesomorphic wrestlers grow fat, but they are not truely endomorphic. Kohlrausch, Arnold, Telkka, Bartolome, Sills, and I have made various studies of athletes, utilizing anthropometric techniques. Sills and I have made adaptations of Sheldon's somatotyping method, which has also worked out well in the classification of aviators. There is extensive literature on the relationship of body build to athletic performance, which is summarized by the authors mentioned. An appropriate body type helps to win, but there are important exceptions to the rule, due to many years of developing skill, experienced judgment, and the will to win. There are some short tennis players, swimmers, and ball players as exceptions, just as there are some heavy golfers, pistol shooters, and sprinters, or short pole vaulters and basketball players, but we consider these to be the exception rather than the rule.

In making a prolonged study of Bob Richards, we found that he could run as fast with the pole as anyone and could spring exceptionally well onto the pole at the moment of take off, but his timing and speed of draw up were poor. Dick Ganslen coached him carefully on this point, and I advised a weight-training program for his hands, shoulders, and thigh taken one minute after this was 6.82; the 100-yd. drop-off (without a dive and all-out all the way) swimming endurance index was 1.5 seconds, and his ratio of heart output to heart size was at the top of the scale. We predicted his 100-yd. drop-off swim to be 55.6 seconds, and he swam 54.9 seconds with a 1.9-second drop-off. This test combines short-sprint speed for 60 ft. with endurance by the formula published by me in 1935: time for 100 yd. in seconds = 5.98 (time of 60 ft. sprint in seconds) + 2.88 (drop-off index) -2.63.

Other equations for the diagnostic analysis of swimming were published by Wilson and me, for predicting the short 60-ft. sprint (crawl and back and breast strokes). I also published the prediction equations combining the most valid factors for predicting success in 100-yd. and 440-yd. swims. This type of work significantly differentiates power and skill from endurance. Swimming for speed is shown to be mainly power and skill for 60 to 75 ft., but as the distance lengthens the circulatory-respiratory fitness looms as the dominating factor. Ford Konno and Yoshinobu Oyakawa, the great Hawaiian Olympic champions, have very flexible ankles, strong arms, and wonderful kicks, but their ability to hold such a fast pace over the longer distances is mainly due to relatively great circulatory-respiratory fitness and to their training diligently to hold the fast pace over a longer and longer distance. From our comparative studies of the Japanese and American swimming teams of 1932 and 1936, we demonstrated that the percentage of superiority of these Olympic men was mainly in circulatory-respiratory fitness, compared to groups of Yale University, Dartmouth College, and Springfield College groups. These data were published in 1932 and 1947.

The gross-oxygen-intake test is the most valid test of the ability of the heart, lungs, and muscles to circulate the blood. It has been applied most successfully to treadmill upgrade running, ordinary flat running, rowing, running in place, and swimming, but it has not as yet been related to other types of performances. It would be valuable to know the gross oxygen intake results on a variety of hard exercises. From available data in hand now, it seems clear that the test is most valuable as a predictor of performance in events of endurance that use a great deal of musculature and are continued to the point of virtual exhaustion.

Specificity of Physical Fitness Tests

The fact that fitness has many specifics, like a mosaic, has been hard to comprehend. It is clear that no single item measures all aspects of fitness. The truth is that no two, three, or four items, even when combined in an optimum manner, measure all aspects of fitness. The proof of this is reflected in the following research: 1. The Larson chinning–vertical jump–bar dipping test was correlated with my 30-item motor fitness criterion. The result was a correlation of +0.447 in 171 cases of young men in the service classes at the University of Illinois. The Larson weighted index correlated +0.338 with endurance, +0.383 with power, +0.492 with agility, +0.218 with dynamometer strength, +0.031 with flexibility, and +0.019 with balance. No prediction of body-type or circulatory-respiratory fitness from this Larson test was possible. 2. Any table of intercorrelations for measures of balance, flexibility, agility, strength, power, and endurance was shown to have a predominance of low correlations between the items. From the 30-item motor fitness criterion Welser, Huffman, and I made a simplified 7-item motor fitness test that included items of greatest all-round predictive value ($R=0.78$). The items included were dive and roll, medicine ball put, bar vault, chinning, leg-lifts and sit-ups, breath-holding, and man lift. 3. A factor analysis of 22 items of fitness gave six basic components: constitutional body type, thinness of adipose tissue, metabolic rate, pulse rate condition, strength, and coordination in gymnastic and tumbling stunts (14 or 18-item motor tests).

Cardiovascular Components

From available evidence there seem to be at least five types of cardiovascular condition, each of which may be called a component. First, the autonomic nervous balance (component 1) is determined by blood pressure, pulse rate, and pulse wave tests in the quiet state, from palmar skin resistance or conductivity, or by noting the rise in pulse rate after injection of atropine (vagus tone). Second, splanchnic tone (component 2) is the distribution of blood against gravity as noted in the change in pulse wave, pulse pressure, or pulse rate in changing from lying to standing or from sitting to standing positions. After a subject stands for a minute, any tendency of the blood to settle into the feet, legs, or splanchnic region will result in a smaller pulse wave, reduced pulse pressure, or a rise in pulse rate.

Third, efficiency in long submaximal work (component 3) is the ability to work economically at a submaximal pace for a long time as indicated by pulse rate, blood pressure, pulse waves, and oxygen-intake tests. A rise in pulse rate, blood pressure, and oxygen consumption indicates reduced efficiency, as does also a reduced pulse wave. Fourth, efficiency in athletic (racing) endurance (component 4) is the ability to work relatively long at a pace that will develop an oxygen debt of 3 or more liters (maximal exercise) or to work a long time at a set pace on the treadmill or in the step test. The higher the oxygen consumption, the better. An oxygen debt above 3 liters is proof of entering a semiexhausted state but is not reliable.

Fifth, recuperation after exercise (component 5) is the recuperation of pulse rate after relatively hard exercise as in the five-minute step test. Various tests have emphasized measuring the postexercise pulse rate, blood pressure and blood lactate levels, pulse waves, and blood pH concentrations. Exercise of a severe type produces changes in these, but, so far, evidence that the all-out performances can be predicted from such data is unsatisfactory. Lucien Brouha assumed that this was so, but in a series of studies I demonstrated very low correlations as reported in a 1945 National Research Council study on "Endurance of Young Men." Craig Taylor had even earlier, in 1943, severely criticized use of the blood lactate test in a report to the National Research Council. The lack of validity of this test was explained in work by

Sacks and Sacks and Shaw, in which they pointed out that in human subjects the amount of blood lactate from venous samples taken after exercise does not indicate the total amount of lactate in the body. Some lactate spills over into the urine.

I summarized these objections to the blood lactate test in 1951 in "Physical Fitness of Champion Athletes." In addition, Montoye used the data from the Harvard fatigue laboratory in 1953 to restudy the relationship of the "recovery index" and blood lactate level (taken five minutes after exercise) and showed a correlation between them of −0.470, between lactate level and maximum pulse rate of +0.131, and between recovery index and maximum pulse rate of −0.637. After 12 weeks of training, the coefficients were −0.722, −0.782, and +0.665 respectively.

Montoye found the Harvard (Brouha) step test to be of limited value, because correlations with a wide variety of strenuous work criteria are in general very low. They were half-mile run time, −0.232; ergocycle time, 0.091; maximum number of sit-ups, 0.286; cross-country running speed, 0.38; mile run without training, 0.31, and after training, 0.54; 300-yard run time, −0.272; treadmill run time, 0.4; order of finish in the Boston Athletic Association cross-country 'marathon, 0.32. It is agreed by several workers that the pulse rate after exercise is sensitive to training. Training results in a lowered maximum pulse rate and lowered blood lactate levels during a standard exercise, but Taylor's correlations of these with all-out run time are too low (−0.56 and −0.44 respectively) to be of much value in predicting individual performance.

Athletic training affects all of these components, but very specifically. We found that in six weeks of training a young male subject improved at 7 miles per hour but not at 10 miles per hour, when he ran three miles per day at 6 to 7 miles per hour. Many top athletes in component 4 have been shown to be ordinary or poor in certain of the other components. It has been reported several times that all-out running times could not be predicted from components 1, 2, 3, or 4. Great confusion can be eliminated by calling these cardiovascular components what they are and using tests of component 4 to predict athletic endurance.

Skill, Coordination, and Fitness

As greater and greater skill develops as a result of continual practice, the experienced athlete is able to accomplish a given stunt or race with relatively less effort. It was surprising to find that experienced athletes do not develop any higher oxygen debt (internal oxygen deficit) than nonathletes. My 1948 study shows that 18 normal (untrained) young men averaged 7.37 liters of net oxygen debt compared to 7.23 liters for 20 experienced varsity athletes. However, the athletes had greater gross oxygen intake (6.89 liters) compared to the nonathletes (4.06 liters), an advantage of 22 in standard scores, or an advantage of 71.2%. The athletes develop the oxygen deficiency at a faster rate (0.062 liters per minute per kilogram of body weight) compared to the nonathletes (0.047 liters per minute per kilogram of body weight). Most of all, the athlete has a greater aerobic capacity and does no more of his work on anaerobic capacity than the untrained man. This explodes the value of the oxygen-debt test as a test from which endurance performance can be predicted.

When A. V. Hill figured the oxygen requirement as net oxygen intake plus net oxygen debt divided by time of effort, he was interested mainly in accounting for the oxygen cost attributed to the exercise, and, from this point of view, he is absolutely correct. From the point of view of which test is best to predict the time of the endurance effort, the gross oxygen intake (liters per kilogram of body weight) gives a validity correlation of +0.87 compared to +0.57 for Hill's oxygen requirement, while the correlation of net oxygen debt (in liters) is +0.19, practically worthless. Why then should this part be used at all? If we use the rate of oxygen debt, we introduce the time of the effort in the denominator, which, of course, correlates negatively with the time of the run as the criterion, and thus the correlation is −0.60 but is spurious.

The trained athlete is usually more skillful and, hence, more economical. He breathes better, saves himself whenever possible, and avoids tenseness in any muscle group that would hinder circulation. With experience he learns to relax as much as possible. He uses muscle effort exactly where it is needed and then relaxes to let the blood flow and deep breathing to occur. Frequently, such skill is merely attributed to experience. To observe Herb McKenley finish a 400-m. run—or Rhoden or Kelly—is to witness such controlled relaxation in action. In the Helsinki games, Dick Cleveland was apprehensive and he tightened up, ruining his chances in the 100-m. swim sprint; whereas, Clark Scholes, a cooler and more experienced swimmer, relaxed a bit more and had better circulation with which to win. Cleveland made his world's record before a small crowd and against less formidable competition in his homeland.

It is not the purpose of this paper to cover mechanics of athletic performance, but scientific analysis of many events has yielded formulas for analyzing events such as a swim, sprint run, shot put, discus throw, javelin throw, pole vault, high jump, and broad jump. The physical economy is represented in such formulas. Performances follow, first of all, physical laws; then physiological adaptations and psychological adjustments further modify the effort. No physical performance is a simple matter. Reference to studies in mechanical analysis can be found in Webster's "The Science of Athletics," Bunn's "The Scientific Principles of Coaching," or in the research methods book of the American Association for Health, Physical Education, and Recreation.

The usual scheme of analysis is (1) to analyze the mechanics of the event; (2) to analyze the physical body build and aptitude of the performer; (3) to analyze the physiological fitness of the performer; (4) to analyze the psychological attitudes of the performer; (5) to get some physician to help remedy all health hazards, chronic ailments, or infections; (6) to prescribe developmental and conditioning activities for detectable weaknesses; (7) to plan a program of training to bring the performer to a peak at the needed moment; (8) to check the dietary regimen carefully and suggest possible improvements; (9) to seek ways of observing and studying the most competent performers; and (10) to arrange a progressive schedule of competitions to season the competitor, realizing that this takes time.

Age, Performance, and Fitness

The evidence presented by Ernst Jokl indicates that lifelong physical training exerts a powerful influence on inhibition of the usual decline in physical ability, athletic efficiency, and health, but evidence that the immunologic resources of the body are affected is not available as yet, nor is it claimed with respect to the more virulent infectious diseases. Jokl's data on 1,609 men, aged 40 to 84 years, and 98 women, aged 32 to 52, was taken in 1952 at the National Gymnastic Festival for the Old in Marburg, Germany. The absence of degenerative diseases of the cardiovascular system, of neoplastic growths, and of kidney ailments among the older participants lead Jokl to the conclusion that the lifelong practice of gymnastics and other athletic sports had maintained their health and fitness in a remarkable way.

Over the past 50 years, in Europe and in the United States, there has been a general lengthening of the period of optimal usefulness of men and women. Today the trend is for people to mature younger—estimates indicate that the menarche in girls occurs five years earlier than in 1875—and they live longer. It is believed that this trend is accentuated by sports and regular physical training.

Diem studied the performance in the last three Olympiads to show that more and more the participants are both younger and older, with many in their teens and many over 40 years of age. Among the medal winners at the 1932 Olympic Games in Los Angeles were two 14-year-old Japanese schoolboys in the 1,500-m. swimming race, Kusso Kitamura and Shozo Makino, of Japan, who finished a length ahead of every other contestant. Among the medal winners at the 1948 games in London were the 16-year-old Japanese discus thrower, Ko Nakamura, the 18-year-old gymnast, Anita Barwirth, and the 17-year-old decathlon champion, Bob Mathias. While Jokl and Diem cite many others, old and young, in a similar relationship, our own data show that the former Olympic decathlon champion and world's high jump record-holder in 1924, Harold Osborn, at 51 years of age, has taken extraordinary physical fitness tests as shown by our laboratory tests in 1951 and 1952. In Finland, in 1952, it was impressive to see Paavo Nurmi still running well at 50 years of age and Hannes Kohlemainen run up the steps of the campanile (tower) at the stadium at 68 with an amazing demonstration of fitness. We found René Cochet, the great tennis star, fit and playing in the national tournaments at age 50. Jokl has estimated this advantage in tennis, as preventive of physiological aging, to be 6 to 10 years.

In our data on the all-out step test at 36 to 40 steps per minute, there is a surprisingly poor relationship of age to stepping time or to gross oxygen intake among 55 former athletic champions ($r = -0.566$). There is a slight trend for the younger subjects to develop a somewhat higher oxygen debt ($r = -0.364$). The total net oxygen cost was positively related to performance time ($r = +0.547$), but the rate of net intake oxygen was poorly related ($r = -0.341$ for liters per minute and -0.179 for liters per minute per kilogram of body weight). Several older men, who had maintained regular endurance training, still had relatively high gross-oxygen-intake capacity and were able to prevent any rise in the diastolic (phase 4) blood pressure. A few could still produce a drop, characteristic of a youthful competitor with a cardiovascular system still capable of making a good adjustment to hard endurance work. For instance, Harold Whitlock, many times walking champion, at 48½ years of age, with a starting blood pressure of 140/80 mm. Hg had 186/74 after stepping all-out for 2.17 minutes at 40 steps per minute on the 17-in. bench.

In the past few years we have accumulated evidence that favorable adjustment of the cardiovascular system, usually with marked reduction of peripheral resistance, accompanies systematic and progressive physical training of the endurance type. An example of this is shown in the table. We are led to believe that either physical training has been misunderstood or it has never been understood regarding this type of beneficial effect upon the cardiovascular system. By the use of Kellogg's tables of blood pressure related to expected loss of life, we have consistently shown the reduction of systolic and diastolic blood pressures, the increased stroke volume, larger pulse waves, and improved endurance in all-out treadmill running that *accompany such training of six months to a year.*

Change in Peripheral Resistance Associated with Physical Conditioning

An illustration is given of changing peripheral resistance in a 47-year-old subject as a result of five months of physical conditioning in 1953. The method used is simply that of substituting the pretraining figures of mean blood pressure (P_m), stroke volume (V_s), rate of heart beat (R) per second and solving for total peripheral resistance (TPR).

Pretraining:

$$\mathrm{TRP} = \frac{P_m}{V_s \times R} = \frac{155}{29 \times 0.800} = 6.69 \text{ mm. Hg per cubic centimeter per second}$$

$$P_m = \frac{180+130}{2} = 155 \text{ mm. Hg} \qquad V_s = 29 \text{ cc./stroke} \qquad R = 48/60 = 0.800 \text{ second}$$

Post-training:

$$\mathrm{TPR} = \frac{P_m}{V_s \times R} = \frac{128}{75 \times 0.867} = 1.97 \text{ mm. Hg per cubic centimeter per second}$$

$$P_m = \frac{158+98}{2} = 128 \text{ mm. Hg} \qquad V_s = 75 \text{ cc./stroke} \qquad R = 52/60 = 0.867$$

Ratio of pretraining to post-training total peripheral resistance, $6.69/1.97 = 3.40$ or 3.40 to 1.

(This equation is essentially that given by Wiggers in his book "Cardiac Dynamics." Henry has also made use of the same type of equation in a recent article and accredits the earlier work of Wezler and Böger.)

The subject was given five months of conditioning work, which consisted of a 30-minute period of conditioning exercises on the deck of a swimming pool, followed by a shower and a 20 to 25 minute swim in a regular swimming pool, 76-78 F in temperature. The exercises were led by an instructor five days per week. Once each week the exercises were of the "test-exercise" type in which each exercise was done for as long as the subject could maintain it by voluntary effort.

By another calculation the volume elasticity was reduced from 3.45 to 1.60, a reduction of 53.6%. (The volume elasticity [E] equation is $P_s = V_s\ [TPR \times R + E/4]$ wherein, P_s=systolic pressure in mm. Hg and all other notation is the same as in previous equation.) Thus, we might say that the suppleness (give) of the large blood vessels above the heart was increased. It is not fully known how much of the effect is due to dilatation of the arterioles and possibly the capillary beds, but it would seem theoretically that both aspects had occurred.

* Data from McAdam and Cureton unpublished data. The equation used for peripheral resistance is essentially the same as given by Wiggers in "Cardiac Dynamics." Henry uses the same but quotes the early work of Wezler and Boger. P_m = mean blood pressure sitting (or the average of lying and standing), including the sum of systolic and diastolic pressures divided by 2; V_s = stroke volume by Grollman method with correction by Keys method, R = heart rate per second, and TPR = total peripheral resistance = $P_m/V_s \times R$.

† Used Keys' correction for absorption coefficient

‡ Used Keys' corrections for hyperventilation

In comparison with the comparable normal adult sample of men measured on the same 128 tests, 55 former champions, averaging 44.39 years of age, 69.37 in. (176.2 cm.) in height, and 165.29 lb. (76 kg.) in weight, were more mesomorphic, more linear in skeletal build and had less fat. The former champions also had slightly wider shoulders, smaller hips, and smaller gluteal and abdominal girths, they also had better feet, were found to have stronger dynamometer strengths, and scored better results in cardiovascular tests (better Barach, Schneider, and five-minute step test scores, better results in brachial sphygmograms, and higher T waves in precordial leads 4 and 5). The average weight residual of 17.05 lb. (8 kg.) was greater than that of the comparable sample of adults and even greater than the result for normal young men, indicating greater tissue density because these former champions were stronger and had less fat. Our external fat index correlates +0.70 with Benke's hydrostatic weighing determination of total fat.

The lying and standing blood pressures were just average by the tables for general adults, but the pulse rates were considerably lower. There was no indication that the former champions show relatively greater strain or deterioration, but they instead had significantly stronger circulation, greater vagus tone, and larger precordial deflections in the electrocardiogram. In the ratio of the area of the brachial pulse wave to the frontal area of the heart in diastolic phase (according to x-ray), the former champions showed greater proportionate stroke output per unit of heart size (3.489, compared to 2.599 for the comparable adult sample and 3.442 for young men). Their transverse heart diameters averaged 13.35 cm. (+4.73%), compared to 14.12 cm. for the comparable sample of adults and 13.1 cm. for normal young men (+0.60%). Comparison of the groups on an all-out step test for time and gross oxygen intake in the hard exercise showed the former champions to be superior to the comparable sample of the middle-aged, but both of these older groups were poorer in step-test time than the sample of young men. In gross oxygen intake the former champions were better than both other groups.

The former champions had a strength per pound of body weight of 7.09 compared to 6.54 and 5.87 for the other two groups respectively. The vertical jump reaction times were 0.271 seconds (visual), 0.254 (auditory), and 0.245 (combined). being about 5 in standard scores above the adult average, as were also the results for the agility run and vertical jump. However, both adult groups were considerably poorer in all-out chinning and dipping endurance exercise than the young men, but here again the former athletes had deteriorated less than the comparable sample of men. A division of the former champions into three subgroups designated "in continued training," "moderately active," and "sedentary" showed statistically significant differences in favor of the group in training over the other two groups in practically all physical fitness test items.

Untreated Factors

No attempt has been made to cover all that could be said about psychological factors or sex or racial differences. I am conscious of this omission, but these factors must be treated in subsequent articles. Most of all, each event has its own special mechanics, psychological mind-set (motivation), weather conditions, and timing. No single event has been adequately covered, nor has the long-range effect of each sport.

Because of space limitations, a bibliography has been omitted from THE JOURNAL and will appear in the author's reprints.

FOREIGN LETTERS

BRAZIL

New Method of Closure of Abdominal Wall.—Dr. A. J. Silveira and co-workers reported in *Revista paulista de medicina* (49:54, 1956) a new method of closure of the abdominal wall, which they have used in 101 operations with good results concerning suppuration and dehiscence. The suture of the fascia is made with a removable nickel-chromium thread, which they were the first to use. The suture of the fascia is made in zigzag, and the thread is put under tension, externally, by means of a metallic extending bar devised by Dr. Silveira. Metallic threads were preferred because sutures of vegetable or animal origin have crevices and gaps in their structure that favor the proliferation of germs, while the metallic threads are uniformly compact. For hemostasis the authors relied on vascular torsion, keeping all bleeders clamped during the operation, and the use of a U-shaped stitch that is removable through the skin. The extending bar and the metallic threads are removed eight days after the operation. Two of the patients in this series had to be operated on sometime after the first operation, at which time a firm aponeurotic scar was found. There were no eventrations in this series, and suppuration developed in only two patients, both of whom had had a cesarean section. In both of them, the poor preoperative condition of the patient could explain the occurrence of suppuration.

Arteriovenous Malformations.—Dr. M. P. Albernaz presented to the Associação paulista de medicina three cases of arteriovenous malformations in the region of the vertebral artery. Cerebral arteriography now permits the neurosurgeon to recognize arteriovenous malformations, which formerly were seen only at autopsy. The first patient had an arteriovenous malformation of the right posterior cerebral artery, and the second had an intrabulbar lesion. In both these patients the blood supply was maintained entirely by the vertebral system. The third patient had a great malformation of the region of the third ventricle, receiving blood from the right and left carotid systems but mainly from the basilar trunk. The first patient refused operation, the second died during the extirpation of the lesion, and in the third the lesion was considered inoperable. In this last patient the fractional pneumoencephalography was of great help in localizing the lesion.

Blastomycotic Tumor of the Femur.—Maffei and Hungria reported, in *Arquivos dos Hospitals da Santa Casa de São Paulo* (2:52, 1956), their findings in a patient with blastomycosis. One unusual finding was the presence of a solitary osseous lesion in the neck of the femur with no symptoms referable to it. Another was the presence of an osseous abscess that was sterile in the common culture mediums. The radiologist described the lesion as localized, destructive, and extra-articular without periosteal reaction or surrounding decalcification. Metastatic carcinoma, syphilitic gumma, osteoarticular tuberculosis, sarcoidosis (Boeck's sarcoid), osseous cyst, giant-cell tumor, plasma-cell (multiple) myeloma, Ewing's sarcoma, and chronic localized osteomyelitis had to be ruled out. The diagnosis was finally made by demonstrating the parasite by direct microscopic examination of the pus and in a biopsy specimen. Blastomycosis may give rise to a localized (hypergic) or a disseminated (anergic) reaction. The former is an inflammatory process with a granulomatous reaction due to the maximal fixation of antigen by antibody; the latter is a nonspecific necrosis with little or no cellular reaction. The treatment depends on the type of reaction. Sulfonamides are valueless and carry the danger of leukopenia and agranulocytosis, which occurred in the case reported. In localized lesions such as were seen in the authors' patient, complete excision is indicated. The patient was operated on and recovered completely.

Effects of Hysterectomy on Ovarian Function.—Dr. J. Gomes da Silveira and co-workers reported in *Revista de ginecologia e d'obstetricia* (98:515, 1956) that certain changes of vaginal cytology and ovarian structure followed hysterectomy in a group of adult rats. An identical study was made on women in whom vaginal smears were obtained before and after hysterectomy. The preoperative and postoperative rates of urinary elimination of gonadotropins, pregnandiol, and 17-ketosteroids were also compared. In some of these women subjected to a second operation but in whom the ovaries were intact, a biopsy specimen of these organs was taken. Several dogs were also subjected to hysterectomy and the ovaries examined from four to eight months after the operation. The authors' findings were as follows. 1. In adult rats hysterectomy did not cause immediate alterations in the curves of vaginal cytology that could be simply attributed to the absence of the endometrium, but it did determine late changes that corresponded to structural alterations of the ovaries, such as those found in the ovaries of women and dogs on whom hysterectomy had been performed. 2. In women hysterectomy brought about in general the symptoms of hyperfolliculinemia, corresponding to the great changes of the ovaries, but no significant modifications of the rate of urinary elimination of gonadotropins, pregnandiol, and 17-ketosteroids.

INDIA

Busulfan in the Treatment of Leukemia.—J. B. Chatterjea and co-workers (*Bulletin of the Calcutta School of Tropical Medicine*, July, 1956) used busulfan in the treatment of 11 patients with chronic granulocytic leukemia with encouraging results. Depending on the leukocyte count, the dose varied from 4 to 12 mg. daily and was gradually reduced to a maintenance dose of 2 mg. daily or on alternate days. In four patients it was the only drug used, and in two it was given during a relapse after initial treatment with deep x-ray and urethan. In the remaining five patients it was given in smaller dosage at a time when a relapse was imminent after deep x-ray treatment. In the first group, there was satisfactory hematological improvement, with regression of the size of the spleen and improvement in general condition. In the second group, the leukocyte count came down and the general condition improved. In the third group, the drug immediately controlled the proliferative disorder, and the blood findings and clinical condition reverted almost to normal. No toxic symptoms were noted. Busulfan appears to be the drug of choice in the treatment of chronic granulocytic leukemia.

Leprosy.—Fletcher and Shiralkar reported the results of treatment with Avlosulfon in 15 hospitalized patients with leprosy in *Leprosy in India* for April. The drug is given intramuscularly. Of the 15 patients, 12 had the lepromatous form, 2 had a borderline infection, and 1 had the tuberculoid form. All gave strongly

---

The items in these letters are contributed by regular correspondents in the various foreign countries.

positive skin reactions at the commencement of treatment except the patient with tuberculoid leprosy, whose reaction was only slightly positive. Initially the dose was 50 mg. a week, but it was gradually increased to 200 mg. a week. No side-reactions were observed, except for pain in a few patients. All the patients improved clinically except the one with tuberculoid leprosy. Bacteriologically, 3 became negative, 2 were doubtful, and in the remaining 10 the bacillary count was greatly reduced. There was no deterioration in the hemoglobin level in most of the patients. The results compared favorably with those obtained by others with the same drug. The reduction in the quantity of medicine used, the simplicity of its preparation, the effective control over the dose taken by the patients, the absence of complications, and sureness of action are the chief advantages of the use of this drug.

Gandhi Medical College.—The foundation stone of a Gandhi Medical College building was laid at Bhopal in September by the Home Minister, who said that the establishment of the medical college was a welcome step, as the number of such institutions in the country was inadequate. Even if the present number was increased twentyfold, there would still be a need for more colleges. He hoped that medical facilities would be brought within the reach of every citizen, but he cautioned against opening understaffed and ill-equipped institutions.

World Health Organization Regional Committee.—The regional committee of the World Health Organization for Southeast Asia held its ninth meeting in New Delhi in September. Nearly 200 health projects to be carried out by member governments in 1958 were approved. In addition to delegates from Afghanistan, Burma, Ceylon, India, Indonesia, Nepal, Portugal, Thailand, and the United Kingdom, representatives of the United Nations, International Labor Organization, Food and Agricultural Organization, UNESCO, UNICEF, and the U. N. Technical Assistance Board also attended the meeting. The projects approved by the committee relate to the control of communicable diseases, maternal and child health, environmental sanitation, and training of medical personnel. The committee also formulated recommendations for the development of school health programs and accepted in principle an integrated plan for the eradication of malaria in Southeast Asia by 1961.

IRELAND

Voluntary Health Insurance.—Recommendations have been made to the Minister of Health of Eire for a voluntary health insurance plan for the whole country. Unlike Britain, Eire has no national health service covering all income groups. Free or partly free treatment is available only to the lower-paid workers. An insurance plan to cover the cost of hospital and medical, surgical, and maternity specialist services, but not treatment by general practitioners, is considered possible. Drugs and medicines would also be included if a proportion of the cost were paid by the insured person. Examples of minimum benefit rates are as follows: up to $20 weekly for hospital or clinical maintenance for a maximum of 10 weeks; from $20 for minor operations to $70 for major ones, and from $3 to $9 for anesthetics. Benefits for other services and drugs are also given, with limits for any one year. The annual premium would be $11.20 for an adult and nearly $4 for a child. Increasing the adult premium to $13.30 would make possible a maternity benefit of $56. Tax relief could be claimed on the premiums. The plan will probably be administered by a nonprofit organization backed by the government. Voluntary health insurance exists in Eire, but only on a limited scale and not through the normal commercial insurance companies.

JAPAN

The Japanese Diet.—Although the government announced a large surplus of rice, it cut the quotas in certain categories. For example, whereas a man doing hard labor such as mining coal used to get 600 gm. per day, his allotment has been cut to 400 gm., the same as everybody else, and, whereas there was formerly a slight increase for teenagers and middle-aged persons, they too get 400 gm. a day under the new quota. Japan has to import 6,500,000 tons of rice annually, or more than 25% of her total requirement. Prior to World War II, importations from Korea and Formosa sufficed, but now most of her imported rice comes from the United States. The introduction of wheat flour in the form of noodles and bread to relieve the rice shortage is proceeding rapidly under government sponsorship, though not rapidly enough. Superstitious belief still persists that rice has dietary factors not found in any other grain. Unfortunately, the polished rice eaten in Japan is so deficient in dietary requirements that it is common to find children with pot belly, anemic pallor, and bow legs. Since the children are almost entirely breast fed, the mothers' inadequate diet is reflected in the children. Many people eat no meat. While more fresh milk is being consumed due to the expanding dairy industry, no uniform standard prevails and the fat content of the milk varies widely. A strict government inspection of milk supplies appears to be still some distance away.

Nagasaki and the Atom Bomb.—On Aug. 9, the city of Nagasaki commemorated the 11th anniversary of its atomic explosion. Sixteen nations were represented, including Russia, Red China, and their satellites. There were the usual denunciations of the use of atomic weapons in war. A public announcement was made of the death of a 14-year-old girl, allegedly a victim of the atom bomb when she was 3 years old. At the time of exposure she showed no skin lesion or any other harmful effects save some superficial cuts from broken glass. She was apparently normal in every way until a year ago, when she began to complain of generalized weakness. The cause of her death was officially given as granulocytic leukemia due to exposure to atomic radiation. She was the 12th such victim to be reported this year. Japan still has over 6,000 living victims. The government has appropriated an additional sum of one million dollars to augment the effort to give them proper medical aid.

NORWAY

Carbutamide.—Dr. S. Aarseth reports on the treatment of 16 diabetics with carbutamide (*Tidsskrift for den norske laegeforening*, Sept., 1956). In nine patients the response was satisfactory. The patients who responded best were middle-aged or elderly, particularly those who were obese and whose disease was mild. As the diabetes is often a combination of different types, it may be difficult to anticipate the reaction of a given patient to this drug. It does not replace insulin, nor does it eliminate the need for dietetic measures. It works only if insulin is present in the body. Though disappointments were frequent with young patients, they were not the rule, and in a 13-year-old diabetic girl, complete normalization of the blood sugar level was achieved with the drug. Attempts to readjust by means of carbutamide the blood sugar level of diabetics whose disease is already stabilized by insulin revealed the risk of provoking acidosis and coma. Hence the author recommends confining any such attempt to the hospital. Diabetic acidosis and coma are contraindications to the use of carbutamide, which is ineffective in patients with these conditions. It should also be withheld in the presence of other acute complications of diabetes. Allergic skin reactions and renal insufficiency are also contraindications. Before trying carbutamide the patient should give a weight-reducing diet a fair chance. The treatment of diabetes with carbutamide is still experimental.

MEDICAL LITERATURE ABSTRACTS

INTERNAL MEDICINE

The Number of Blood Cultures Necessary to Diagnose Most Cases of Bacterial Endocarditis. J. Belli and B. A. Waisbren. Am. J. M. Sc. 232:284-288 (Sept.) 1956 [Philadelphia].

The records of 82 patients with bacteriologically proved bacterial endocarditis who were seen at the Milwaukee County General Hospital between 1938 and 1954 were examined to determine how many blood specimens had to be drawn before a positive blood culture result was obtained. The ages of the patients ranged from 16 to 71; 20 were women and 62 men. The causative organism was Streptococcus viridans in 35 cases, nonhemolytic streptococci in 15, and Micrococcus pyogenes in 28. Other organisms were found in four cases. Three of the patients infected with Str. viridans and eight of those infected with other bacteria had received penicillin prior to the time the first blood was drawn. In 77 of the 82 patients the first positive blood culture was obtained within the first five cultures. Fifty-two of the cases were diagnosed by the first sample drawn. In no cases were more than 10 cultures needed to make the diagnosis. Forty-one per cent of all samples drawn had positive cultures. This study indicates that after five sterile blood cultures the possibility of making a bacteriologically proved diagnosis of subacute bacterial endocarditis decreases. Under these circumstances it is justifiable, therefore, to begin therapy in order to reduce valve damage and other complications of this disease.

Prolonged Use of Arterenol for Shock Following Myocardial Infarction with Patient Survival. I. S. Siglin. A. M. A. Arch. Int. Med. 98:372-376 (Sept.) 1956 [Chicago].

The author describes the case of a 52-year-old woman in whom emotional trauma precipitated a severe myocardial infarction at a time when her status anginosus seemed relatively well controlled. For one week after the infarction the patient presented a gradually progressive shock-like picture. Treatment with 16 mg. of levarterenol (Levophed) bitartrate in 1 liter of 5% dextrose in water by continuous intravenous drip was started when her blood pressure ran between 60/50 and 74/58 mm. Hg for over two hours despite intermittent intramuscular administration of vasopressors such as mephentermine. On the second day of the levarterenol therapy, which was continued for two weeks, severe pulmonary edema with loss of pulses and coma necessitated the use of tourniquets and positive-expiratory-pressure oxygen. The acute left heart failure lasted for six hours. One cubic centimeter of meralluride (Mercuhydrin) sodium was given intramuscularly and daily thereafter because of the pronounced dyspnea, orthopnea, pulmonary rales, and roentgen ray evidence of severe pulmonary congestion with marked cardiac enlargement.

After an initial dose of 100 mg. of cortisone given slowly intravenously on the fourth day of the levarterenol therapy, 25 mg. of cortisone was administered intramuscularly daily for one week. Levarterenol was withdrawn after a total dose of 402 mg. had been given in the course of 14 days. Drug fever apparently resulted from the administration of meralluride for 16 days but subsided after discontinuation of the mercurial therapy. Fever did not recur when mercaptomerin (Thiomerin) sodium was used as a diuretic. Thereafter recovery was slow but steady. After six months, the size of the patient's heart had returned virtually to normal and the lungs were completely cleared. Two years later, the patient led a normal existence, with only a rare anginal attack precipitated by emotional upsets or by walking in cold weather against a strong wind.

The gradually progressive shock-like picture with heart failure was reversed after 14 days of continuous sympathomimetic stimulation with levarterenol along with 7 days of corticosteroid therapy. The difference between failure and success in treating shock rests with early treatment before irreversible changes occur. This requires close observation of the patient and a change from frequent intramuscular injections of vasoconstrictors to continuous intravenous levarterenol drip with its greater ease of pressure control, as soon as it becomes impossible to maintain an adequate blood pressure by intermittent therapy. Since levarterenol apparently does not increase myocardial irritability, it may be that earlier use of this potent vasoconstrictor before frank evidence of vascular collapse sets in might increase the salvage rate in severe hypotension associated with myocardial infarction. Decrease in urinary output may be used as an indicator for strenuous antishock therapy in border-line cases of clinical shock. Constant care to see that the levarterenol solution does not escape from the vein is necessary.

Cortisone and Cortisone-like Substances in the Treatment of Tuberculous Meningitis. I. Santopadre and G. Silanos. Minerva med. 47:468-473 (Aug. 29) 1956 (In Italian) [Turin, Italy].

Fifty-one patients with tuberculous meningitis were treated with cortisone and cortisone-like substances in addition to the classic therapy of alternated cycles of streptomycin and isoniazid. This treatment was given at once or within 10 days to 30 patients; in the other 21 hormones were added to the antibiotics as soon as the condition of the patients made it possible. The hormone was given either orally or by injection in courses of 20 to 25 days each. Beginning doses of cortisone were 100 mg. for adults, 50 mg. for children, and 15 to 20 mg. for sucklings. Beginning doses of prednisone and prednisolone were: 30 mg. for adults, 15 mg. for children, and 10 to 15 mg. for sucklings. The doses were diminished progressively until the suspension of the treatment. The effects of the treatment on the general condition of the patients were very good. Comatose and precomatose forms were favorably influenced. Fever was checked and in some cases the temperature fell to almost critically low values. A high protein level in the spinal fluid and the occurrence of spinal fluid block were noticed. Hydrocortisone administered by spinal injection gave very good results. Paralysis of the cranial nerves was markedly affected. Untoward side-effects were not observed.

Subacute Thyroiditis: Report of Three Cases Treated with Cortisone. A. Moldover. A. M. A. Arch. Int. Med. 98:322-327 (Sept.) 1956 [Chicago].

Subacute thyroiditis is known under several names, such as de Quervain's acute recurrent, pseudotuberculous, and giant-cell thyroiditis. The term subacute thydroiditis, which is the term most frequently used today, distinguishes subacute thyroiditis from the suppurative and nonsuppurative forms, which last only a few days, and the chronic forms, Hashimoto's and Riedel's struma, to which it is not related. The author reports his observations on three patients with subacute thyroiditis and on one patient with carcinoma of the thyroid that closely mimicked thyroiditis. In the first patient, a 41-year-old woman, subacute thyroiditis was at first not recognized. The first symptom was severe pain at the base of the throat radiating to the left side of the neck, head, and ear. At the same time she had a short dry cough. Three weeks later she had temperature rising from 100 F (37.8 C) in the morning to 102 F (38.9 C) in the afternoon. She was treated with penicillin and oxytetracyline (Terramycin), but after two weeks the fever remained unchanged. The thyroid was symmetrically enlarged, firm, and exquisitely tender. She had tachycardia and some enlarged nodes in the axillas. She was hospitalized and was given daily, for 12 days, 150 mg. of propylthiouracil without any effect.

The place of publication of the periodicals appears in brackets preceding each abstract.

Periodicals on file in the Library of the American Medical Association may be borrowed by members of the Association or its student organization and by individuals in continental United States or Canada who subscribe to its scientific periodicals. Requests for periodicals should be addressed "Library, American Medical Association." Periodical files cover 1947 to date only, and no photoduplication services are available. No charge is made to members, but the fee for others is 15 cents in stamps for each item. Only three periodicals may be borrowed at one time, and they must not be kept longer than five days. Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

After that, 25 mg. of corticotropin was given for 10 days, and then it was replaced by cortisone. It is not likely that the duration of the disease was shortened by cortisone. However, by the administration of cortisone the patient was kept symptom-free and able to continue her normal activities, whereas without this medication she might well have been invalided during the entire period. The return of symptoms on premature cessation or reduction of the dose of cortisone emphasizes the importance of continuous therapy until signs of the disease (tenderness and enlargement of the gland, elevated sedimentation rate) have disappeared. In the second patient there was immediate response to cortisone. The third patient had creeping or migrating thyroiditis, in which at first only one lobe is involved and later the other lobe becomes enlarged and tender. The disease ran its usual course, but with cortisone the temperature came down to normal and all the symptoms disappeared within a few days instead of weeks or months. Subacute thyroiditis may be confused with carcinoma, but the two conditions can be differentiated by watching the effect of the administration of cortisone for two or three days.

Analysis of Bronchoscopic Report in 185 Cases of Bronchial Carcinoma. A. E. Paletto, E. Masenti and F. Viglione. Minerva med. 47:342-348 (Aug. 11) 1956 (In Italian) [Turin, Italy].

The authors report bronchoscopic findings in 185 cases of bronchial carcinoma. Bronchoscopic appearances and pathological findings obtained from the removed tissue were compared. Patients were divided into three groups. The first group was characterized by the presence of neoplastic tissue and ulcerations that were directly visible. To the second group belonged patients in whom the bronchial morphology had been markedly altered by the disease. These alterations resulted in stenosis, rigidity, hypomobility, and deformity. To the third group belonged patients whose bronchoscopic findings were negative or in whom manifestations of an inflammatory type were present.

Histological diagnosis based on biopsy was positive in 110 cases (59%), probable in 66 (35%), and negative in 18. Endoscopic examination is quite reliable in indicating whether a patient should be operated on. Comparison of the bronchoscopic and the pathological findings showed that in the patients of the first group the neoplastic infiltration was the same as that detected by bronchoscopy; in the second and third groups the spread of the tumor was much wider than that indicated by bronchoscopy. Early symptoms in relation to the bronchial syndrome of irritation did not indicate any substantial differences between the three groups. The symptoms had lasted longer in patients of the first group than in those of the second and third groups.

Evaluation of Adrenal Cortical Function by Stimulation with Corticotropin (ACTH). N. H. Engbring, R. B. Truitt and W. W. Engstrom. A. M. A. Arch. Int. Med. 98:257-265 (Sept.) 1956 [Chicago].

Determining the concentration of steroids in urine or blood frequently fails to differentiate patients with adrenal insufficiency from those with intact adrenals. The capacity of the adrenal cortex to respond to stimulation was tested by combining the administration of corticotropin with methods that measure the concentration of adrenal hormone. Administration of from 20 to 25 U. S. P. units of corticotropin in a dextrose solution over a period of from 5 to 10 hours will evoke a maximal response in adrenal cortical function during the period of infusion that will be reflected in the urinary steroid excretion. A single infusion may be sufficient to establish the integrity of the gland, or repeated infusions on three or more successive days may be necessary before an unequivocal rise in urinary steroids is observed. With the introduction of more uniformly potent preparations of repository corticotropin, which can be given intramuscularly and which are capable of causing prolonged adrenal cortical stimulation, a simpler technique became available. The results obtained from testing with these preparations were compared with those obtained with the intravenously administered corticotropin. Corticotropin was given intravenously to 35 patients and the long-acting intramuscular corticotropin to 22 patients. Most of the patients had chronic illnesses. In a few instances the studies were made to exclude a diagnosis of Addison's disease, which had been suspected from clinical or other laboratory evidence; further follow-up disproved the existence of adrenal insufficiency. Some of the tests were made to determine the response in patients with relatively acute or self-limited disorders. Since patients with acute, and especially those with chronic, illnesses are the persons in whom it is most difficult to exclude adrenal cortical insufficiency, and since in these the urinary steroid excretion is frequently depressed, it was felt that control studies should be performed on sick patients rather than on healthy persons. For comparison, similar tests were carried out on four patients with Addison's disease and six patients with anterior pituitary insufficiency.

Either of the two methods induced a significant rise (100% or greater if the control level was above 2 mg. and 200% or greater if the control value was very low, i. e., less than 2 mg.) in either the urinary 17-ketosteroids or the corticosteroids in 54 of 57 patients studied. When an insignificant rise occurred in one urinary fraction, there was usually a significant rise in the other, the corticosteroids being the more sensitive indicator of adrenal activity. The results obtained by the use of intramuscular repository corticotropin were more conclusive than those with intravenous corticotropin given over a period of five or six hours. No doubt much longer or continuous periods of infusion of intravenous corticotropin would have given better results, but the technique is inconvenient. The measurement of the increments in urinary steroids under the influence of corticotropin provides an accurate, safe, and direct test of gross adrenal cortical function. It is likely that tests of this nature will largely replace older tests for chronic adrenal cortical insufficiency, especially in patients with complicating illnesses. In view of the considerable individual variations in steroid output, it was not possible clearly to differentiate patients with known anterior pituitary insufficiency from sick patients with intact adrenal and pituitary function. Therefore, it is not likely that these techniques are sufficiently quantitative to detect "potential" adrenal cortical insufficiency, such as might be present in a person who has received hormone therapy.

Proctosigmoidoscopy in the General Physical Examination: An Analysis of 5,158 Examinations. E. L. Crumpacker, J. P. Baker, H. C. Ballou and others. A. M. A. Arch. Int. Med. 98:314-321 (Sept.) 1956 [Chicago].

A proctosigmoidoscopic examination is part of the general physical examination of male patients at the Greenbrier Clinic, a diagnostic medical clinic at which approximately two-thirds of the patients are examined under company-sponsored executive health programs. Proctosigmoidoscopy is performed by the internist. Most examinations are carried out in the morning. If the patient has had a morning bowel movement, frequently no further preparation is needed. If feces are encountered, a low enema of sodium biphosphate and sodium phosphate (Phospho-Soda) solution is administered. This results in excellent preparation in nearly all patients. An attempt was made to pass the sigmoidoscope as far as safely possible. Quite frequently it was impeded at 16 to 17 cm. by angulation or spasm of the colon. A total of 5,158 examinations were performed on 2,401 men. Rectal or sigmoidal polyps or both were discovered in 161 patients (6.7% of patients examined, 3.1% of the total examinations). As expected, polyps were most often discovered on the first examination (3.9%), but a high yield was also obtained on the second annual examination. Thereafter, there was an almost constant finding of slightly more than 2% on each subsequent annual examination. In 113 instances the polyps were solitary, but in 48 from two to "many" were observed. They were located from 3 to 25 cm. from the anal margin; only 40 (25%) were less than 10 cm. from the anus; and only four were felt on digital examination of the rectum. Seventeen (10.6%) of the 161 patients gave a history of rectal bleeding.

All patients with polyps were urged to consult a proctologist for removal of the neoplasms. Since many surgeons fulgurate small polyps without biopsy, the authors received pathological reports in only 53 instances; 36 were said to be benign adenomatous polyps; 8 contained invasive carcinoma; 8 others were reported as carcinoma in situ, hyperplastic polyps, or atypical hyperplasia; one was a carcinoid. Three cases of previously unsuspected multiple polyposis of the colon were discovered by the combination of routine proctosigmoidoscopy with follow-up double-contrast barium-enema studies. Carcinoma of the rectum or colon often develops from benign adenomatous polyps. Digital examination and barium-enema studies will demonstrate a small percentage of rectal polyps, but only proctosigmoidoscopy can be relied upon. One in seven patients with rectal and sigmoidal polyps will have neoplasms at a higher level in the colon. Polyp detection is frequently cancer detection and more frequently cancer prevention. Proctosigmoidoscopy should be a part of every general examination of adults.

Mediterranean Anemia in an Adult Negro. J. E. Norris, H. H. Hanson and R. K. Loeffler. A. M. A. Arch. Int. Med. 98:356-364 (Sept.) 1956 [Chicago].

The authors describe a case of Mediterranean anemia in a 32-year-old Negro woman. She was completely asymptomatic until the age of 19 years, when splenomegaly was accidentally detected. Subsequently, she was gainfully employed, was not incapacitated, and was first seen at Herrmann Hospital in Houston, Texas, at the age of 32, because of acute biliary colic, jaundice, and menorrhagia. The menorrhagia contributed to her anemia and was relieved by hysterectomy. The subsequent course proved that a stone associated with acute biliary colic was the cause of the jaundice. Mediterranean anemia is not punctuated by hemolytic crises of this degree. Fourteen months after the hysterectomy she was readmitted to the hospital for acute pyelonephritis. Except at the time of these incidental complicating illnesses, the patient was unaffected by her anemia. The diagnosis of Mediterranean anemia was established by physical examination, erythrocyte hemoglobin analysis, and family studies. The patient was in good health, was gainfully employed, and was asymptomatic at a recent follow-up. Splenectomy was decided against, as the red cell survival was normal.

The fact that many persons with Mediterranean anemia lead a relatively asymptomatic normal existence is not well known, nor is it always realized that no race or age is exempt from this disease, although it is rare in Negroes. The consensus regarding the mode of inheritance of Mediterranean anemia is that the severe, fully developed syndrome is inherited as a single dominant gene variably expressed; thus, the homozygous form of the disease manifests itself in the severe classic anemia terminating fatally early in life, and the heterozygous form only in the characteristic changes in the erythrocytes causing no symptoms. Patients with the milder forms of the disease may survive through the fourth and fifth decades. Establishing the exact diagnosis in an adult Negro presents a major cooperative task. A study of the family and hemoglobin analysis are essential. The triad observed in the patient consisted of increased clearance rate, relatively high plasma iron concentration, and poor incorporation in circulating red cells. The same pattern was observed by the authors in five patients with severe Mediterranean anemia and in four patients with pernicious anemia. The fact that Mediterranean anemia is primarily a defect in hemoglobin synthesis and red cell production and not a hemolytic process interrupted by crises is emphasized.

Identification and Significance of Platelet Antibodies. J. L. Tullis. New England J. Med. 255:541-551 (Sept. 20) 1956 [Boston].

A simple method for the clinical demonstration of antiplatelet antibodies is described. Many cases of purpura, especially idiopathic thrombocytopenic purpura and hypersplenism, are due to the development of immune antiplatelet antibodies. The differentiation of these cases from non-antibody-induced purpura is of considerable clinical significance, chiefly because of new therapeutic agents: adrenocortical hormones and platelet transfusions. Thrombopenia secondary to deficient platelet production, as in metastatic cancer, leukemia, or radiation, generally is not on an antibody basis. Such cases respond best to platelet transfusions. Primary idiopathic thrombocytopenic purpura, hypersplenism, and neonatal purpura, on the other hand, are frequently due to the presence of circulating antiplatelet antibodies. Such cases respond best to splenectomy or adrenocortical hormones or both. The transfusion of platelets, in these cases, could theoretically lead to an aggravation of the underlying disorder. The test consists of a simple mixture of preserved platelets (as antigen), unknown serum (as antibody), and a small amount of human complement. The mixture is incubated at 37 C and studied at 45 and 90 minutes. Normal serum incubated in this manner will cause little or no decrease in platelet count, whereas serum containing platelet antibodies will cause a decrease in count secondary to agglutination or lysis or both. The test serum is treated to remove all components of the coagulation system before addition to the incubation mixture. The antibody titer remains essentially unaffected by this treatment. As a result of this treatment, any subsequent interaction between platelets and serum can be ascribed to antigen-antibody reactions. A normal control serum is tested simultaneously as a standard.

The test requires no elaborate equipment, but scrupulous attention must be paid to the proper preparation of the serum and performance of the platelet counts to give reliable results. Use of this test as a screening procedure in diverse thrombopenic and hemorrhagic disorders revealed that in 57% of all patients with idiopathic thrombopenic purpura, 66% of all patients with hypersplenism, and 60% of all patients with neonatal purpura tested in this series the disease was due to circulating antiplatelet antibodies. Secondary thrombopenic purpura does not give rise to a positive antibody test except in rare cases. The finding of a positive antiplatelet-antibody test result in an undiagnosed case of thrombopenic purpura is strong evidence against the presence of obscure leukemia or metastatic cancer. The serum factor that gives rise to antiplatelet-antibody tests can be shown to be an antibody by immunologic and chemical tests.

A Family Epidemic of Psittacosis with Occurrence of a Fatal Case. R. L. Prouty and W. S. Jordan Jr. A. M. A. Arch. Int. Med. 98:365-371 (Sept.) 1956 [Chicago].

The authors describe four cases of psittacosis occurring in a family of 12 persons consisting of a 40-year-old Negro minister, his 37-year-old wife, and their 10 children between the ages of 2 and 18 years, who were exposed to two apparently healthy parakeets. This family epidemic of psittacosis resulted in the death of the father and infection of the mother and two children aged 16 and 18 years, with manifestations ranging from severe illness to mild symptoms. Three of the four patients with symptoms had serologic evidence of psittacosis. A diagnostic antibody titer was found in the serum of a fifth member of the family, a 10-year-old boy who had cleaned the bird cage only once. The cage was usually cleaned by his 14-year-old brother, who, despite his more intimate contact with the birds, had neither symptoms nor antibodies. The remaining six members of the family also did not have symptoms or antibodies.

Psittacosis viruses were isolated from the lungs of the patient who died and from one of three parakeets obtained from the store in which the two birds given to the family were purchased The increasing number of cases of psittacosis in humans calls for a reconsideration of control measures, including education of the public and legislation regulating the importation and sale of psittacine birds.

Causes, Origin and Prevention of Endemic Goiter. H. J. Wespi Munchen. med. Wchnschr. 98:1150-1157 (Aug. 31) 1956 (In German) [Munich, Germany].

Of the two types of endemic goiter, i. e., the diffuse and the nodular, the first occurs most frequently in newborn infants, children, and adolescents. While nodular goiter, as a rule, is not reversible, diffuse goiter shows a satisfactory response to the administration of iodine. The author's observations at the gynecologic clinic in Zurich and at the department of obstetrics and gynecology of the Canton Hospital in Aarau, Switzerland, convinced him that it is in newborn infants that normalization of the condition of the thyroid gland by adequate iodine prophylaxis is manifested most rapidly. The supply of iodized salt (with the dose of iodine varying from 5 mg. to 20 mg. of potassium iodide per kilogram of salt) to pregnant women resulted in the reduction of the incidence of goiter in newborn infants from 20.7% (without iodine prophylaxis) to 6.4% (with a dose of 5 mg. of potassium iodide) and to 2.6% (with a dose of 20 mg. of potassium iodide).

An addition of 5 mg. of potassium iodide to each kilogram of salt used not only for cooking purposes but also in bakeries, butcher shops, and for cattle feeding, was introduced gradually in all the cantons of Switzerland between 1922 and 1940, and only in a few of them was the iodine dose increased to 10 mg. of potassium iodide per kilogram of salt on the recommendation of the government. As a result of this general measure endemic goiter practically disappeared, not only in the newborn infants but also in school children and in adolescents. While in the first two decades of the 20th century up to 65 of each 1,000 recruits had been found unfit for active military service, this incidence was reduced to 39 per 1,000 in 1923; a further decrease occurred continuously to 1 per 1,000 in 1940 and to even less in the following years. In addition to the reduced incidence of endemic goiter, the incidence of its complications, including cretinism and deaf-mutism, was also reduced considerably. The number of deaf-mutes dropped from 12 to 16 among 10,000 children born in 1922 to 4 to 6 among 10,000 children born in the period between 1940 and 1945, and of these deaf-mutes not one was a cretin. Despite the introduction of iodized salt used for cooking purposes as a general measure, the incidence of toxic diffuse goiter or of hyperthyreosis was not increased but rather somewhat reduced in Switzerland. Exogenous iodine deficiency is considered the main factor in the origin of endemic goiter. Consequently, a sufficient supply and uptake of iodine must be secured for its prevention. The addition of iodine to the salt used for cooking purposes in doses that ensure a daily supply of from 100 to 200 gammas of iodine, regulated according to local eating habits, is recommended as a simple, safe, and harmless means for the prevention of goiter in endemic areas.

Hemorrhagic Thrombocythemia: A Blood Coagulation Disorder. T. H. Spaet, S. Bauer, and S. Melamed. A. M. A. Arch. Int. Med. 98:377-383 (Sept.) 1956 [Chicago].

The authors report hemorrhagic thrombocythemia resulting from polycythemia vera in a 71-year-old woman. In the course of five years the patient had repeated episodes of gastrointestinal bleeding and other hemorrhagic manifestations, such as massive, spontaneous epistaxis, many of which were treated with blood transfusions. Two 1,000-r courses of x-ray therapy were given to the gastric area in an attempt to reduce gastric acidity. Once, whole body irradiation, 35 r, was given to depress the blood platelets. For almost two years after this treatment the patient appeared to be relatively free of hemorrhage. Except for this period, the course of the disease was characterized by a persistent elevation of blood leukocytes and generally an increase in platelets reaching 10 million per cubic millimeter. The blood coagulation time, prothrombin, prothrombin consumption, fibrinogen, and clot retraction were all normal. The heparin clotting time was found to be definitely shortened. The patient's platelets displayed anticoagulant activity in the thromboplastin generation test when used at circulating levels but behaved normally when diluted to normal levels. Normal platelets were similarly anticoagulant when concentrated to thrombocytothemic concentrations. It is suggested that the fundamental defect in hemorrhagic thrombocythemia is a coagulation disorder resulting from the anticoagulant effect of excess platelets.

When the patient's platelet count had again risen to about 2 million per cubic millimeter and the hematocrit was up to 58 per 100 cc., she was given 4 mc. of radioactive phosphorus (P^{32}) intravenously. In addition, 500 cc. of blood was removed by venesection. Within a month the platelets had fallen to normal levels, where they had remained to the time of the writing of the paper (four months after the administration of the P^{32}). No further hemorrhagic episodes have occurred.

SURGERY

Bilateral Resection in Pulmonary Tuberculosis. A. Falk and N. K. Jensen. Am. Rev. Tuberc. 74:367-375 (Sept.) 1956 [New York].

Falk and Jensen report observations on 60 patients who underwent bilateral pulmonary resections. These 120 (60 bilateral) resections represent approximately one-fourth of all resections carried out between February, 1951, and July, 1955. The very low operative mortality, freedom from complications, and good clinical results in patients with unilateral resections, who had received preoperative antimicrobial therapy for four months or more, led to consideration of the possibility of bilateral lung resection, particularly for patients with known cavitary disease and persistently infectious sputum. Patients selected for bilateral resection included first, patients whose sputum and gastric washings contained tubercle bacilli, who had persistent cavitation, or who had roentgenographic evidence of instability of the lesions after six months or more of chemotherapy. A second category included those with residual disease, particularly if it was allied with atelectasis, fibrosis, or some other destructive process in the lung. Men who are just beginning their life-work or those established in occupations and with family responsibilities (usually less than 50 years of age) should have the advantage of resection to avoid possible future relapse. Public health risks, and the patient who continues to discharge tubercle bacilli in the sputum, were considered for bilateral resection because it provided these patients with the possibility of returning to their homes or communities without the restrictions or stigma of the "good chronic." Resectional therapy also offered to the patient without a home or family the possibility of living in a domiciliary or other arrangement outside the hospital, with obvious social benefits for the individual and a considerable saving in the cost of hospital care.

All 60 patients were white men ranging in age from 20 to 58 years. Forty-six of the patients were less than 40 years old. There were 31 patients with moderately advanced and 29 with far-advanced disease at the beginning of chemotherapy. Far-advanced disease was more frequent in the group under 40 than in the older age groups. The duration of preoperative chemotherapy varied from 1 to 19 months, with the largest number of patients receiving from 5 to 8 months of therapy. The group receiving more than one year of preoperative chemotherapy consisted, with one exception, of those with far-advanced disease. After surgery chemotherapy was continued for a minimum of six months. Since 1954, the minimum total duration of chemotherapy in the resection series has been 18 months. Judging from the incidence of postoperative complications (28 in 120), bilateral resection carries no unusual or added risks. Only three of the 60 patients continued to discharge tubercle bacilli after the second resection. Two of these patients had a postoperative bronchopleural fistula, which healed slowly. Both were also known to have tubercle bacilli resistant to several antimicrobial agents. The third patient had residual tuberculous bronchitis and saccular bronchiectasis of the remaining lung segments. All three now have had sputum cultures free from tubercle bacilli for six months or more. There were no bacteriological or roentgenographic relapses in any of the remaining 57 patients after the second resection and initial sputum conversion. Bilateral resection offers an additional therapeutic approach in selected cases in which sputum conversion has not been achieved by other methods of therapy.

End-to-Side Bypass Homograft Without Resection in Segmental Arterial Occlusion. H. Laufman, R. Hohf, V. Bernhard and O. Trippel. A. M. A. Arch. Surg. 73:418-431 (Sept.) 1956 [Chicago].

The authors performed 19 bypass procedures upon 17 extremities in 15 patients. The patients ranged in age from 46 to 69, and all but one were men. In each instance the indication for surgery was intermittent claudication or ischemic pain of other types associated with an impalpable pulse distal to the occlusion. One patient had gangrene of the great toe. The occlusion was in the femoral artery in 16 extremities, in the iliac artery in 2, and in the iliac-femoral-popliteal in 1. The pathological process in every case was occlusive arteriosclerotic disease. Arteriography was done by the transaortic route in about one-third of the patients and retrograde through a pulsating femoral artery in two-thirds. The occlusions varied from 2.5 cm. in length to total absence of a lumen from the aortic bifurcation to the popliteal artery. The vast majority occurred in the femoral artery. The distal run-off was estimated as poor in two extremities and fair in three. The remaining extremities appeared to have an adequate distal vascular bed.

The authors applied the bypass technique to short as well as to long arterial occlusions on the premise that anastomoses can thus be made far enough away from the occlusion proximally and distally to assure working with the best possible arterial wall in the host, and with minimal dissection. Furthermore, in an effort to establish the limitations of the procedure, they performed it in certain borderline cases in which the peripheral vascular bed was of questionable patency. The end-to-side bypass lends itself readily to virtually any type of segmental arterial occlusion in the lower extremity. Selection of patients with adequate peripheral run-off appears to be of prime importance, although many with less than adequate distal circulation obtain some benefit. Some of these patients recover a distal pulse but develop postoperative edema of the foot and ankle. Immediate success in restoring distal pulsations was obtained in 15 of 19 bypass grafts. Four delayed failures occurred from six days to four months postoperatively, two as the result of delayed occlusion and two as the result of rupture. The circulatory status of the limb subjected to surgery was not worsened in any case, regardless of failure of a graft to function. There were no deaths. In some instances of failure to restore pulse to the ankle vessels, symptomatic improvement was seen nonetheless. Reoperation was carried out in two instances of failure, with one successful result.

Cardiospasm: Results of Heller's Operation. A. Gammelgaard, J. Iversen and G. Thomsen. Acta chir. scandinav. 111:98-107 (No. 2) 1956 (In English) [Stockholm, Sweden].

Twenty men and 14 women with cardiospasm underwent extramucosal myoesophagocardiotomy (Heller's operation) (35 operations) at the department of thoracic surgery of Rigshospitalet in Copenhagen, Denmark. The approach was by left thoracotomy in 32, by right thoracotomy in one, thoracoabdominal in one, and abdominal in one. There were no operative or postoperative complications except for an operative injury of the gastric mucosa sustained by one patient in the course of myotomy and repaired by suture. Thirty-one patients were followed up for an average of three and a half years. Fifteen patients (49%) obtained excellent results with no complaints, 11 patients (35%) had satisfactory results with only occasional retrosternal oppression on swallowing, and 5 patients (16%) had poor results with recurrence of dysphagia, retrosternal oppression, and rumination. Comparison of preoperative and postoperative roentgenograms revealed improvement in 24 patients, i. e., a gradual decrease in the degree of dilatation and a more rapid emptying through the cardia to the stomach. No regurgitation was observed. The poor results could be ascribed to concomitant disorders such as hiatal hernia, neurinoma in the stomach, epiphrenic hernia, and segmental esophageal spasm, or to technical faults. Heller's operation performed through a left-sided thoracotomy is a satisfactory solution of the surgical problem in cardiospasm, affording clinical improvement in practically all patients. An epiphrenic diverticulum developed during the myotomy in two patients, but it caused symptoms only in one.

Subtotal Gastrectomy for Peptic Ulcer: A Comprehensive Review of Two Hundred Thirty-Six Cases with Emphasis on the Treatment of the Ulcer Which Causes Obstruction. W. S. Caudell, C. Marshall Lee Jr. and C. A. Liebig. A. M. A. Arch. Surg. 73:469-480 (Sept.) 1956 [Chicago].

Caudell and associates present an analysis of 236 patients subjected to a subtotal gastrectomy for peptic ulcer during the five-year period from June, 1949, to June, 1954. A major objective of this analysis was to determine whether it is possible to anticipate technical difficulty before the intervention. It was found that technical difficulties could be correlated with the clinical findings. They were encountered in nearly 70% of the patients with duodenal obstruction or about twice as frequently as in any other group. The duodenal lumen was entered either intentionally or accidentally in 42% of the patients with duodenal obstruction or about four times as often as in patients with duodenal pain. The presence of significant obstruction in peptic ulcer should forewarn the surgeon of a difficult operative procedure and permit him to prepare for it.

The authors strongly endorse the medical management of peptic ulcer in suitable cases. The "conservative" method, however, was often unduly prolonged, to the serious disadvantage of the patient. If failures of medical management were recognized earlier and accepted as such, with a prompt decision in favor of surgical intervention, the incidence of technically difficult, high-risk cases could be substantially reduced. Special attention is given to the importance of adapting the surgical procedure to the needs of the individual patient. The fact that a patient has been scheduled for a subtotal gastrectomy does not necessarily mean that a portion of his stomach must be removed. Some surgeons consider a scheduled gastric resection as a sort of personal challenge to be completed at any cost, and thus probably contributes more than any other single factor to the complications of elective gastric surgery. Although methods of dissecting and closing the duodenal stump are as numerous as the techniques for reanastomosis of the gastrointestinal tract, no single procedure has proved satisfactory in all cases. Suggestions are offered to increase the safety of operations.

The Surgical Complications of Meckel's Diverticulum in Infants and Children: An Analysis of Sixty Cases. C. D. Benson and L. M. Linkner. A. M. A. Arch. Surg. 73:393-398 (Sept.) 1956 [Chicago].

Meckel's diverticulum or remnant of the vitelline duct may cause serious surgical complications in the pediatric age group. The authors reviewed the records of 60 children with such complications, ranging in age from 1 day to 14 years. Nearly one-third of the children were less than one year old, and 75% were under 5 years. The complications observed in this group, in the order of their frequency, were intestinal hemorrhage, abdominal pain, acute intestinal obstruction, umbilical fistula, and perforation with peritonitis. The parenteral administration of fluid and blood is essential to insure a high survival rate, particularly in the newborn and in infants. It is essential to restore the blood volume to near normal levels before attempting surgical treatment in patients in whom moderate to severe hemorrhage is the presenting symptom. The authors adhered to this principle in the 24 patients who had intestinal hemorrhage, and all of them survived.

Mechanical obstruction and intestinal hemorrhage are the most frequent surgical complications of Meckel's diverticulum in the first two years of life. With increasing age, intestinal hemorrhage and obstruction become less frequent but acute inflammation of the diverticulum occurs more often. There were four deaths, or a mortality rate of 6.7%, in the 60 infants and children operated on. All of the four patients who died had acute intestinal obstruction and a gangrenous intestine. Fifteen of the 18 patients who required intestinal resection and anastomosis survived.

Tuberculous Tenosynovitis of the Hand Treated by Combined Surgery and Chemotherapy. M. Fellander. Acta chir. scandinav. 111:142-150 (No. 2) 1956 (In English) [Stockholm, Sweden].

Eight men and 11 women between the ages of 19 and 70 years with tuberculous tenosynovitis of the hand were treated with complete surgical removal of the diseased tendon sheath combined with systemic and local chemotherapy. After excision of the synovial sheath and effective hemostasis, 1 gm. of streptomycin was applied locally. One gram of streptomycin was given intramuscularly once daily for from three to six weeks, or for longer periods in complicated cases. Ten to 14 gm. of aminosalicylic acid (PAS) and 0.3 to 0.4 gm. of isoniazid were given orally daily for the entire period of treatment. Relapses occurred in six patients, but complete recovery resulted from chemotherapy alone in one of these and from reoperation in five. Fourteen of the 19 patients were followed up for from three and one-half to five and one-half years after the first operation. In six of these patients the tenosynovitis involved the volar sheaths at the wrist, in three those on the fingers, and in five the dorsal sheaths at the wrist. No recurrences of the tenosynovitis were observed at follow-up. In one patient a tuberculous synovitis of the wrist developed two years after the operation. In all the other patients the recovery was complete, with a good functional result. The results obtained with combined surgery and chemotherapy were much better than those obtained by the author with both surgical and conservative treatment, and they were distinctly better than those reported in the literature before the advent of chemotherapy. It is advisable to begin treatment with combined chemotherapy for a short period and to observe the patient's response. If there is no response, it is advisable not to wait too long before operating. Otherwise there is danger that the tenosynovitis will spread to the adjacent joint and bone and that destruction of the tendons will occur.

Argentaffin Carcinomas: Report of Twenty-Nine Cases, Six Malignant. W. J. Eldred. A. M. A. Arch. Surg. 73:517-525 (Sept.) 1956 [Chicago].

Twenty-nine argentaffin carcinomas were collected from the postmortem records and surgical pathology files of San Francisco Hospital (University of California Service) and Franklin Hospital in San Francisco, representing the 23-year period from 1932 to 1954. Of these 29 cases, 24 are analyzed. Seventeen patients were treated surgically, and the tumors of the other 12 were found at autopsy. The author regards the term "carcinoid" tumor as undesirable and prefers the term argentaffin carcinoma. Ten of the 29 tumors were appendiceal tumors. Most authors report a higher incidence of these tumors in the appendix than elsewhere. The rest of the tumors were distributed in the gastrointestinal tract as follows: ileum, 9 cases; small intestine (unspecified), 3; rectum, 3; jejunum, 2; duodenum, 1; and cecum, 1. The appendiceal argentaffinoma is frequently found in an appendix removed for inflammation. Three of the present series of ten appendices were inflamed. Appendiceal argentaffin carcinomas have a good prognosis because the tumor is often obstructing and gives rise to symptoms. Thus, early surgery results in removal of the tumor and there is less likelihood of its having progressed to the stage of serosal and lymph node spread than is the case with an identical tumor situated elsewhere in the gastrointestinal tract.

Appendectomy with wide excision of the mesoappendix is the treatment recommended when an argentaffin tumor is found in the appendix. Intermittent obstruction of the small intestine or x-ray demonstration of a filling defect or kinking of the terminal ileum in a middle-aged patient should alert one to the diagnosis of argentaffin carcinoma. Another feature that may prove of diagnostic importance is the association of these tumors with valvular disease of the right side of the heart, sudden flushing of the skin, an unusual type of patchily distributed changing cyanosis, and "asthma." The cause of the syndrome is thought to be substances with vasoactive properties. Serotonin, or enteramine (5-hydroxytryptamine), is most likely to correspond with the signs and symptoms of the syndrome. Recently, it was extracted in considerable amounts from an argentaffinoma. Recognition of the vasomotor symptoms should result in more cases of argentaffin carcinoma being discovered and brought to operation. The radical surgical extirpation of such tumors is often followed by a relatively long and comfortable life for the patient. Removing the primary tumor in patients with extensive metastases often results in arrest of further metastases for several years.

Critically Crushed Chests: A New Method of Treatment with Continuous Mechanical Hyperventilation to Produce Alkalotic Apnea and Internal Pneumatic Stabilization. E. E. Avery, E. T. Mörch and D. W. Benson. J. Thoracic Surg. 32:291-311 (Sept.) 1956 [St. Louis].

Approximately 25% of deaths from traffic accidents are due to chest injuries. A number of patients with severe chest injuries who were rapidly failing with the usual modern means of treatment were quickly stabilized and eventually recovered by the use of continuous mechanical hyperventilation. The first patient treated by this method was a 51-year-old man who had been slowly rolled into an 8-in. space between a diesel locomotive and a steel furnace. He was admitted moribund, in deep shock, with multiple bilateral fractures of ribs; costochondral separations; bilateral tension hemopneumothorax; fractures of the sternum, clavicles, and pelvis; crushing injuries of the liver and genitourinary tract; paralytic ileus; and acute gastric dilatation. Bilateral intrapleural catheter water-trap drainage was carried out along with tracheotomy. The anterolateral chest wall was partially stabilized with soft tissue traction. Long metal pins were passed under the pectoralis and serratus anterior muscles on each side. Spreader bows were attached and traction applied to an overhead frame. Although the paradoxical motion was partially corrected, respiratory acidosis continued because of inadequate ventilation resulting from actual lung destruction and pulmonary edema. Various demand-flow and pressure-cycled respirators were tried, but these machines did not ventilate the patient adequately. The piston-type intermittent-positive-pressure respirator developed by Mörch was then applied, and the patient's condition improved from a semicomatose state of respiratory acidosis to a more alert state of alkalotic apnea. The pH was kept in a range of approximately 7.45. Lung inflation and deflation were mechanically maintained rhythmically and smoothly, with loss of all paradoxical motion. This stopped all overriding and grinding motions of the broken rib ends and promoted their healing. Soft tissue traction was discontinued as soon as it was realized that stabilization of the chest was to be obtained with mechanical ventilation. This was maintained for 30 days until the patient was able to breathe adequately without the assistance of the machine. The patient was discharged from the hospital 51 days after the injury and has returned to his work. The authors used the same principles of management in a number of other severe chest and combined head and chest injuries with equally good results.

The most striking benefit of this mechanical hyperventilation treatment is that it is safe and allows the survival of patients with a seemingly hopeless prognosis. Its chief advantages are correction of paradoxical motion of the chest wall; removal of hypoxia and hypercarbia; absence of pulmonary edema; less sedation is required; no serious deviations in blood chemistry with prolonged mild respiratory alkalosis; no measurable circulatory defects; prompt return of blood chemistry and physiological responses to normal with cessation of hyperventilation; and no late ill-effects. Continuous mechanical ventilation should be applied whenever the function of the chest wall has been impaired, as in crushing injuries of the chest; infections (poliomyelitis, tetanus); muscle disease (myasthenia gravis); trauma to the brain (head injuries, postoperative neurosurgical conditions, cerebral vascular accidents); respiratory depression (industrial poisons, suicide, overdosage of medicaments and anesthetics); and in ventilatory insufficiency following pulmonary resection. Many of these patients now die not of their primary lesions but from complications arising from decreased pulmonary ventilation.

Congenital Atresia of Esophagus. G. H. Humphreys, B. M. Hogg and J. Ferrer. J. Thoracic Surg. 32:332-346 (Sept.) 1956 [St. Louis].

This report deals with 136 cases of congenital esophageal atresia with and without fistula in infants seen at Babies Hospital or born in Sloane Hospital, both now units in the Columbia-Presbyterian Medical Center in New York, in the half century between 1903 and 1953. Over the last decade successful surgical treatment has been possible, and since then larger numbers of infants with this anomaly have been observed. The defect is not so infrequent as the earlier experience suggested; either it was unrecognized or little effort was made to treat it in the earlier period because of the apparent hopelessness of the situation. It is probable that the incidence, about 1 in 3,000 births, has not changed. The type of anomaly in this series was about the same as that described by others; in 122 of the 136 patients the esophagus ended in a blind pouch high in the posterior mediastinum and the lower segment originated in a fistula from the membranous portion of the trachea, the carina, or one of the primary bronchi. All but two of the recoveries occurred in this group. It seems probable that an incomplete cleavage between trachea and esophagus, together with failure of recanalization of the esophagus, will explain all the types of the anomaly. Of the total group of 136 patients, 75 are known to have had other congenital malformations. Among the 104 who died, 93 were examined at autopsy and 61 of these showed other anomalies; of the remaining 11 in whom autopsy was not performed, 5 showed gross associated anomalies. Thus, two-thirds of the infants who died were handicapped by other malformations. In contrast, among the 33 survivors only 9, or fewer than one-third, showed other anomalies.

Of the 101 patients operated on, 32 survived and 29 of these were living and well at the time of this study. Factors influencing survival are the size and degree of prematurity of the infant; the association with other severe malformations; the awareness of doctors and nurses caring for newborn infants of the possibility of the condition and their alertness in recognizing the characteristic symptoms; the promptness with which patients are referred for surgery; the care in preoperative and postoperative management; and the technical aspects of the operation itself. The first two factors are uncontrollable. The others give room for improvement. While occasional patients present anomalies that require multiple-stage procedures before swallowing can be restored, in the majority, successful end-to-end anastomosis of the esophagus is possible, with satisfactory restoration of normal swallowing.

Congenital Diaphragmatic Hernia and Hypoplastic Lung: A Clinical Evaluation. B. B. Roe and H. B. Stephens. J. Thoracic Surg. 32:279-290 (Sept.) 1956 [St. Louis].

A number of reports on congenital diaphragmatic hernia indicate that the condition can be surgically corrected with a low mortality rate, but the authors observed that the compressed and hypoplastic lung in the previously occupied pleural space could not be expanded after removal of the abdominal organs. They studied the hospital records and autopsy protocols of all cases of congenital diaphragmatic hernia in 11 San Francisco hospitals for as long as records were cataloged, up to 20 years. In all, 47 cases were analyzed for pregnancy factors, obstetric course, birth weight, presenting signs, time of operation, operative findings, length of survival, and autopsy observations. They found that the mortality rate in the newborn group was 87% as compared to 12% in the older patients (over 14 days of age), suggesting that natural selection plays an important role in the results. Surgical mortality was 67% in the newborn infants and 8% in the older group. Hypoplastic lung was an associated finding in nearly all patients that came to autopsy. Average combined lung weight was 44% of normal. The lung was found to be undeveloped on the side of the hernia in 10 of the infants who received surgical treatment and in 17 of those who came to autopsy (weight ratios of 0.13 to 0.91).

It is possible that clinical inexperience, technical difficulties, and other hazards of operating on the newborn infant are responsible for the high mortality rate. Surgical results are distinctly better despite these same disadvantages after two weeks of life and better respiratory compensation. The process of natural selection in the early neonatal period removes the patients with inadequate respiratory capacity. This period is also of positive value in improving the gradually acquired ventilatory capacity of an infant and rendering him a better surgical risk after a few days despite the hernial contents in the chest. Proponents of early surgical intervention argue that no harm is done by an unsuccessful attempt to help those whose unpredictable fate has already been sealed. They hope to salvage the borderline patient who might have an expansible lung and survive if the mechanical pressure were removed but who would not otherwise survive. The authors believe that more patients with marginal respiratory capacity at birth will survive if surgical intervention is delayed 10 days than if it is carried out immediately. Those with inadequate capacity will die whether they are operated on or not.

Hypophysectomy in the Treatment of Advanced Cancer of Breast. B. S. Ray and O. H. Pearson. Ann. Surg. 144:394-406 (Sept.) 1956 [Philadelphia].

Ray and Pearson discuss the benefits of hypophysectomy in the management of advanced mammary carcinoma in women. In the 22-month period between March, 1954, and December, 1955, 75 operations were performed on 74 women. Evaluation of the results is based on a follow-up of from 3 to 24 months. The operation employs a coronal scalp incision behind the hairline; opening of the right frontal bone; elevation of the right frontal cerebral lobe; division of the right olfactory nerve; division of the hypophysial stalk; enlargement of the opening in the diaphragm sellae; removal of the pituitary gland by curettement and suction followed by exposure of the sella turcica to Zenker's fluid; and closure of the wound without decompression.

There were seven deaths in the first 30 days after the operation, though only three could be attributed directly to the operation. Of the 67 patients who survived the operation, 36 had objective remission of their disease and 31 were not benefited. New remissions can be obtained by hypophysectomy in patients who derived temporary benefit from castration or from a combination of castration and adrenalectomy. Every patient who was temporarily benefited by castration obtained a new remission after hypophysectomy, and 4 of 11 patients who had had both castration and adrenalectomy obtained a new remission after hypophysectomy. It is suggested that if hypophysectomy is not employed as the initial ablative operation in altering endocrine influence on the disease, it is probably preferable to adrenalectomy as a second operation after castration. The survival period is more than twice as long in patients who obtain a remission after hypophysectomy as it is in those who do not, and the difference should be even greater when more time has elapsed.

Breast Cancer and Pregnancy: Report of 49 Cases Followed 5 Years. T. T. White and W. C. White. Ann. Surg. 144:384-393 (Sept.) 1956 [Philadelphia].

The authors collected 49 cases in which mammary cancer was associated with pregnancy from six hospitals in Seattle and from three hospitals in New York City. Of 11 patients treated for cancer of the breast while they were pregnant, 4 had lesions limited to the breast. Two of these four women died within a year, whereas two survived for 14 years, one still being free from cancer after this interval and the other dying from cancer in the opposite breast. All of the seven women who had involvement of the axillary lymph nodes died within four years. In 14 patients, the tumor was first noted during pregnancy and treatment was deferred until the nursing period. The average delay in treatment was 11 months. There were 3 such patients with disease localized to the breast and 11 in whom axillary nodes were involved. One of the three patients with localized disease survived seven and one-half years, while the other two survived three and one-half years at the end of which one was dead and the other was lost to follow-up. All of the 11 patients with axillary spread were dead in less than five years. The 12 patients with tumors found and treated during nursing appeared to have been treated more promptly than those in whom the tumor was first found in pregnancy. There was an average delay in treatment in this group of 3½ months and an average survival period of 52 months. Three of the 5 without axillary spread and 2 of the 7 with it in this group of 12 survived five years or more. Of the 12 patients operated on for breast cancer who later became pregnant, 7 survived 10 years or more, 2 of these for 34 years without recurrence. The interval between operation and subsequent pregnancy in all was four years or less.

The authors conclude that about one-third of the patients who develop breast cancer during the child-bearing period will have pregnancy as a complication during or after the occurrence of the cancer. Patients treated during pregnancy or nursing without spread of the disease beyond the breast have a prognosis similar to that which prevails in the absence of pregnancy or lactation. Patients with axillary spread of the cancer are usually in an advanced state of disease because of delay in treatment. The prognosis of patients who become pregnant after operation appears to be unusually good. Although abortion, spontaneous or induced, did occur in six patients, there was no evidence that it had produced any benefit.

Causes of Reintervention After Gastric Resection for Peptic Ulcer: A Contribution to the Study of the Complications in Stomach Operations. A. Medici and L. Contorni. Ateneo parmense 27:445-471 (May-June) 1956 (In Italian) [Parma, Italy].

The authors studied the causes for reintervention after gastric resection for peptic ulcer and the late complications that occur after operations on the stomach. All the cases treated in their institute in the last four years were critically reviewed. From January, 1952, to February, 1956, of a total of 2,828 surgical interventions, 457 were concerned with gastroduodenal pathology. Reintervention on the jejunal stoma was performed in 53 or 11.67% of all cases. In 43 cases reintervention was made necessary by lesions that occurred on the stomach or the duodenum or by some acute complication such as perforation. Only from 80 to 85% of the patients were well after the first operation. Postanastomotic peptic ulcer is the predominant chronic or late complication that calls for reintervention. Polyposis of the anastomotic stoma is a very rare lesion after gastroduodenal resection for peptic ulcer.

Bleeding Esophageal Varices: A Study of the Cause of the Associated "Hepatic Coma." W. V. McDermott Jr., J. Wareham and A. G. Riddell. Ann. Surg. 144:318-335 (Sept.) 1956 [Philadelphia].

In a group of 118 patients with portal hypertension who entered the hospital with massive gastrointestinal bleeding, 68 died. Only 18 of these 68 deaths were directly attributable to exsanguination, and 12 were due to causes not related to hepatic function. Thirty-eight of the patients who died in coma did so without manifesting either severe shock or uncontrollable and exsanguinating hemorrhage. This indicates that blood loss alone does not account for the high mortality. This paper is concerned with experimental and clinical studies designed to clarify the role of massive gastrointestinal hemorrhage in precipitating the so-called hepatic coma. Ten experiments were carried out on five healthy adult mongrel dogs in whom an Eck fistula had been constructed from 1 to 20 months before the experiments. Normal adult mongrel dogs on which three experiments were done were used as controls. The implications of these experiments on animals are discussed in connection with the results of clinical studies on 18 patients with bleeding esophageal varices and concomitant central nervous system symptoms who entered the Massachusetts General Hospital during the years from 1953 to 1955.

All of the patients studied showed striking elevations in the peripheral blood ammonia level, and the degree of elevation correlated well with the severity of the central nervous system symptoms. Some biochemical abnormalties associated with the introduction of blood into the gastrointestinal tract in the presence of spontaneous or surgically constructed portal-systemic shunts suggest that the syndrome of hepatic coma so commonly seen in patients with bleeding esophageal varices is due to ammonia intoxication. A program for the management of bleeding esophageal varices is outlined. Control of hemorrhage is of primary importance, because, even though there is no apparent threat of exsanguination, it is imperative to prevent the accumulation of a nitrogenous pool in the gastrointestinal tract. This may be accomplished initially by balloon tamponade and, when stabilization has been achieved by transfusions, by direct transthoracic ligation of the varices. Most of the blood can be removed by catharsis. Antibiotics should be given, because by depressing the bacterial count in the gastrointestinal tract the sources of urease and aminoacid oxidase can be controlled. L-glutamic acid has proved to be a valuable adjunct to therapy and may be given orally or parenterally in the glutamate form.

Wound Healing: A New Perspective with Particular Reference to Ascorbic Acid Deficiency. J. E. Dunphy, K. N. Udupa and L. C. Edwards. Ann. Surg. 144:304-317 (Sept.) 1956 [Philadelphia].

Experiments were conducted on 72 male guinea pigs weighing between 250 and 350 gm. Thirty-two animals were used as normal controls and 40 were placed on the standard scorbutogenic diet of Sherman for 20 days before wounding. The control animals were given a diet supplemented with vitamin C in the form of fresh vegetables and oranges. Wounding was done as follows: Under ether anesthesia the back of the animal was shaved and the skin prepared with a 2% isopropyl alcohol solution. Two circular wounds were made on the interscapular area of the back of each animal measuring about 3 cm. in diameter. The skin, subcutaneous tissue, and superficial muscles of the back were excised. Bleeding points, if any, were clamped and ligated with fine catgut. No dressings were applied. The wounds were allowed to heal without any further local treatment. On the 4th, 8th, 12th, and 16th days after wounding, the animals were killed by an overdose of ether anesthesia. One of the two wounds in each animal was utilized for histological and histochemical studies and the other for chemical analyses.

Chemical and histochemical studies provide a new perspective of wound healing based upon a "humoral" as well as a "cellular" approach. Significant differences in the pattern of healing in normal and depleted animals can be detected by these methods. In ascorbic-acid-deficiency fibroplasia, mucopolysaccharide production and the formation of reticular procollagen material are not inhibited and may be considerably increased. The basic defect of repair in ascorbic acid deficiency appears to be one of collagen synthesis. Evidence is presented to show that this defect is corrected within 24 hours after the intramuscular administration of ascorbic acid. A sponge biopsy technique that permits the study of repair by these methods in primarily closed wounds is described. Preliminary observations indicate that it can be applied effectively to a study of wound healing in man.

The Management of Inguinal Hernia in Infancy and Early Childhood. C. W. McLaughlin Jr. and C. Kleager. A. M. A. J. Dis. Child. 92:266-271 (Sept.) 1956 [Chicago].

The authors report observations on a consecutive series of 298 inguinal hernias seen in 240 infants and small children on the surgical service of Children's Memorial Hospital in Omaha. Inguinal hernia was the commonest congenital lesion for which infants and children were admitted to this hospital. Two hundred seventeen of the patients were males and 23 were females. In almost 60% of the children the hernia was noted before they completed their first year of life. Twenty-six infants were admitted with incarcerated hernia, but no strangulation of intestine was observed in an infant. This series of 298 hernias included 20 with associated hydroceles and 5 with hydroceles of the testis. Eleven patients in this group had undescended testes cared for at the time of herniorrhaphy. More than three-fourths of the complicated hernias in this series occurred in infants under 6 months of age. During the past 15 years the authors have recommended the immediate repair of all inguinal hernias regardless of age. While herniorrhaphy is a more difficult operation in a child under the age of 3 months than it is in older children, familiarity with the infant anatomy, the use of fine instruments, and, above all, delicate handling of tissues make it a sound surgical procedure.

Effect of Bilateral Adrenalectomy on Metastatic Choriocarcinoma from Teratoma of the Testis. N. S. R. Maluf, R. K. Loeffler and E. E. Erickson. J. Clin. Endocrinol. 16:1217-1226 (Sept.) 1956 [Springfield, Ill.].

Although it is plausible to consider that the growth of testicular tumors may be under hormonal control, there is no clear example of regression of a testicular tumor or of its metastases after orchiectomy or adrenalectomy except in patients also receiving radiotherapy. In the patient of this report, who had chorionic metastases from a teratoma of the testis, bilateral adrenalectomy produced no apparent benefit. Serial radiographs of his chest showed no change in the growth rate of measured discrete metastatic nodules.

NEUROLOGY & PSYCHIATRY

Prolonged Hypothermia in Treatment of Massive Cerebral Hemorrhage: A Preliminary Report. D. A. Howell, J. G. Stratford and J. Posnikoff. Canad. M. A. J. 75:388-394 (Sept. 1) 1956 [Toronto, Canada].

In massive cerebral hemorrhage death is generally caused by the tentorial pressure cone. The cerebral hemispheres increase in volume, and this swelling displaces the brain-stem downwards, producing ischemia of the posterior diencephalon, midbrain, and pons. Ischemic necrosis continues as long as the pressure remains high in the hematoma, and it usually proceeds more rapidly in patients with high blood pressure. The slower-developing cerebral hematomas in normotensive patients may be evacuated at craniotomy in the first few days of illness. The brain can be made slack and the hemispheres reduced in volume in three different ways: by dehydration, arterial hypotension, and hypothermia. Reducing the cerebral volume by hypothermia has distinct advantages. This was demonstrated in eight patients with massive intracranial hemorrhage. The patients were cooled by means of ice bags in the groins and axillae, alcohol sponging, and fans until the rectal temperature fell to between 32 and 30 C (90 and 86 F). Opening the windows during the Canadian winter hastened the fall in temperature, and once a patient was immersed for an hour in a bath to which ice was added. The patients were placed semiprone to prevent inhalation of vomit, and care was taken to prevent the upper shoulder from dropping forward and obstructing the venous return from the head. Tracheotomy was employed on several occasions to facilitate aspiration of secretions. Chlorpromazine, 50 mg., was given by intramuscular injection at the onset, and half this dose was repeated whenever the patient shivered or vomited.

Hypothermia influenced the course of the disease in every patient. Seven showed some improvement and two survived. Survival of two of eight patients with fulminating spontaneous intracranial hemorrhage is not an impressive result. However, in no case was prolonged hypothermia without influence. The progress of the pressure cone was arrested, and there was a dramatic improvement. Gastric hemorrhage was the most serious complication. It developed in four patients and possibly in a fifth either during the hypothermia or up to seven weeks after the onset of the illness. The authors attribute it to the small superficial ulcers secondary to brain damage of the type described by Cushing. Such ulcers were found at autopsy in two patients. This complication was unexpected, as gastric hemorrhage is not commonly seen in patients with cerebral hemorrhage. Death was averted in later cases by blood transfusions. One patient had a severe nosebleed most easily attributed to hypertension, and another was found, at autopsy, to have an adrenal hemorrhage. Mild uremia developed in all patients, and anuria in three. Pneumonia was a serious complication in three patients. Aseptic venous necrosis developed in two patients, possibly as the result of the negative water balance. Weeping eczema of the scrotum was seen in one patient, possibly caused by prolonged contact with ice bags. Various auricular arrhythmias were transient and harmless. Prolonged hypothermia is a powerful method of reducing the cerebral volume and thereby relieving the acute tentorial pressure cone.

Hereditary Pellagra-like Skin Rash with Temporary Cerebellar Ataxia, Constant Renal Amino-Aciduria, and Other Bizarre Biochemical Features. D. N. Baron, C. E. Dent, H. Harris and others. Lancet 2:421-428 (Sept. 1) 1956 [London, England].

Preliminary studies are reported on a new syndrome that began in 1951 when a boy was hospitalized who apparently had severe pellagra associated with a neurological disorder. His urine contained a consistently large amount of amino acids. This led to many further biochemical investigations, and it soon became apparent that he had a bizarre and hitherto undescribed syndrome. Studies of the boy's relations revealed similar biochemical features in three of his seven siblings, one of whom had been admitted several years previously to the Middlesex Hospital with a similar pellagra-like syndrome. The eight siblings were the offspring of a first-cousin marriage. The most constant clinical feature of this new disease, which has been referred to as Hart's syndrome, or now preferably as "H" disease, is a tendency to develop a rough reddened skin on exposure to moderate sunlight. In two of the siblings, greater exposure led on more than one occasion to a severe rash that appeared identical with that of pellagra. On occasion a severe but fully reversible cerebellar ataxia developed in association with the rash and also (in one of the patients) following infective disease without rash. The older affected siblings are also mentally retarded.

Among the biochemical findings is a constant gross renal aminoaciduria of unique pattern, without other evidence of renal dysfunction. This is the most specific abnormality by which the disease can be identified. There is also a constant large excretion in the urine of indole-3-acetic acid and a less constant large excretion of indican. The feces contain a moderately increased quantity of protoporphyrin. The authors wonder if the immediate biochemical disorder producing the clinical syndrome is an abnormality of nicotinic-acid utilization. In recent years a number of new clinical syndromes have been described in association with gross metabolic disorders. The biochemical disorder usually helps to diagnose the disease since it may be more constant and characteristic than are any of the clinical features. This latter point especially applies to hereditary diseases, where the action of a gene may show itself by a constant gross biochemical abnormality even when the clinical signs remain ambiguous and fluctuate in intensity.

A Psychotherapeutic Technique with Large Groups in the Treatment of Alcoholics: A Preliminary Report. J. J. Armstrong and R. J. Gibbins. Quart. J. Stud. Alcohol 17:461-478 (Sept.) 1956 [New Haven, Conn.].

The authors found that in the early stages of treatment alcoholic patients frequently remain anxious and easily disturbed, with many defenses against obtaining much-needed insight through formal psychotherapeutic interviews. Many alcoholic patients present personality problems that involve difficulties in their dealings with authority. The group setting, however, is often comparable to aspects of a society the patient is used to, in that it is composed of people with similar attitudes, interests, and abilities, but not drinking at the moment. An attempt was made to establish a group with some homogeneity. Originally, the only patients accepted for the group were those who were undergoing or had undergone individual psychotherapy or at least a psychiatric evaluation. Soon patients were directed to the group right from the intake conference. The weekly attendance gradually rose to an average of 35, which prevailed during the period of the present study. Of 32 persons who attended at least 15 sessions, 23 improved, 7 could not be traced, and 2 received no help. The conclusion was reached that the group method of treatment for alcoholics provides certain distinct advantages over individual therapy by lessening the patient's need to reject authority as symbolized by the therapist, reducing anxiety engendered by transference situations, allowing a more permissive setting than rigidly scheduled individual interviews, and permitting a sharing of experiences toward a common goal with others having comparable problems.

Intraspinal Epidermoid Tumours (Cholesteatomas) in Patients Treated for Tuberculous Meningitis. C. Choremis, D. Economos, C. Papadatos and A. Gargoulas. Lancet 2:437-439 (Sept. 1) 1956 [London, England].

Dermoid and epidermoid tumors in the central nervous system are variously called pearly tumors, epidermoid teratomas, dermoid endotheliomas, and cholesteatomas. The usual sites of these tumors are the lumbosacral spinal canal, the middle ear, the vicinity of the pituitary gland, and between the tables of the skull. At the Children's Clinic of the University of Athens the authors recently had occasion to study five children, ranging in age from 7 to 12 years, who had pearly tumors in the thoracolumbar spinal canal. All these children had been successfully treated from three to seven years earlier for tuberculous meningitis. The authors believe that the two conditions are closely related. They think that repeated lumbar punctures in the course of streptomycin therapy may implant epithelial cells which in time form these tumors. They hope that this report will alert physicians to the recognition of a curable condition arising as a complication of the treatment of tuberculous meningitis.

The Pathological Effects of Cerebral Arteriography. T. Crawford. J. Neurol., Neurosurg. & Psychiat. 19:217-221 (Aug.) 1956 [London, England].

Cerebral arteriography is usually without harmful effects; nevertheless, there is inevitably some damage to the arterial wall, and in a very small proportion of cases harmful effects ensue. Crawford reports observations on autopsy material from 75 subjects on whom arteriography had been carried out at intervals varying from two hours to eight months before death. This material came from many different sources and was not confined to the autopsies from a single neurosurgical unit. The most serious ill effects observed were carotid thrombosis and cerebral embolism. It was not possible to assess the frequency of these rare misfortunes. They are more liable to occur in elderly hypertensive arteriosclerotic patients.

Infantile Encephalomalacia with Multiple Cavity Formation. B. J. Alpers, R. A. Farmer and H. E. Yaskin. A. M. A. Arch. Neurol. & Psychiat. 76:229-235 (Sept.) 1956 [Chicago].

The authors report on studies on the brain of a boy who died at the age of 3½ months and in whom encephalomalacia with multiple cavity formation was discovered. The mother was in good health during pregnancy but one week before delivery had an attack of pneumonia. There were no seizures at birth. At 2 weeks of age the infant developed "growling respiration," and at 7 weeks he had a bloody nasal discharge, extending his arms stiffly, and had a staring gaze. At 11 weeks he had attacks of cyanosis, in which he was found to twitch, stiffen out, and clench his fists. He had a generalized convulsion at 14 weeks. Examination at this time revealed that the child was unconscious, with hyperpnea, bilateral papilledema, retinal and subhyaloid hemorrhages, and generalized hyporeflexia. The spinal fluid and subdural fluid were grossly bloody. He had an erythrocyte count of 2,700,000 and 41,000 leukocytes per cubic millimeter, with lymphocytes predominating. He died within a few hours after his seizures.

Numerous cystic areas were found in both gray and white matter of the brain and in the basal ganglia regions, sparing brain stem and cerebellum. Microscopic study revealed pia-arachnoid thickening, profuse gitter-cell accumulation with cyst formation, often focal gitter-cell collections, calcium deposits in some of the areas of necrosis, and areas of only partial destruction of tissue. The blood vessels were on the whole intact, but endothelial swelling was present in some regions and many perivascular spaces were filled with macrophages and mononuclear cells. The features recorded in this case correspond well with those previously reported. Variations in the location and extent of the lesions have been observed from case to case. The outstanding variation in the present case consisted in extensive involvement of both the gray and the white matter. The pathogenesis of the encephalomalacia is not clear.

A Controlled Clinical Study of Chlorpromazine and Reserpine in Chronic Schizophrenia. M. Shepherd and D. C. Watt. J. Neurol., Neurosurg. & Psychiat. 19:232-235 (Aug.) 1956 [London, England].

Shepherd and Watt tried to assess the relative merits of chlorpromazine and reserpine. Twenty-four of the most deteriorated and apathetic female schizophrenic patients in a county mental hospital were chosen. Their ages ranged from 27 to 52 years. The length of stay in hospital varied from 7 to 29 years. Most patients were totally unoccupied, withdrawn, and unsociable. They took no interest in their appearance or personal care and were incontinent of urine. Talk was so seriously disordered that an intelligible conversation was impossible. Many patients were mute; a few were noisy, interfering, hostile, or destructive to clothing and property. The 24 patients were divided into three groups of eight by random selection. The experiment lasted 18 weeks, during which each group of patients received each of three substances—reserpine, chlorpromazine, and placebo, in different orders of administration. Chlorpromazine was responsible for improvement in a significantly higher proportion of cases than reserpine, and, in the doses employed, reserpine was responsible for the great majority of toxic effects observed. No satisfactory explanation for these differences can be offered because of the obscurity attending the mode of action of reserpine. It may be significant that the schizophrenic patients in the present study were chosen not for their aggressiveness and overactivity, as in most of the other studies cited, but because of their apathy and inertia.

Pyridoxine (Vitamin B_6) in Alcoholism. G. W. Atkinson and W. C. Kappes Jr. Virginia M. Month. 83:391-393 (Sept.) 1956 [Richmond, Va.].

Observations were made on 70 unselected patients with alcoholic intoxication. Thirty-five of these patients were given 500 mg. of pyridoxine hydrochloride (vitamin B_6) twice a day, whereas the other 35 served as controls, receiving only the treatment given to all of them. There was no significant difference in the recovery rate of those treated with pyridoxine and in the controls. The excretion rate of the alcohol was not altered by the pyridoxine, and no beneficial effect or change was observed after its use in alcoholic patients who had psychoses and convulsions. Although pyridoxine has been advocated by a number of observers for the treatment of alcoholic intoxication in human subjects, in experiments on mice it has proved ineffective or even dangerous in large doses.

Pseudotumor Cerebri: Benign Intracranial Hypertension. L. M. Davidoff. Neurology 6:605-615 (Sept.) 1956 [Minneapolis].

The author reports on 61 patients between the ages of less than 5 and more than 50 years with "pseudotumor" or benign intracranial hypertension, all of whom had true papilledema. Most of them complained of headache, and many of them had failing vision. All but one had a normal ventricular system as revealed by pneumoencephalography (either ventriculography or lumbar encephalography). The cerebrospinal fluid was under increased pressure but otherwise within normal limits as far as cell count and protein were concerned. Many of the patients complained of diplopia, and these usually showed interference with one or both sixth cranial nerves. In four male and five female patients symptoms developed after otitis media. In 11 male and 12 female patients symptoms developed after infections in the body elsewhere than in the ears or mastoids, or after a head trauma. The last group of 29 patients, 18 of whom were women, gave no history of preceding infection. The peak of the incidence in this group was in the fourth decade of life. Unusual obesity was noted in 3 of the 18 women.

The causation of this condition is still unknown and is probably variable. Patients in whom symptoms are preceded by infection of an ear or mastoid may well have mural thrombi in the superior longitudinal sinus or the major lateral sinus extensive enough to interfere with cerebrospinal fluid absorption. To some extent this may also be true of patients with preceding infection elsewhere than in the ear or mastoid, or with cerebral trauma. In the group of 29 patients in which the syndrome occurred more frequently in women and was more common in the middle decades of life, the condition may have been of a toxic or allergic nature, and in the women it may have been related in some manner to menstrual disturbances of electrolyte balance. Subtemporal decompression was performed in 51 patients and suboccipital decompression in one. In nine patients treatment consisted of dehydration measures and repeated lumbar puncture, after which they were placed on a salt-poor diet; fluid intake was limited, and ammonium chloride or Diamox was administered. The patients were followed up for from one to 22 years. Most of them recovered, but five had complications, which consisted of convulsive seizures in two, a tense decompression and blurring of the disk margins in one, subdural hematoma in one, and a slight degree of diencephalic dysfunction and a somewhat greater degree of focal abnormality at the site of the decompression in one. The prognosis in most patients is excellent, although many months or even several years may be required for the syndrome to subside completely. Because of the favorable outcome in most patients and the uncertainty as to the causation of the syndrome, the term "benign intracranial hypertension," suggested by Foley, especially for those cases not preceded by infection or trauma, seems a desirable one.

Course of Exacerbations of Multiple Sclerosis in Hospitalized Patients. J. F. Kurtzke. A. M. A. Arch. Neurol. & Psychiat. 76:175-184 (Aug.) 1956 [Chicago].

At the Bronx Veterans Administration hospital over 300 patients with a diagnosis of multiple sclerosis were hospitalized between 1944 and 1953, but in some of these the data for diagnosis were insufficient. This paper is concerned with the 220 patients in whom the diagnosis was definite. These patients were divided into two groups. Group A consisted of 175 patients whose present episode was of two years' duration or less before hospitalization. Group B was composed of 45 patients the duration of whose present exacerbation exceeded two years before admission and averaged four and one-half years. No patient improved whose present exacerbation had persisted for more than two years before admission. Of the 175 patients in whom the present episode had lasted less than two years, 33% improved, 50% had no change, and 17% became worse during a mean hospital stay of three and a half months. Thus one out of three patients improved while in the hospital with an episode that had persisted for less than two years before admission. Follow-up studies after hospitalization in one-third of this group revealed only three patients who improved later but who had not improved in the hospital. It was felt that the period of hospitalization, which averaged three and a half months, was sufficient for the investigation of possible prognostic features. The outcome of the present episode could not be correlated with the total duration of illness, the age on admission or onset, the type of neurological involvement, the severity of status on admission, the prior nature of the illness, the laboratory findings, the month or year of admission, or the month of onset of acute attacks.

Improvement or remission was inversely related to the duration of the episode before admission. Of the 28 patients in whom the present episode had existed less than 7 days before admission, 24 improved, 2 remained unchanged, and 2 became worse; of the 14 in whom the present episode had existed between 8 and 14 days, 9 improved and 5 remained unchanged; of the 26 in whom the episode had existed for from 15 to 31 days, 10 improved, 14 remained unchanged, and 2 became worse; of the 75 in whom the episode had existed for from 1 to 12 months, 12 improved, 45 remained unchanged, and 18 became worse; and of the 29 in whom the episode had lasted between one and two years, 2 improved, 22 remained unchanged, and 5 became worse. This relationship of improvement to the duration of the episode may provide a standard for comparison and prognosis in this disease.

GYNECOLOGY & OBSTETRICS

Neonatal Umbilicus as a Source of Streptococcal Infections in a Maternity Unit. J. M. Boissard and B. Eton. Brit. M. J. 2:574-576 (Sept. 8) 1956 [London, England].

Pyrexia developed suddenly in a puerperal woman six days after an uneventful delivery. Mother and infant were removed to the isolation ward. Culture of the mother's vaginal swab yielded a heavy growth of Streptococcus pyogenes type 9. Nose and throat swabs were cultured from the ward staff and vaginal, nose, and throat swabs from all patients. None showed Str. pyogenes. A midwife, who had been working on the ward for only a week, went on leave two days before pyrexia developed in the puerperal woman. Acute tonsillitis, later shown to be due to Str. pyogenes type 9, developed in the midwife while she was at home, on the same day the puerperal woman had shown pyrexia. The infections in the mother and midwife manifesting themselves on the same day suggested a common source rather than one that was derived from one or the other, and the findings in the infant (cultures from throat and umbilical cord yielding Str. pyogenes type 9) prompted investigation of the nursery from this point of view. Cultures of swabs of the umbilicus of four infants who had been discharged from the nursery yielded Str. pyogenes type 9. Although these infants were widely dispersed at the time of this investigation, it seems certain that they acquired their umbilical infection in the ward nursery—the one environment originally common to all.

The authors show that the infections in the adults were accidents in what was primarily a series of infections in infants. There was never a time from the beginning of the earliest-known infection until the closure of the ward when the nursery was free from infection. Nothing is known about how or when infection entered the nursery, but it seems reasonable to suppose that the most likely route was via an attendant who was in the early stages of an unrecognized infection. The outbreak demonstrates the following points: 1. In a maternity hospital the nursery was the source of infections due to Str. pyogenes. 2. Without investigating the nursery it would have been impossible to find a connecting link between the infected adults or to detect the source of their infection. 3. If the nursery had not been investigated, it might not have been possible to control the outbreak of streptococcic infections. The authors make a plea for bacteriological investigation of the nursery whenever a case of streptococcic infection is found in a mother or a member of the staff.

The Combination of Prednisone and Methylandrostendiol in the Treatment of Advanced Cancer of the Uterus. G. Pescetto. Minerva ginec. 8:552-556 (July 15) 1956 (In Italian) [Turin, Italy].

Fourteen patients with cancer of the uterus in an advanced stage were treated with a combination of prednisone and methylandrostendiol. The author divided the patients into three groups. To the first group belonged six patients with uterine cancer located in the portio or in the body of the uterus. Surgical intervention had to be excluded because of the advanced stage of the disease. These patients were subjected to roentgenotherapy for a minimum of 9,000 r and a maximum of 12,000 r. Five of the six patients could no longer tolerate irradiation. To the second group belonged five patients with relapse of cancer of the uterus. These patients had received from 9,000 to 12,000 r. Severe pain was present. To the third group belonged three patients with cancer of the portio who received radium and roentgenotherapy. Marked cachexia and severe pain were present.

The dose of the combination was 100 to 150 mg. of prednisone and 100 to 150 mg. of methylandrostendiol, depending upon the condition of the patient. Treatment lasted 20 days, and in five patients it was started again after a 10-day interval. For the first five or six days after the treatment, 10 to 15 mg. of prednisone per day was given. Pain was markedly relieved in 80% of the patients, and in the others it was diminished. The general and psychic condition of the patients improved. The combination of the two drugs protected the patients against x-ray sickness. The negative aspect of the treatment lies in the short duration of the results, the lack of any evident effect of the drugs on the neoplasia, and the very high expense involved.

Cancer of the Cervix, an Appraisal. J. V. Meigs. Am. J. Obst. & Gynec. 72:467-478 (Sept.) 1956 [St. Louis].

Meigs reviews the results obtained in 130 patients with cervical cancer in whom he personally performed the operation. The following patients survived five years: Of 61 who received surgical treatment only, 55 (90%); of 29 who were subjected to surgery after radiation had failed, 18 (62%); of 20 who were operated on after cure had been achieved by irradiation (no cancer found at operation) 19 (95%); of 10 in whom surgery was followed by postoperative irradiation (surgical failures), 3 (30%); and of 10 who received irradiation before and after surgery (radiation and surgical failures), one (10%). The 10-year survival rates indicate that those treated by surgery alone obtained results that were as favorable as those treated by irradiation plus surgery, but it should be remembered that the patients operated upon were probably the best-risk patients. It is conceivable that surgery will cure some radiation failures and that radiation will cure some of the surgical failures. This definitely indicates the importance of selection. The author hopes that study of the sensitization response and of the radiation reaction will help in the work of selection. The cure of patients in whom the lymph nodes have been invaded is excellent, running from 31 to 55% in the five-year results and to from 25 to 40% in the 10-year results. Radiation therapy seems to be as effective in patients with as without invasion of the lymph nodes. This study suggests that radiation and surgery are complementary and that results in the hands of experts will be good whichever method is used, but it does show the importance of selection.

The Pregnant Diabetic: A Report of 200 Cases. S. G. Clayton. J. Obst. & Gynæc. Brit. Emp. 63:532-541 (Aug.) 1956 [London, England].

This report is based on the records of 201 pregnancies in 176 diabetic patients. Although delivery was carried out by cesarian section in 122 patients and by abdominal hysterectomy in 6, and delivery was induced in most of the others, there was only one maternal death. This low maternal death rate, however, does not imply that there is no risk; on the contrary, the risk is great in those in whom albuminuria occurs during the early months of pregnancy, in those with retinal hemorrhages, and in those with hypertension. These patients may not all have the same pathological changes, but many probably have glomerulosclerosis (Kimmelstiel-Wilson syndrome). The fetal mortality remains high when pregnancy is complicated by diabetes. The three multiple pregnancies (two twin and one triplet pregnancy) produced only two living infants. In the 198 pregnancies with single fetuses only 132 infants remained alive; the pregnancy was terminated in 8 cases, spontaneous abortion occurred in 7, stillbirth in 21, and neonatal death in 30. The weight of the infants of diabetic mothers is often excessive, but the overgrowth of the placenta is even more pronounced, being about 25% instead of the normal 17% of the fetal weight at 36 weeks of pregnancy. Hydramnios occurred in 48% of the single-fetus pregnancies.

If diabetic pregnant women are permitted to go to full term, the fetus not infrequently dies in utero during the last four weeks of pregnancy. On the other hand, if the infant is delivered prematurely, there is a considerable risk of neonatal death. The relative frequency of these two modes of death will depend on the obstetric management, and since most of these women were delivered at about the 36th week the stillbirth rate in this series is relatively low. All the intrauterine deaths recorded here occurred between the 32nd and 36th weeks of pregnancy, and, because of the author's policy of delivery at about the 36th week, the risk of intrauterine death after that time could not be ascertained. If control of the diabetes is poor, the number of intrauterine deaths is increased, but even with good control not all these deaths will be prevented. The neonatal deaths occurred most frequently after cesarian section, probably because that was the commonest mode of delivery (122 cases). The child is delivered together with the usual flood of amniotic liquor. Often large quantities of fluid are aspirated from the air passages and from the stomach. All goes well for a time, but after a few hours respiratory distress begins, with successive cyanotic attacks until circulatory failure occurs. This mode of death was seen in 23 of 30 cases, and in all those in which an autopsy was performed absorption atelectasis resulting from hyaline membrane formation in the air passages was found. The average time from birth to death was 13 hours.

A Comparative Study of Different Techniques for the Diagnosis of Cervical Carcinoma. H. E. Nieburgs. Am. J. Obst. & Gynec. 72:511-515 (Sept.) 1956 [St. Louis].

Not only racial, social, and age factors but also the techniques employed help to explain the conflicting reports on the number of cases of cervical carcinoma detected by exfoliative cytology. Three techniques were compared in 154 patients, including 73 women with different epithelial lesions of the cervix. A cotton applicator was used to prepare a smear from the posterior fornix. The endocervical smear was obtained by insertion of the cotton applicator into the cervical canal and twirling it around a few times against the squamocolumnar junction. The smear was made by rolling the cotton applicator in the counterclockwise direction on the slide in order to secure complete transfer of the cervical mucus plug to the glass. The third technique employed was the use of Ayre's wooden spatula for the scraping of the cervix without prior removal of the mucus plug. The smear from the posterior fornix was less satisfactory than those obtained from the endocervix. The occurrence of false-negative smears obtained from the endocervix seems to depend on the order in which the smears are taken. The first smear made appears to be the more satisfactory, apparently because of the fact that the endocervical mucus plug, which usually carries a larger number of cancer cells, was utilized. Smears obtained with the cotton applicator or spatula following the removal of the mucus plug may result in false-negative slides. Although in positive cases the spatula smears contain a larger number of cells, for routine cancer detection less time seems to be required for the interpretation of slides when the cotton applicator smears are used.

Pelvic Carcinoma Following Irradiation for Benign Gynecological Diseases. J. P. Palmer and D. W. Spratt. Am. J. Obst. & Gynec. 72:497-505 (Sept.) 1956 [St. Louis].

The authors first studied the records of 377 women with cancer of the body of the uterus seen at the department of gynecology of Rosewell Park Memorial Institute between 1947 and 1952. They found that 21 patients had had previous irradiation of the pelvis, 17 for benign uterine conditions and 4 for nonuterine pelvic cancer. The average interval between the irradiation and the subsequent corpus cancer was 11.7 years. At Rosewell Park Memorial Institute, before 1940, the treatment of benign uterine conditions with radium or x-ray or both was common practice. Since 1940, irradiation for benign bleeding has been given only if surgery was contraindicated. This change of policy came with the realization that occasionally a patient who had had irradiation for benign bleeding would return with uterine or other pelvic cancer. Realizing the long intervals elapsing between irradiation and the development of cancer, the authors considered in their further investigations only patients treated prior to 1941. Questionnaires were mailed to 1,670 patients who had been treated between 1930 and 1940 with radium and/or x-ray for benign uterine abnormalities. The women were asked (1) their opinion as to whether the symptoms were relieved, (2) Whether these symptoms later recurred, and (3) Whether any pelvic operation or irradiation was subsequently necessary. If question 3 was answered "yes," the doctor and/or hospital was then asked for full data. Adequate replies were received from 721 patients. All of these patients were followed for 12 or more years; the average follow-up was 16.08 years. It was found that pelvic cancers had developed in 61 or 8.4% of the 721 patients. The authors also cite figures on the expected incidence of cancer, comment on the role of fibroids and endometrial hyperplasia in the causation of cancer of the body of the uterus, and compare radiation dosages.

They conclude that their detection of a higher incidence of pelvic cancer developing after irradiation can be explained by the fact that the follow-up of other investigators was not long enough. They found a rather low incidence of menorrhagia of the menopause in patients with cancer of the body of the uterus, and they deduce from this that menorrhagia, or its underlying cause, is not a significant predisposing influence in the development of subsequent malignancy of the corpus uteri. They believe that the previous irradiation is, at least in part, responsible for the subsequent cancers. Also, since the patients with controlled cancer of the cervix did not show the high incidence of subsequent cancer of the adjacent pelvic structures, they believe that the relatively low irradiation dosage given the group with benign lesions caused some growth-stimulating influence that the higher, cancerocidal dosage did not cause. Irradiation castration should be used only in women who are not satisfactory surgical risks and, if used, should probably be given in dosage adequate to overcome the possible growth-stimulating influence. The authors continued their studies after they wrote this report, and in an addendum they add 25 patients to the 721 originally studied. They also add 10 pelvic cancers to the 61 mentioned in the paper. The shortest interval between irradiation and cancer development was 13 years and the longest 23 years; the average was 17.3 years.

The Outcome of Pregnancy Complicated by Threatened Abortion. E. P. N. Turnbull and J. Walker, J. Obst. & Gynæc. Brit. Emp. 63:553-559 (Aug.) 1956 [London, England].
